The Elements

Name	Symbol	Atomic Number	Atomic Mass*	Name	Symbol	Atomic Number	Atomic Mass*
Actinium	Ac	89	(227)	Mendelevium	Md	101	(258)
Aluminum	Al	13	26.98	Mercury	Hg	80	200.59
Americium	Am	95	(243)	Molybdenum	Mo	42	95.95
Antimony	Sb	51	121.76	Moscovium	Mc	115	(289)
Argon	Ar	18	39.79	Neodymium	Nd	60	144.24
Arsenic	As	33	74.92	Neon	Ne	10	20.18
Astatine	At	85	(210)	Neptunium	Np	93	(237)
Barium	Ba	56	137.33	Nickel	Ni	28	58.69
Berkelium	Bk	97	(249)	Nihonium	Nh	113	(285)
Beryllium	Be	4	9.012	Niobium	Nb	41	92.91
Bismuth	Bi	83	208.98	Nitrogen	N	7	14.01
Bohrium	Bh	107	(272)	Nobelium	No	102	(259)
Boron	B	5	10.81	Oganesson	Og	118	(294)
Bromine	Br	35	79.90	Osmium	Os	76	190.23
Cadmium	Cd	48	112.41	Oxygen	O	8	16.00
Calcium	Ca	20	40.08	Palladium	Pd	46	106.42
Californium	Cf	98	(252)	Phosphorus	P	15	30.97
Carbon	C	6	12.01	Platinum	Pt	78	195.08
Cerium	Ce	58	140.12	Plutonium	Pu	94	(239)
Cesium	Cs	55	132.91	Polonium	Po	84	(210)
Chlorine	Cl	17	35.45	Potassium	K	19	39.10
Chromium	Cr	24	52.00	Praseodymium	Pr	59	140.91
Cobalt	Co	27	58.93	Promethium	Pm	61	(145)
Copernicium	Cn	112	(285)	Protactinium	Pa	91	231.04
Copper	Cu	29	63.55	Radium	Ra	88	(226)
Curium	Cm	96	(247)	Radon	Rn	86	(222)
Darmstadtium	Ds	110	(281)	Rhenium	Re	75	186.21
Dubnium	Db	105	(262)	Rhodium	Rh	45	102.91
Dysprosium	Dy	66	162.5	Roentgenium	Rg	111	(280)
Einsteinium	Es	99	(252)	Rubidium	Rb	37	85.47
Erbium	Er	68	167.26	Ruthenium	Ru	44	101.07
Europium	Eu	63	151.96	Rutherfordium	Rf	104	(261)
Fermium	Fm	100	(257)	Samarium	Sm	62	150.36
Fleavorium	Fl	114	(287)	Scandium	Sc	21	44.96
Fluorine	F	9	19.00	Seaborgium	Sg	106	(266)
Francium	Fr	87	(223)	Selenium	Se	34	78.97
Gadolinium	Gd	64	157.25	Silicon	Si	14	28.08
Gallium	Ga	31	69.72	Silver	Ag	47	107.87
Germanium	Ge	32	72.63	Sodium	Na	11	22.99
Gold	Au	79	196.97	Strontium	Sr	38	87.62
Hafnium	Hf	72	178.49	Sulfur	S	16	32.06
Hassium	Hs	108	(277)	Tantalum	Ta	73	180.95
Helium	He	2	4.003	Technetium	Tc	43	(98)
Holmium	Ho	67	164.93	Tellurium	Te	52	127.6
Hydrogen	H	1	1.008	Tennessine	Ts	117	(293)
Indium	In	49	114.82	Terbium	Tb	65	158.93
Iodine	I	53	126.90	Thallium	Tl	81	204.38
Iridium	Ir	77	192.22	Thorium	Th	90	232.04
Iron	Fe	26	55.85	Thulium	Tm	69	168.93
Krypton	Kr	36	83.80	Tin	Sn	50	118.71
Lanthanum	La	57	138.91	Titanium	Ti	22	47.87
Lawrencium	Lr	103	(262)	Tungsten	W	74	183.84
Lead	Pb	82	207.2	Uranium	U	92	238.03
Lithium	Li	3	6.938	Vanadium	V	23	50.94
Livermorium	Lv	116	(291)	Xenon	Xe	54	131.29
Lutetium	Lu	71	174.97	Ytterbium	Yb	70	173.05
Magnesium	Mg	12	24.30	Yttrium	Y	39	88.91
Manganese	Mn	25	54.94	Zinc	Zn	30	65.38
Meitnerium	Mt	109	(276)	Zirconium	Zr	40	91.22

*Values in parentheses represent the mass number of the most stable isotope.

DETAILED CONTENTS

Filip Fuxa/fyletto/123RF

Chapter 1 | Keys to Studying Chemistry: Definitions, Units, and Problem Solving 2

1.1 Some Fundamental Definitions 3

The States of Matter 3
The Properties of Matter and Its Changes 4
The Central Theme in Chemistry 8
The Importance of Energy in the Study of Matter 8

1.2 The Scientific Approach: Developing a Model 10

1.3 Units of Measurement 11

General Features of SI Units 11

Some Important SI Units in Chemistry 12
Temperature Scales 15

1.4 Uncertainty In Measurement: Significant Figures 18

Determining Which Digits Are Significant 18
Significant Figures: Calculations and Rounding Off 20
Precision, Accuracy, and Instrument Calibration 22

1.5 Units and Conversion Factors in Calculations 23

Constructing and Choosing Conversion Factors 23
Converting Between Unit Systems 24
A Systematic Approach to Solving Chemistry Problems 24
Extensive and Intensive Properties 30

CHAPTER REVIEW GUIDE 31

PROBLEMS 35

Chapter 2 | The Components of Matter 40

2.1 Elements, Compounds, and Mixtures: An Atomic Overview 41

Substances 42
Mixtures 42
Classification and Separation of Mixtures 43

2.2 The Observations That Led to an Atomic View of Matter 46

Mass Conservation 46
Definite Composition 47
Multiple Proportions 49
Dalton's Atomic Theory 50

2.3 The Observations That Led to the Nuclear Atom Model 52

Discovery of the Electron and Its Properties 52
Discovery of the Atomic Nucleus 54

2.4 The Atomic Theory Today 55

Structure of the Atom 55
Atomic Number, Mass Number, and Atomic Symbol 56
Isotopes 57
Atomic Masses of the Elements 58

2.5 Elements: A First Look at the Periodic Table 61

2.6 Compounds: Introduction to Bonding 64

The Formation of Ionic Compounds 64
The Formation of Covalent Substances 66

2.7 Compounds: Formulas, Names, and Masses 68

Ionic Compounds 68
Acid Names from Anion Names 73

Binary Covalent Compounds 74

The Simplest Organic Compounds: Straight-Chain Alkanes 75

Molecular Masses from Chemical Formulas 76

Representing Molecules with Formulas and Models 78

An Overview of the Components of Matter 79

CHAPTER REVIEW GUIDE 81

PROBLEMS 84

Inga Spence/Alamy Stock Photo

Chapter 3 | Stoichiometry of Formulas and Equations 92

3.1 The Mole 93

Defining the Mole 93
Determining Molar Mass 94
Converting Between Amount, Mass, and Number of Chemical Entities 95
The Importance of Mass Percent 99

3.2 Determining the Formula of an Unknown Compound 102

Empirical Formulas 103
Molecular Formulas 104

3.3 Writing and Balancing Chemical Equations 107

3.4 Calculating Quantities of Reactant and Product 113

Stoichiometrically Equivalent Molar Ratios from the Balanced Equation 113
Reactions That Involve a Limiting Reactant 116

Theoretical, Actual, and Percent Reaction Yields 122

CHAPTER REVIEW GUIDE 125

PROBLEMS 130

Chapter 4 | Three Major Classes of Chemical Reactions 140

4.1 Solution Concentration and the Role of Water as a Solvent 141

Expressing Concentration in Terms of Molarity 142
Amount-Mass-Number Conversions Involving Solutions 142
Preparing and Diluting Molar Solutions 143
The Polar Nature of Water 147
Ionic Compounds in Water 147
Covalent Compounds in Water 151

4.2 Precipitation Reactions 152

The Key Event: Formation of a Solid from Dissolved Ions 152
Predicting Whether a Precipitate Will Form 154

Stoichiometry of Precipitation Reactions 157

4.3 Acid-Base Reactions 160

The Key Event: Formation of H_2O from H^+ and OH^- 163
Stoichiometry of Acid-Base Reactions: Acid-Base Titrations 166

4.4 Oxidation-Reduction (Redox) Reactions 169

The Key Event: Movement of Electrons Between Reactants 169
Some Essential Redox Terminology 170
Using Oxidation Numbers to Monitor Electron Charge 171

Stoichiometry of Redox Reactions: Redox Titrations 174

4.5 Elements in Redox Reactions 176

Combination Redox Reactions 176
Decomposition Redox Reactions 178
Displacement Redox Reactions and Activity Series 179
Combustion Reactions 181

4.6 The Reversibility of Reactions and the Equilibrium State 184

CHAPTER REVIEW GUIDE 186

PROBLEMS 192

Chapter 5 | Gases and the Kinetic-Molecular Theory 200

5.1 An Overview of the Physical States of Matter 201

5.2 Gas Pressure and Its Measurement 203

Measuring Gas Pressure: Barometers and Manometers 203
Units of Pressure 205

5.3 The Gas Laws and Their Experimental Foundations 206

The Relationship Between Volume and Pressure: Boyle's Law 207
The Relationship Between Volume and Temperature: Charles's Law 208
The Relationship Between Volume and Amount: Avogadro's Law 210

Gas Behavior at Standard Conditions 211
The Ideal Gas Law 212
Solving Gas Law Problems 213

5.4 Rearrangements of the Ideal Gas Law 218

The Density of a Gas 218
The Molar Mass of a Gas 220
The Partial Pressure of Each Gas in a Mixture of Gases 221
The Ideal Gas Law and Reaction Stoichiometry 225

5.5 The Kinetic-Molecular Theory: A Model for Gas Behavior 227

How the Kinetic-Molecular Theory Explains the Gas Laws 227

Effusion and Diffusion 232
The Chaotic World of Gases: Mean Free Path and Collision Frequency 234

CHEMICAL CONNECTIONS TO ATMOSPHERIC SCIENCE:
HOW THE GAS LAWS APPLY TO EARTH'S ATMOSPHERE 235

5.6 Real Gases: Deviations from Ideal Behavior 237

Effects of Extreme Conditions on Gas Behavior 237
The van der Waals Equation: Adjusting the Ideal Gas Law 239

CHAPTER REVIEW GUIDE 240

PROBLEMS 244

Thinkstock/Stockbyte/Getty Images

Chapter 6 | Thermochemistry: Energy Flow and Chemical Change 252

6.1 Forms of Energy and Their Interconversion 253

Defining the System and Its Surroundings 254
Energy Change (ΔE): Energy Transfer to or from a System 254
Heat and Work: Two Forms of Energy Transfer 255
The Law of Energy Conservation 257
Units of Energy 258
State Functions and the Path Independence of the Energy Change 259
Calculating Pressure-Volume Work (PV Work) 260

6.2 Enthalpy: Changes at Constant Pressure 261

The Meaning of Enthalpy 261
Comparing ΔE and ΔH 262
Exothermic and Endothermic Processes 262

6.3 Calorimetry: Measuring the Heat of a Chemical or Physical Change 264

Specific Heat Capacity 264
The Two Major Types of Calorimetry 266

6.4 Stoichiometry of Thermochemical Equations 270

6.5 Hess's Law: Finding ΔH of Any Reaction 272

6.6 Standard Enthalpies of Reaction ($\Delta H^\circ_{\text{rxn}}$) 274

Formation Equations and Their Standard Enthalpy Changes 275
Determining $\Delta H^\circ_{\text{rxn}}$ from ΔH°_f Values for Reactants and Products 276

CHEMICAL CONNECTIONS TO ATMOSPHERIC SCIENCE:
THE FUTURE OF ENERGY USE 278

CHAPTER REVIEW GUIDE 280

PROBLEMS 283

Chapter 7 | Quantum Theory and Atomic Structure 290

7.1 The Nature of Light 291

The Wave Nature of Light 292
The Particle Nature of Light 295

7.2 Atomic Spectra 298

Line Spectra and the Rydberg Equation 298
The Bohr Model of the Hydrogen Atom 299
The Energy Levels of the Hydrogen Atom 301

TOOLS OF THE LABORATORY:
SPECTROMETRY IN CHEMICAL ANALYSIS 304

7.3 The Wave-Particle Duality of Matter and Energy 306

The Wave Nature of Electrons 306
The Particle Nature of Photons 307
Wave-Particle Duality 308
Heisenberg's Uncertainty Principle 309

7.4 The Quantum-Mechanical Model of the Atom 310

The Atomic Orbital and the Probable Location of the Electron 310
Quantum Numbers 311
Shapes of Atomic Orbitals 315
The Special Case of Energy Levels in the Hydrogen Atom 318

CHAPTER REVIEW GUIDE 318

PROBLEMS 321

Chapter 8 | Electron Configuration and Chemical Periodicity 326

8.1 Characteristics of Many-Electron Atoms 328

The Pauli Exclusion Principle 328
Electrostatic Effects and Energy-Level Splitting 328

8.2 The Quantum-Mechanical Model and the Periodic Table 330

Building Up Period 1 331
Building Up Period 2 331
Building Up Period 3 333

Building Up Period 4: The First Transition Series 334

General Principles of Electron Configurations 335
Intervening Series: Transition and Inner Transition Elements 337
Similar Electron Configurations Within Groups 337

8.3 Trends in Three Atomic Properties 340

Trends in Atomic Size 340

Trends in Ionization Energy 342
Trends in Electron Affinity 346

8.4 Atomic Properties and Chemical Reactivity 347

Trends in Metallic Behavior 347
Properties of Monatomic Ions 349

CHAPTER REVIEW GUIDE 355

PROBLEMS 357

Stephen Frisch/McGraw Hill

Chapter 9 | Models of Chemical Bonding 362

9.1 Atomic Properties and Chemical Bonds 363

The Three Ways Elements Combine 363
Lewis Symbols and the Octet Rule 365

9.2 The Ionic Bonding Model 366

Why Ionic Compounds Form: The Importance of Lattice Energy 367
Periodic Trends in Lattice Energy 370
How the Model Explains the Properties of Ionic Compounds 372

9.3 The Covalent Bonding Model 373

The Formation of a Covalent Bond 373
Bonding Pairs and Lone Pairs 374
Properties of a Covalent Bond: Order, Energy, and Length 374

How the Model Explains the Properties of Covalent Substances 377

TOOLS OF THE LABORATORY: INFRARED SPECTROSCOPY 378

9.4 Bond Energy and Chemical Change 379

Changes in Bond Energy: Where Does $\Delta H_{\text{rxn}}^\circ$ Come From? 379
Using Bond Energies to Calculate $\Delta H_{\text{rxn}}^\circ$ 380
Bond Strengths and the Heat Released from Fuels, Foods, and Explosives 383

9.5 Between the Extremes: Electronegativity and Bond Polarity 384

Electronegativity 384

Bond Polarity and Partial Ionic Character 385

The Gradation in Bonding Across a Period 387

9.6 An Introduction to Metallic Bonding 389

The Electron-Sea Model 389
How the Model Explains the Properties of Metals 389

CHAPTER REVIEW GUIDE 391

PROBLEMS 393

Chapter 10 | The Shapes of Molecules 398

10.1 Depicting Molecules and Ions with Lewis Structures 399

Applying the Octet Rule to Write Lewis Structures 399
Resonance: Delocalized Electron-Pair Bonding 404
Formal Charge: Selecting the More Important Resonance Structure 406
Lewis Structures for Exceptions to the Octet Rule 408

10.2 Valence-Shell Electron-Pair Repulsion (VSEPR) Theory 412

Electron-Group Arrangements and Molecular Shapes 413
The Molecular Shape with Two Electron Groups (Linear Arrangement) 414

Molecular Shapes with Three Electron Groups (Trigonal Planar Arrangement) 414

Molecular Shapes with Four Electron Groups (Tetrahedral Arrangement) 415

Molecular Shapes with Five Electron Groups (Trigonal Bipyramidal Arrangement) 417

Molecular Shapes with Six Electron Groups (Octahedral Arrangement) 418

Using VSEPR Theory to Determine Molecular Shape 418

Molecular Shapes with More Than One Central Atom 421

10.3 Molecular Shape and Molecular Polarity 423

Bond Polarity, Bond Angle, and Dipole Moment 423
The Effect of Molecular Polarity on Behavior 425

CHEMICAL CONNECTIONS TO SENSORY PHYSIOLOGY: MOLECULAR SHAPE AND BIOLOGICAL RECEPTORS 426

CHAPTER REVIEW GUIDE 427

PROBLEMS 431

Charles D. Winters/Timeframe Photography/
McGraw Hill

Chapter 11 | Theories of Covalent Bonding 436

- 11.1 Valence Bond (VB) Theory and Orbital Hybridization 437**
The Central Themes of VB Theory 437
Types of Hybrid Orbitals 438
- 11.2 Modes of Orbital Overlap and the Types of Covalent Bonds 446**
Orbital Overlap in Single and Multiple Bonds 446
Orbital Overlap and Rotation Within a Molecule 449

- 11.3 Molecular Orbital (MO) Theory and Electron Delocalization 449**
The Central Themes of MO Theory 450
Homonuclear Diatomic Molecules of Period 2 Elements 452
Two Heteronuclear Diatomic Molecules: HF and NO 456
Two Polyatomic Molecules: Benzene and Ozone 457

CHAPTER REVIEW GUIDE 458
PROBLEMS 461

Chapter 12 | Intermolecular Forces: Liquids, Solids, and Phase Changes 466

- 12.1 Types of Intermolecular Forces 467**
Relative Strength of Intramolecular and Intermolecular Forces 468
Ion-Dipole Forces 469
Dipole-Dipole Forces 469
The Hydrogen Bond 470
Dispersion (London) Forces 472
- 12.2 An Overview of Physical States and Phase Changes 475**
A Kinetic-Molecular View of the Three States 475
Types of Phase Changes and Their Enthalpies 476
- 12.3 Quantitative Aspects of Phase Changes 478**
Heat Involved in Phase Changes 478
The Equilibrium Nature of Phase Changes 481
Phase Diagrams: Effect of Pressure and Temperature on Physical State 485

- 12.4 Properties of the Liquid State 488**
Surface Tension 488
Capillarity 489
Viscosity 489
- 12.5 The Uniqueness of Water 490**
Solvent Properties of Water 490
Thermal Properties of Water 491
Surface Properties of Water 491
The Unusual Density of Solid Water 491
- 12.6 The Solid State: Structure, Properties, and Bonding 492**
Structural Features of Solids 493
TOOLS OF THE LABORATORY:
X-RAY DIFFRACTION ANALYSIS AND SCANNING TUNNELING MICROSCOPY 500
Types and Properties of Crystalline Solids 501
Amorphous Solids 504

Bonding in Solids: Molecular Orbital Band Theory 505

- 12.7 Advanced Materials 507**
Electronic Materials 507
Liquid Crystals 508
Ceramic Materials 511
Polymeric Materials 513
Nanotechnology: Designing Materials Atom by Atom 518

CHAPTER REVIEW GUIDE 520
PROBLEMS 523

Chapter 13 | The Properties of Mixtures: Solutions and Colloids 530

13.1 Types of Solutions: Intermolecular Forces and Solubility 531

Intermolecular Forces in Solution 532
Liquid Solutions and the Role of Molecular Polarity 533
Gas Solutions and Solid Solutions 537

13.2 Why Substances Dissolve: Breaking Down the Solution Process 538

The Heat of Solution and Its Components 538
The Heat of Hydration: Dissolving Ionic Solids in Water 539
The Solution Process and the Change in Entropy 542

13.3 Solution Equilibrium and Factors Affecting Solubility 544

Effect of Temperature on Solubility 544
Effect of Pressure on Solubility 546

13.4 Concentration Terms 547

Molarity and Molality 547
Parts of Solute by Parts of Solution 549
Interconverting Concentration Terms 551

13.5 Colligative Properties of Solutions 552

Nonvolatile Nonelectrolyte Solutions 553
Using Colligative Properties to Find Solute Molar Mass 558
Volatile Nonelectrolyte Solutions 559
Strong Electrolyte Solutions 559

Applications of Colligative Properties 562

13.6 The Structure and Properties of Colloids 563

CHEMICAL CONNECTIONS TO ENVIRONMENTAL ENGINEERING: SOLUTIONS AND COLLOIDS IN WATER PURIFICATION 565

CHAPTER REVIEW GUIDE 567

PROBLEMS 571

Chapter 14 | Periodic Patterns in the Main-Group Elements 580

14.1 Hydrogen, the Simplest Atom 581

Where Hydrogen Fits in the Periodic Table 581
Isotopes of Hydrogen 582
Highlights of Hydrogen Chemistry 582

14.2 Trends Across the Periodic Table: The Period 2 Elements 583

14.3 Group 1: The Alkali Metals 586

Why the Alkali Metals Are Unusual Physically 586
Why the Alkali Metals Are So Reactive 586

14.4 Group 2: The Alkaline Earth Metals 588

How the Alkaline Earth and Alkali Metals Compare Physically 589
How the Alkaline Earth and Alkali Metals Compare Chemically 589

14.5 Group 13: The Boron Family 591

How the Transition Elements Influence This Group's Properties 591

Features That First Appear in This Group's Chemical Properties 591
Highlights of Boron Chemistry 593

14.6 Group 14: The Carbon Family 594

How the Type of Bonding Affects Physical Properties 594
How Bonding Changes in This Group's Compounds 597
Highlights of Carbon Chemistry 597
Highlights of Silicon Chemistry 598

14.7 Group 15: The Nitrogen Family 599

The Wide Range of Physical Behavior 599
Patterns in Chemical Behavior 601
Highlights of Nitrogen Chemistry 602
Highlights of Phosphorus Chemistry 605

14.8 Group 16: The Oxygen Family 607

How the Oxygen and Nitrogen Families Compare Physically 607
How the Oxygen and Nitrogen Families Compare Chemically 609

Highlights of Oxygen Chemistry: Range of Oxide Properties 610
Highlights of Sulfur Chemistry 610

14.9 Group 17: The Halogens 611

Physical Behavior of the Halogens 612
Why the Halogens Are So Reactive 612
Highlights of Halogen Chemistry 614

14.10 Group 18: The Noble Gases 616

How the Noble Gases and Alkali Metals Contrast Physically 616
Compounds of Noble Gases 616

CHAPTER REVIEW GUIDE 618

PROBLEMS 619

monticello/Shutterstock

Chapter 15 | Organic Compounds and the Atomic Properties of Carbon 626

15.1 The Special Nature of Carbon and the Characteristics of Organic Molecules 627

The Structural Complexity of Organic Molecules 627
The Chemical Diversity of Organic Molecules 628

15.2 The Structures and Classes of Hydrocarbons 629

Carbon Skeletons and Hydrogen Skins 630
Alkanes: Hydrocarbons with Only Single Bonds 633
Dispersion Forces and the Physical Properties of Alkanes 635
Constitutional Isomerism 635
Chiral Molecules and Optical Isomerism 636
Alkenes: Hydrocarbons with Double Bonds 638

Restricted Rotation and Geometric (*cis-trans*) Isomerism 639
Alkynes: Hydrocarbons with Triple Bonds 640
Aromatic Hydrocarbons: Cyclic Molecules with Delocalized π Electrons 641

TOOLS OF THE LABORATORY: NUCLEAR MAGNETIC RESONANCE (NMR) SPECTROSCOPY 643

15.3 Some Important Classes of Organic Reactions 644

Types of Organic Reactions 645
The Redox Process in Organic Reactions 647

15.4 Properties and Reactivities of Common Functional Groups 648

Functional Groups with Only Single Bonds 648
Functional Groups with Double Bonds 653

Functional Groups with Both Single and Double Bonds 656
Functional Groups with Triple Bonds 660

15.5 The Monomer-Polymer Theme I: Synthetic Macromolecules 661

Addition Polymers 661
Condensation Polymers 662

15.6 The Monomer-Polymer Theme II: Biological Macromolecules 663

Sugars and Polysaccharides 664
Amino Acids and Proteins 665
Nucleotides and Nucleic Acids 668

CHEMICAL CONNECTIONS TO GENETICS AND FORENSICS: DNA SEQUENCING AND FINGERPRINTING 673

CHAPTER REVIEW GUIDE 675

PROBLEMS 678

Chapter 16 | Kinetics: Rates and Mechanisms of Chemical Reactions 686

16.1 Focusing on Reaction Rate 687

16.2 Expressing the Reaction Rate 689

Average, Instantaneous, and Initial Reaction Rates 690
Expressing Rate in Terms of Reactant and Product Concentrations 692

16.3 The Rate Law and Its Components 694

Some Laboratory Methods for Determining the Initial Rate 695
Determining Reaction Orders 695
Determining the Rate Constant 699

16.4 Integrated Rate Laws: Concentration Changes over Time 703

Integrated Rate Law and Reaction Half-Life for First-Order Reactions 703
Integrated Rate Law and Reaction Half-Life for Second-Order Reactions 707

Integrated Rate Law and Reaction Half-Life for Zero-Order Reactions 709
Determining Reaction Orders from an Integrated Rate Law 709

16.5 Theories of Chemical Kinetics 711

Collision Theory: Basis of the Rate Law 711
Transition State Theory: What the Activation Energy Is Used For 713
The Effect of Temperature on Rate 715

16.6 Reaction Mechanisms: The Steps from Reactant to Product 718

Elementary Reactions and Molecularity 718
The Rate-Determining Step of a Reaction Mechanism 720
Correlating the Mechanism with the Rate Law 721

16.7 Catalysis: Speeding Up a Reaction 724

The Basis of Catalytic Action 725
Homogeneous Catalysis 726
Heterogeneous Catalysis 726
Kinetics and Function of Biological Catalysts 727

CHEMICAL CONNECTIONS TO ATMOSPHERIC SCIENCE: DEPLETION OF EARTH'S OZONE LAYER 730

CHAPTER REVIEW GUIDE 731

PROBLEMS 735

Ingram Publishing/SuperStock

Chapter 17 | Equilibrium: The Extent of Chemical Reactions 744

17.1 The Equilibrium State and the Equilibrium Constant 745

17.2 The Reaction Quotient and the Equilibrium Constant 748

The Changing Value of the Reaction Quotient 748

Writing the Reaction Quotient in Its Various Forms 749

17.3 Expressing Equilibria with Pressure Terms: Relation Between K_c and K_p 755

17.4 Comparing Q and K to Determine Reaction Direction 756

17.5 How to Solve Equilibrium Problems 759

Using Quantities to Find the Equilibrium Constant 759

Using the Equilibrium Constant to Find Quantities 762

Problems Involving Mixtures of Reactants and Products 768

17.6 Reaction Conditions and Equilibrium: Le Châtelier's Principle 769

The Effect of a Change in Concentration 770

The Effect of a Change in Pressure (Volume) 773

The Effect of a Change in Temperature 775

The Lack of Effect of a Catalyst 777

CHEMICAL CONNECTIONS TO INDUSTRIAL PROCESSES:
USING EQUILIBRIUM AND KINETICS IN THE SYNTHESIS OF AMMONIA 780

CHAPTER REVIEW GUIDE 781

PROBLEMS 786

Chapter 18 | Acid-Base Equilibria 794

18.1 Release of H^+ and OH^- and the Arrhenius Definition 796

Arrhenius Acids and Bases 796

Arrhenius Acid-Base Reactions 796

18.2 Proton Transfer and the Brønsted-Lowry Acid-Base Definition 797

Conjugate Acid-Base Pairs 798

Relative Acid-Base Strength and the Net Direction of Reaction 799

18.3 Autoionization of Water and the pH Scale 802

The Equilibrium Nature of Autoionization: The Ion-Product Constant for Water (K_w) 802

Expressing the Hydronium Ion Concentration: The pH Scale 804

18.4 Strong Acids and Bases and pH Calculations 806

Strong Acids 806

Strong Bases 807

Calculating pH for Strong Acids and Bases 807

18.5 Weak Acids and Their Equilibria Calculations 808

The Acid Dissociation Constant (K_a) 808Finding K_a , Given Concentrations 811Finding Concentrations, Given K_a 812
The Effect of Concentration on the Extent of Acid Dissociation 813

The Behavior of Polyprotic Acids 815

18.6 Molecular Properties and Acid Strength 818

Acid Strength of Binary Acids 818

Acid Strength of Oxoacids 818

Acidity of Hydrated Metal Ions 819

18.7 Weak Bases and Their Relation to Weak Acids 820

Molecules as Weak Bases: Ammonia and the Amines 821

Anions of Weak Acids as Weak Bases 823

The Relation Between K_a and K_b of a Conjugate Acid-Base Pair 823

18.8 Acid-Base Properties of Salt Solutions 825

The Effect of Cations on pH 826

The Effect of Anions on pH 826

Determining the Relative pH of a Cation/Anion Combination (Salt) 827

18.9 Generalizing the Brønsted-Lowry Concept: The Leveling Effect 831

18.10 Electron-Pair Donation and the Lewis Acid-Base Definition 832

Molecules as Lewis Acids 832

Metal Cations as Lewis Acids 833

An Overview of Acid-Base Definitions 834

CHAPTER REVIEW GUIDE 835

PROBLEMS 839

Buttchi 3 Sha Life/Shutterstock

Chapter 19 | Ionic Equilibria in Aqueous Systems 848

19.1 The Common-Ion Effect 849

19.2 Equilibria of Acid-Base Buffers 851

What a Buffer Is and How It Works 852
The Henderson-Hasselbalch Equation 856
Buffer Capacity and Buffer Range 857
Preparing a Buffer 859

19.3 Acid-Base Titration Curves 861

Strong Acid–Strong Base Titration Curves 861
Weak Acid–Strong Base Titration Curves 864
Weak Base–Strong Acid Titration Curves 868
Monitoring pH with Acid-Base Indicators 870
Titration Curves for Polyprotic Acids 872

Amino Acids as Biological Polyprotic Acids 873

19.4 Equilibria of Slightly Soluble Ionic Compounds 874

The Solubility-Product Constant (K_{sp}) 874
Calculations Involving the Solubility-Product Constant 876
Effect of a Common Ion on Solubility 879
Effect of pH on Solubility 880
Applying Ionic Equilibria to the Formation of a Limestone Cave 881
Predicting the Formation of a Precipitate: Q_{sp} Versus K_{sp} 882
Separating Ions by Selective Precipitation and Simultaneous Equilibria 884

CHEMICAL CONNECTIONS TO ENVIRONMENTAL SCIENCE:
THE ACID-RAIN PROBLEM 886

19.5 Equilibria Involving Complex Ions 888

Formation of Complex Ions 888
Complex Ions and the Solubility of Precipitates 889
Complex Ions of Amphoteric Hydroxides 891

CHAPTER REVIEW GUIDE 893

PROBLEMS 898

Chapter 20 | Thermodynamics: Entropy, Free Energy, and Reaction Direction 906

20.1 The Second Law of Thermodynamics: Predicting Spontaneous Change 907

The First Law of Thermodynamics Does Not Predict Spontaneous Change 908
The Sign of ΔH Does Not Predict Spontaneous Change 908
Freedom of Particle Motion and Dispersal of Kinetic Energy 909
Entropy and the Number of Microstates 910
Entropy and the Second Law of Thermodynamics 913
Standard Molar Entropies and the Third Law 913
Predicting Relative S° of a System 914

20.2 Calculating the Change in Entropy of a Reaction 918

Entropy Changes in the System: Standard Entropy of Reaction (ΔS°_{rxn}) 918
Entropy Changes in the Surroundings: The Other Part of the Total 920
The Entropy Change and the Equilibrium State 922
Spontaneous Exothermic and Endothermic Changes 922

20.3 Entropy, Free Energy, and Work 923

Free Energy Change and Reaction Spontaneity 923
Calculating Standard Free Energy Changes 924

The Free Energy Change and the Work a System Can Do 926
The Effect of Temperature on Reaction Spontaneity 927
Coupling of Reactions to Drive a Nonspontaneous Change 931

CHEMICAL CONNECTIONS TO BIOLOGICAL ENERGETICS:
THE UNIVERSAL ROLE OF ATP 932

20.4 Free Energy, Equilibrium, and Reaction Direction 933

CHAPTER REVIEW GUIDE 940

PROBLEMS 944

Monty Rakusen/Cultura/Getty Images

Chapter 21 | Electrochemistry: Chemical Change and Electrical Work 950

21.1 Oxidation-Reduction Reactions 951

A Quick Review of Oxidation-Reduction Concepts 952

Half-Reaction Method for Balancing Redox Reactions 952

21.2 Voltaic Cells: Using Spontaneous Reactions to Generate Electrical Energy 956

Construction and Operation of a Voltaic Cell 956

Notation for a Voltaic Cell 959

Why Does a Voltaic Cell Work? 960

21.3 Cell Potential: Output of a Voltaic Cell 961

Standard Cell Potential (E°_{cell}) 961

Relative Strengths of Oxidizing and Reducing Agents 965

Using $E^\circ_{\text{half-cell}}$ Values to Write Spontaneous Redox Reactions 966

Explaining the Activity Series of the Metals 969

21.4 Free Energy and Electrical Work 970

Standard Cell Potential and the Equilibrium Constant 970

The Effect of Concentration on Cell Potential 972

Following Changes in Potential During Cell Operation 974

Concentration Cells 975

21.5 Electrochemical Processes in Batteries 978

Primary (Nonrechargeable) Batteries 979

Secondary (Rechargeable) Batteries 980

Fuel Cells 981

21.6 Corrosion: An Environmental Voltaic Cell 982

The Corrosion of Iron 982

Protecting Against the Corrosion of Iron 983

21.7 Electrolytic Cells: Using Electrical Energy to Drive Nonspontaneous Reactions 984

Construction and Operation of an Electrolytic Cell 985

Predicting the Products of Electrolysis 986

Stoichiometry of Electrolysis: The Relation Between Amounts of Charge and Products 990

CHEMICAL CONNECTIONS TO BIOLOGICAL ENERGETICS: CELLULAR ELECTROCHEMISTRY AND THE PRODUCTION OF ATP 993

CHAPTER REVIEW GUIDE 994

PROBLEMS 999

Chapter 22 | The Elements in Nature and Industry 1008

22.1 How the Elements Occur in Nature 1009

Earth's Structure and the Abundance of the Elements 1009

Sources of the Elements 1011

22.2 The Cycling of Elements Through the Environment 1013

The Carbon Cycle 1013

The Nitrogen Cycle 1014

The Phosphorus Cycle 1016

22.3 Metallurgy: Extracting a Metal from Its Ore 1019

Pretreating the Ore 1019

Converting Mineral to Element 1020

Refining and Alloying the Element 1022

22.4 Tapping the Crust: Isolation and Uses of Selected Elements 1024

Producing the Alkali Metals: Sodium and Potassium 1024

The Indispensable Three: Iron, Copper, and Aluminum 1025

Mining the Sea for Magnesium 1031

The Sources and Uses of

Hydrogen 1032

22.5 Chemical Manufacturing: Two Case Studies 1035

Sulfuric Acid, the Most Important Chemical 1035

The Chlor-Alkali Process 1037

Chapter 23 | Transition Elements and Their Coordination Compounds 1046

23.1 Properties of the Transition Elements 1047

Electron Configurations of the Transition Metals and Their Ions 1048
Atomic and Physical Properties of the Transition Elements 1050
Chemical Properties of the Transition Elements 1052

23.2 The Inner Transition Elements 1054

The Lanthanides 1054
The Actinides 1055

23.3 Coordination Compounds 1056

Complex Ions: Coordination Numbers, Geometries, and Ligands 1057
Formulas and Names of Coordination Compounds 1058
Isomerism in Coordination Compounds 1062

23.4 Theoretical Basis for the Bonding and Properties of Complex Ions 1065

Applying Valence Bond Theory to Complex Ions 1065
Crystal Field Theory 1067

CHEMICAL CONNECTIONS TO NUTRITIONAL SCIENCE: TRANSITION METALS AS ESSENTIAL DIETARY TRACE ELEMENTS 1074

CHAPTER REVIEW GUIDE 1076

PROBLEMS 1079

Chapter 24 | Nuclear Reactions and Their Applications 1084

24.1 Radioactive Decay and Nuclear Stability 1085

Comparing Chemical and Nuclear Change 1086
The Components of the Nucleus: Terms and Notation 1086
The Discovery of Radioactivity and the Types of Emissions 1087
Modes of Radioactive Decay; Balancing Nuclear Equations 1087
Nuclear Stability and the Mode of Decay 1091

24.2 The Kinetics of Radioactive Decay 1095

Detection and Measurement of Radioactivity 1095
The Rate of Radioactive Decay 1096
Radioisotopic Dating 1099

24.3 Nuclear Transmutation: Induced Changes in Nuclei 1101

Early Transmutation Experiments; Nuclear Shorthand Notation 1102
Particle Accelerators and the Transuranium Elements 1102

24.4 Ionization: Effects of Nuclear Radiation on Matter 1105

Effects of Ionizing Radiation on Living Tissue 1105
Background Sources of Ionizing Radiation 1107
Assessing the Risk from Ionizing Radiation 1108

24.5 Applications of Radioisotopes 1109

Radioactive Tracers 1109
Additional Applications of Ionizing Radiation 1111

24.6 The Interconversion of Mass and Energy 1112

The Mass Difference Between a Nucleus and Its Nucleons 1113
Nuclear Binding Energy and Binding Energy per Nucleon 1114

24.7 Applications of Fission and Fusion 1116

The Process of Nuclear Fission 1116
The Promise of Nuclear Fusion 1120

CHEMICAL CONNECTIONS TO COSMOLOGY: ORIGIN OF THE ELEMENTS IN THE STARS 1121

PROBLEMS 1126

Appendix A Common Mathematical Operations in Chemistry A-1

Appendix B Standard Thermodynamic Values for Selected Substances A-5

Appendix C Equilibrium Constants for Selected Substances A-8

Appendix D Standard Electrode (Half-Cell) Potentials A-14

Appendix E Answers to Selected Problems A-15

Glossary G-1

Index I-1

Data Tables D-1

LIST OF SAMPLE PROBLEMS (Molecular-scene problems are shown in color.)**Chapter 1**

- 1.1 Visualizing Change on the Atomic Scale 5
- 1.2 Distinguishing Between Physical and Chemical Change 7
- 1.3 Converting Units of Temperature 17
- 1.4 Determining the Number of Significant Figures 18
- 1.5 Significant Figures and Rounding 21
- 1.6 Converting Units of Length 25
- 1.7 Converting Units of Volume 26
- 1.8 Converting Units of Mass 27
- 1.9 Converting Units Raised to a Power 28
- 1.10 Calculating Density from Mass and Volume 29

Chapter 2

- 2.1 Distinguishing Elements, Compounds, and Mixtures at the Atomic Scale 45
- 2.2 Calculating the Mass of an Element in a Compound 49
- 2.3 Visualizing the Mass Laws 51
- 2.4 Determining the Numbers of Subatomic Particles in the Isotopes of an Element 57
- 2.5 Calculating the Atomic Mass of an Element 59
- 2.6 Identifying an Element from Its Z Value 63
- 2.7 Predicting the Ion an Element Forms 66
- 2.8 Determining Names and Formulas of Binary Ionic Compounds of Elements That Form One Ion 69
- 2.9 Determining Names and Formulas of Ionic Compounds of Metals That Form More Than One Ion 70
- 2.10 Determining Names and Formulas of Ionic Compounds Containing Polyatomic Ions (Including Hydrates) 72
- 2.11 Recognizing Incorrect Names and Formulas of Ionic Compounds 72
- 2.12 Determining Names and Formulas of Anions and Acids 73
- 2.13 Determining Names and Formulas of Binary Covalent Compounds 74
- 2.14 Recognizing Incorrect Names and Formulas of Binary Covalent Compounds 74
- 2.15 Calculating the Molecular Mass of a Compound 76
- 2.16 Using Molecular Depictions to Determine Formula, Name, and Mass 77

Chapter 3

- 3.1 Converting Between Mass and Amount of an Element 96
- 3.2 Converting Between Number of Entities and Amount of an Element 97
- 3.3 Converting Between Number of Entities and Mass of an Element 97
- 3.4 Converting Between Number of Entities and Mass of a Compound 98
- 3.5 Calculating the Mass Percent of Each Element in a Compound from the Formula 100
- 3.6 Calculating the Mass of an Element in a Compound 101
- 3.7 Determining an Empirical Formula from Masses of Elements 103
- 3.8 Determining a Molecular Formula from Elemental Analysis and Molar Mass 104
- 3.9 Determining a Molecular Formula from Combustion Analysis 106
- 3.10 Balancing a Chemical Equation 110
- 3.11 Writing a Balanced Equation from a Molecular Scene 112
- 3.12 Calculating Quantities of Reactants and Products: Amount (mol) to Amount (mol) and to Mass (g) 114

- 3.13 Calculating Quantities of Reactants and Products: Mass to Mass 116
- 3.14 Using Molecular Depictions in a Limiting-Reactant Problem 118
- 3.15 Calculating Quantities in a Limiting-Reactant Problem: Amount to Amount 119
- 3.16 Calculating Quantities in a Limiting-Reactant Problem: Mass to Mass 120
- 3.17 Calculating Percent Yield 123

Chapter 4

- 4.1 Calculating the Molarity of a Solution 142
- 4.2 Calculating Mass of Solute in a Given Volume of Solution 143
- 4.3 Preparing a Dilute Solution from a Concentrated Solution 145
- 4.4 Visualizing Changes in Concentration 146
- 4.5 Using Molecular Scenes to Depict an Ionic Compound in Aqueous Solution 149
- 4.6 Determining Amount (mol) of Ions in Solution 150
- 4.7 Predicting Whether a Precipitation Reaction Occurs; Writing Ionic Equations 155
- 4.8 Using Molecular Depictions in Precipitation Reactions 156
- 4.9 Calculating Amounts of Reactants and Products in a Precipitation Reaction 158
- 4.10 Solving a Limiting-Reactant Problem for a Precipitation Reaction 159
- 4.11 Determining the Number of H^+ (or OH^-) Ions in Solution 162
- 4.12 Writing Ionic Equations for Acid-Base Reactions 165
- 4.13 Calculating the Amounts of Reactants and Products in an Acid-Base Reaction 166
- 4.14 Finding the Concentration of an Acid from a Titration 168
- 4.15 Determining the Oxidation Number of Each Element in a Compound (or Ion) 171
- 4.16 Identifying Redox Reactions and Oxidizing and Reducing Agents 172
- 4.17 Finding the Amount of Reducing Agent by Titration 174
- 4.18 Identifying the Type of Redox Reaction 182

Chapter 5

- 5.1 Converting Units of Pressure 206
- 5.2 Applying the Volume-Pressure Relationship 213
- 5.3 Applying the Volume-Temperature and Pressure-Temperature Relationships 214
- 5.4 Applying the Volume-Amount and Pressure-Amount Relationships 214
- 5.5 Applying the Volume-Pressure-Temperature Relationship 215
- 5.6 Solving for an Unknown Gas Variable at Fixed Conditions 216
- 5.7 Using Gas Laws to Determine a Balanced Equation 217
- 5.8 Calculating Gas Density 219
- 5.9 Finding the Molar Mass of a Volatile Liquid 221
- 5.10 Applying Dalton's Law of Partial Pressures 222
- 5.11 Calculating the Amount of Gas Collected over Water 224
- 5.12 Using Gas Variables to Find Amounts of Reactants or Products I 225
- 5.13 Using Gas Variables to Find Amounts of Reactants or Products II 226
- 5.14 Applying Graham's Law of Effusion 233

Chapter 6

- 6.1 Determining the Change in Internal Energy of a System 258
- 6.2 Calculating Pressure-Volume Work Done by or on a System 260
- 6.3 Drawing Enthalpy Diagrams and Determining the Sign of ΔH 263
- 6.4 Relating Quantity of Heat and Temperature Change 265
- 6.5 Determining the Specific Heat Capacity of a Solid 266
- 6.6 Determining the Enthalpy Change of an Aqueous Reaction 267
- 6.7 Calculating the Heat of a Combustion Reaction 270
- 6.8 Using a Thermochemical Equation to Convert Between Amount of Substance and Heat 271
- 6.9 Using Hess's Law to Calculate an Unknown ΔH 273
- 6.10 Writing Formation Equations 276
- 6.11 Calculating $\Delta H_{\text{rxn}}^\circ$ from ΔH_f° Values 277

Chapter 7

- 7.1 Interconverting Wavelength and Frequency 293
- 7.2 Interconverting Energy, Wavelength, and Frequency 297
- 7.3 Determining ΔE and λ of an Electron Transition 302
- 7.4 Calculating the de Broglie Wavelength of an Electron 307
- 7.5 Applying the Uncertainty Principle 309
- 7.6 Determining Quantum Numbers for an Energy Level 313
- 7.7 Determining Sublevel Names and Orbital Quantum Numbers 314
- 7.8 Identifying Incorrect Quantum Numbers 314

Chapter 8

- 8.1 Determining Electron Configurations 338
- 8.2 Ranking Elements by Atomic Size 342
- 8.3 Ranking Elements by First Ionization Energy 344
- 8.4 Identifying an Element from Its Ionization Energies 346
- 8.5 Writing Electron Configurations of Main-Group Ions 350
- 8.6 Writing Electron Configurations and Predicting Magnetic Behavior of Transition Metal Ions 352
- 8.7 Ranking Ions by Size 354

Chapter 9

- 9.1 Depicting Ion Formation 367
- 9.2 Predicting Relative Lattice Energy from Ionic Properties 371
- 9.3 Comparing Bond Length and Bond Strength 376
- 9.4 Using Bond Energies to Calculate $\Delta H_{\text{rxn}}^\circ$ 382
- 9.5 Determining Bond Polarity from EN Values 387

Chapter 10

- 10.1 Writing Lewis Structures for Species with Single Bonds and One Central Atom 401
- 10.2 Writing Lewis Structures for Molecules with Single Bonds and More Than One Central Atom 402
- 10.3 Writing Lewis Structures for Molecules with Multiple Bonds 403
- 10.4 Writing Resonance Structures and Assigning Formal Charges 407
- 10.5 Writing Lewis Structures for Octet-Rule Exceptions 411
- 10.6 Examining Shapes with Two, Three, or Four Electron Groups 420
- 10.7 Examining Shapes with Five or Six Electron Groups 421
- 10.8 Predicting Molecular Shapes with More Than One Central Atom 422
- 10.9 Predicting the Polarity of Molecules 424

Chapter 11

- 11.1 Postulating Hybrid Orbitals in a Molecule 444
- 11.2 Describing the Types of Orbitals and Bonds in Molecules 448

- 11.3 Predicting Stability of Species Using MO Diagrams 452
- 11.4 Using MO Theory to Explain Bond Properties 455

Chapter 12

- 12.1 Drawing Hydrogen Bonds Between Molecules of a Substance 471
- 12.2 Identifying the Types of Intermolecular Forces 473
- 12.3 Finding the Heat of a Phase Change Depicted by Molecular Scenes 480
- 12.4 Applying the Clausius-Clapeyron Equation 484
- 12.5 Using a Phase Diagram to Predict Phase Changes 487
- 12.6 Determining the Number of Particles per Unit Cell and the Coordination Number 495
- 12.7 Determining Atomic Radius 498
- 12.8 Determining Atomic Radius from the Unit Cell 499

Chapter 13

- 13.1 Predicting Relative Solubilities 535
- 13.2 Calculating an Aqueous Ionic Heat of Solution 541
- 13.3 Using Henry's Law to Calculate Gas Solubility 547
- 13.4 Calculating Molality 548
- 13.5 Expressing Concentrations in Parts by Mass, Parts by Volume, and Mole Fraction 550
- 13.6 Interconverting Concentration Terms 551
- 13.7 Using Raoult's Law to Find Vapor Pressure 553
- 13.8 Determining Boiling and Freezing Points of a Solution 556
- 13.9 Determining Molar Mass from Colligative Properties 558
- 13.10 Depicting Strong Electrolyte Solutions 560

Chapter 15

- 15.1 Drawing Hydrocarbons 631
- 15.2 Naming Hydrocarbons and Understanding Chirality and Geometric Isomerism 640

- 24.7 Writing Equations for Transmutation Reactions 1104
- 24.8 Calculating the Binding Energy per Nucleon 1114

ABOUT THE AUTHORS

Courtesy of Ruth Melnick

Martin S. Silberberg received a B.S. in Chemistry from the City University of New York and a Ph.D. in Chemistry from the University of Oklahoma. He then worked as a research associate in analytical biochemistry at the Albert Einstein College of Medicine in New York City, where he studied the molecular nature of Parkinson's disease and other neurological disorders. Following his years in research, Dr. Silberberg joined the faculty of Bard College at Simon's Rock, a liberal arts college known for its excellence in teaching small classes of highly motivated students. As head of the Natural Sciences Major and Director of Premedical Studies, he taught courses in general chemistry, organic chemistry, biochemistry, and liberal-arts chemistry. The close student contact afforded insights into strategies that help students understand chemistry, which he then applied by establishing a textbook writing, editing, and consulting company. Before writing his own texts, he worked as a content and development editor on chemistry, biochemistry, and physics texts for several major academic publishers. He resides with his wife near Amherst, Massachusetts, where he enjoys the rich cultural and academic life of the area and relaxes by nature walking, baking, and singing.

Courtesy of Ralph L. Amateis

Patricia G. Amateis graduated with a B.S. in Chemistry Education from Concord University in West Virginia and a Ph.D. in Analytical Chemistry from Virginia Tech. She was on the faculty of the Chemistry Department at Virginia Tech for 38 years, until her retirement in September 2022. She taught General Chemistry and Analytical Chemistry and served as the Director of General Chemistry and as the Director of Undergraduate Programs. She taught thousands of students during her career and was awarded the University Sporn Award for Introductory Teaching, the Alumni Teaching Award, the Jimmy W. Viers Teaching Award, and the William E. Wine Award for a history of university teaching excellence. She and her husband live in Blacksburg, Virginia, and are the parents of three adult children and the proud grandparents of a grandson. In her free time, she enjoys biking, hiking, swimming, and playing the double second in Panjammers, Blacksburg's steel drum band.

PREFACE

Chemistry is so crucial to an understanding of medicine and biology, environmental science, and many areas of engineering and industrial processing that it has become a requirement for an increasing number of academic majors. Furthermore, chemical principles lie at the core of some of the key societal issues we face in the 21st century—dealing with climate change, finding new energy options, and supplying nutrition and curing disease on an ever more populated planet.

SETTING THE STANDARD FOR A CHEMISTRY TEXT

The tenth edition of *Chemistry: The Molecular Nature of Matter and Change* maintains its standard-setting position among general chemistry textbooks by evolving further to meet the needs of professor and student. The text still contains the most accurate molecular illustrations, consistent step-by-step worked problems, and an extensive collection of end-of-chapter problems. And changes throughout this edition make the text more readable and succinct, the artwork more teachable and modern, and the design more focused and inviting. The three hallmarks that have made this text a market leader are now demonstrated in its pages more clearly than ever.

Visualizing Chemical Models—Macroscopic to Molecular

Chemistry deals with observable changes caused by unobservable atomic-scale events, requiring an appreciation of a size gap of mind-boggling proportions. One of the text's goals coincides with that of so many instructors: to help students visualize chemical events on the molecular scale. Thus, concepts are explained first at the macroscopic level and then from a molecular point of view, with pedagogic illustrations always placed next to the discussions to bring the point home for today's visually oriented students.

Thinking Logically to Solve Problems

The problem-solving approach, based on the four-step method widely accepted by experts in chemical education, is introduced in Chapter 1 and employed *consistently* throughout the text. It encourages students to *plan* a logical approach to a problem, and only then proceed to *solve* it. Each sample problem includes a *check*, which fosters the habit of “thinking through” both the chemical and the quantitative reasonableness of the answer. Finally, for *practice* and reinforcement, each sample problem is followed immediately by *two* similar follow-up problems. And *Chemistry* marries problem solving to visualizing models with molecular-scene problems, which appear not only in homework sets, as in other texts, but also in the running text, where they are worked out stepwise.

Road Map

SAMPLE PROBLEM 5.3 Applying the Volume-Temperature and Pressure-Temperature Relationships

Problem A balloon is filled with 1.95 L of air at 25°C and then placed in a car sitting in the sun. What is the volume of the balloon when the temperature in the car reaches 90°C?

Plan We know the initial volume (V_1) and the initial (T_1) and final (T_2) temperatures of the gas; we must find the final volume (V_2). The pressure of the gas is fixed, since the balloon is subjected to atmospheric pressure, and n is fixed, since air cannot escape or enter the balloon. We convert both T values to kelvins, rearrange the ideal gas law, and solve for V_2 (see the road map).

Solution Summarizing the gas variables:

$$\begin{array}{ll} V_1 = 1.95 \text{ L} & V_2 = \text{unknown} \\ T_1 = 25^\circ\text{C} \text{ (convert to K)} & T_2 = 90^\circ\text{C} \text{ (convert to K)} \\ P \text{ and } n \text{ remain constant} & \end{array}$$

Converting T from $^\circ\text{C}$ to K:

$$T_1 (\text{K}) = 25^\circ\text{C} + 273.15 = 298 \text{ K} \quad T_2 (\text{K}) = 90^\circ\text{C} + 273.15 = 363 \text{ K}$$

Rearranging the ideal gas law and solving for V_2 : at fixed n and P , we have

$$\frac{P_1 V_1}{n_1 T_1} = \frac{P_2 V_2}{n_2 T_2} \quad \text{or} \quad \frac{V_1}{T_1} = \frac{V_2}{T_2}$$

$$V_2 = V_1 \times \frac{T_2}{T_1} = 1.95 \text{ L} \times \frac{363 \text{ K}}{298 \text{ K}} = 2.38 \text{ L}$$

Check Let's predict the change to check the math: because $T_2 > T_1$, we expect $V_2 > V_1$. Thus, the temperature ratio should be greater than 1 (T_2 in the numerator). The T ratio is about 1.2 ($363/298$), so the V ratio should also be about 1.2 ($2.38/1.95 \approx 1.2$).

FOLLOW-UP PROBLEMS

5.3A A steel tank used for fuel delivery is fitted with a safety valve that opens if the internal pressure exceeds 1.00×10^3 torr. The tank is filled with methane at 23°C and 0.991 atm and placed in boiling water at 100°C . What is the pressure in the heated tank? Will the safety valve open?

5.3B A sample of nitrogen occupies a volume of 32.5 L at 40°C . Assuming that the pressure remains constant, what temperature (in $^\circ\text{C}$) will result in a decrease in the sample's volume to 28.6 L?

SOME SIMILAR PROBLEMS 5.26–5.29

SAMPLE PROBLEM 2.3 Visualizing the Mass Laws

Problem The scenes below represent an atomic-scale view of a chemical reaction:

Which of the mass laws—mass conservation, definite composition, and/or multiple proportions—is (are) illustrated?

Plan From the depictions, we note the numbers, colors, and combinations of atoms (spheres) to see which mass laws pertain. If the numbers of each atom are the same before and after the reaction, the total mass did not change (mass conservation). If a compound forms that always has the same atom ratio, the elements are present in fixed parts by mass (definite composition). If the same elements form different compounds and the ratio of the atoms of one element that combine with one atom of the other element is a small whole number, the ratio of their masses is a small whole number as well (multiple proportions).

Solution There are seven purple and nine green atoms in each circle, so mass is conserved. The compound formed has one purple and two green atoms, so it has definite composition. Only one compound forms, so the law of multiple proportions does not pertain.

FOLLOW-UP PROBLEMS

2.3A The following scenes represent a chemical change. Which of the mass laws is (are) illustrated?

2.3B Which sample(s) best display(s) the fact that compounds of bromine (orange) and fluorine (yellow) exhibit the law of multiple proportions? Explain.

SOME SIMILAR PROBLEMS 2.22 and 2.23

SAMPLE PROBLEM 5.4 Applying the Volume-Amount and Pressure-Amount Relationships

Problem A scale model of a blimp rises when it is filled with helium to a volume of 55.0 dm^3 . When 1.10 mol of He is added to the blimp, the volume is 26.2 dm^3 . How many more grams of He must be added to make it rise? Assume constant T and P .

Plan We are given the initial amount of helium (n_1), the initial volume of the blimp (V_1), and the volume needed for it to rise (V_2), and we need the additional mass of helium to make it rise. So, we first need to find n_2 . We rearrange the ideal gas law to the appropriate form, solve for n_2 , subtract n_1 to find the additional amount (n_{add}), and then convert moles to grams (see the road map).

Applying Ideas to the Real World

As the most practical science, chemistry should have a textbook that highlights its countless applications. Moreover, today's students may enter emerging chemistry-related hybrid fields, like biomaterials science or planetary geochemistry, and the text they use should point out the relevance of chemical concepts to such related sciences. The *Chemical Connections* and *Tools of the Laboratory* boxed essays (which include problems for added relevance), the more pedagogic margin notes, and the many applications woven into the chapter content are up-to-date, student-friendly features that are directly related to the neighboring content.

CHEMICAL CONNECTIONS TO ENVIRONMENTAL ENGINEERING

Most water destined for human use comes from lakes, rivers, reservoirs, or groundwater. Present in this essential resource may be soluble toxic organic compounds and high concentrations of NO_3^- and Fe^{3+} , colloidal clay and microbes, and suspended debris. Let's see how water is treated to remove these dissolved, dispersed, and suspended particles.

Water Treatment Plants

Treating water involves several steps (Figure B13.1):

Step 1. Screening and settling. As water enters the facility, screens remove debris, and settling removes sand and other particles.

Step 2. Coagulating. This step and the next two remove colloids. These particles have negative surfaces that repel each other. Added aluminum sulfate [cake alum; $\text{Al}_2(\text{SO}_4)_3$] or iron(III) chloride (FeCl_3), which supply Al^{3+} or Fe^{3+} ions that neutralize the charges, coagulates the particles through intermolecular forces.

Step 3. Flocculating and sedimenting. Mixing water and flocculating agents in large basins causes a fluffy *floc* to form. Added cationic polymers form long-chain bridges between floc particles, which grow bigger and flow into other basins, where they form a sediment and are removed. Some plants use *dissolved air flotation* (DAF) instead: bubbles forced through the water attach to the floc, and the floating mass is skimmed.

Step 4. Filtering. Various filters remove remaining particles. In *slow sand filters*, the water passes through sand and/or gravel of increasing particle size. In *rapid sand filters*, the sand is backwashed with water, and the colloidal mass is removed. Membrane filters (not shown) with pore sizes of 0.1–10 μm are thin tubes.

Solutions and Colloids in Water Purification

Step 5. Disinfecting. Water sources often contain harmful microorganisms that are killed by one of three agents:

- Chlorine, as aqueous bleach (ClO^-) or Cl_2 , is most common, but carcinogenic chlorinated organic compounds can form.
- UV light emitted by high-intensity fluorescent tubes disinfects by disrupting microorganisms' DNA.
- Ozone (O_3) gas is a powerful oxidizing agent.

Sodium fluoride (NaF) to prevent tooth decay and phosphate salts to prevent leaching of lead from pipes may then be added.

Step 6 (not shown). Adsorbing onto granular activated carbon (GAC). Petroleum and other organic contaminants are removed by adsorption. GAC is a highly porous agent formed by "activating" wood, coal, or coconut shells with steam: 1 kg of GAC has a surface area of 275 acres!

Water Softening via Ion Exchange

Water with large amounts of 2+ ions, such as Ca^{2+} and Mg^{2+} , is called **hard water**. Combined with fatty-acid anions in soap, these cations form solid deposits on clothes, washing machines, and sinks:

When a large amount of HCO_3^- is present, the cations form *scales*, a carbonate deposit in boilers and hot-water pipes that interferes with the transfer of heat:

Figure B13.2 Ion exchange to remove hard-water cations.

anionic groups, such as SO_3^- or COO^- , and Na^+ ions for charge balance (Figure B13.2). The hard-water cations displace the Na^+ ions and bind to the anionic groups. When all resin sites are occupied, the resin is regenerated with concentrated Na^+ solution that exchanges Na^+ ions for bound Ca^{2+} and Mg^{2+} .

Membrane Processes and Reverse Osmosis

Membranes with 0.0001–0.01 μm pores can remove unwanted ions from water. Recall that solutions of different concentrations separated by a semipermeable membrane create osmotic pressure. In **reverse osmosis**, a pressure *greater* than the osmotic pressure is *applied* to the more concentrated solution to force water back through the membrane and filter out ions. In homes, toxic *heavy-metal* ions, such as Pb^{2+} , Cd^{2+} , and Hg^{2+} , are removed this way. On a large scale, reverse osmosis is used for **desalination**, which can convert seawater (40,000 ppm of ions) to drinking water (400 ppm) (Figure B13.3). There are over 18,000 desalination units worldwide, providing water for 300 million people.

Wastewater Treatment

Wastewater, used domestic or industrial water, is treated in several ways before being returned to a natural source:

- In **primary** treatment, the water enters a settling basin to remove particles.
- In **biological** treatment, bacteria metabolize organic compounds and are then removed by settling.
- In **advanced** treatment, a process is tailored to remove a specific pollutant. For example, ammonia, which causes excessive growth of plants and algae, is removed in two steps:

1. **Nitrification.** Certain bacteria oxidize ammonia (electron donor) with O_2 (electron acceptor) to form nitrate ion:

2. **Denitrification.** Other bacteria oxidize an added compound, like methanol (CH_3OH), using the NO_3^- :

Thus, the process converts NH_3 in wastewater to N_2 , which is released to the atmosphere.

Problems

B13.1 Briefly answer each of the following:

- Why is cake alum [$\text{Al}_2(\text{SO}_4)_3$] added during water purification?
- Why is water that contains large amounts of Ca^{2+} and Mg^{2+} difficult to use for cleaning?
- What is the meaning of *reverse* in reverse osmosis?
- Why might a water treatment plant use ozone as a disinfectant instead of chlorine?
- How does passing a saturated NaCl solution through a "spent" ion-exchange resin regenerate the resin?

B13.2 Wastewater discharged into a stream by a sugar refinery contains 3.55 g of sucrose ($\text{C}_{12}\text{H}_{22}\text{O}_{11}$) per liter. A government-sponsored study is testing the feasibility of removing the sugar by reverse osmosis. What pressure must be applied to the wastewater solution at 20 °C to produce pure water?

TOOLS OF THE LABORATORY

Nuclear Magnetic Resonance (NMR) Spectroscopy

In addition to mass spectrometry (Chapter 2) and infrared (IR) spectroscopy (Chapter 9), one of the most useful tools for analyzing organic and biochemical structures is **nuclear magnetic resonance (NMR) spectroscopy**, which measures the molecular environments of certain nuclei in a molecule.

Like electrons, several types of nuclei, such as ^1H , ^{13}C , ^{19}F , ^{31}P , and ^1H , act as if they spin in either of two directions, each of which creates a tiny magnetic field. In this discussion, we focus primarily on ^1H -NMR spectroscopy, which measures changes in the nuclei of the most common isotope of hydrogen. Oriented randomly, the magnetic fields of all the ^1H nuclei in a sample of compound, when placed in a strong external magnetic field (B_0), become aligned either with the external field (parallel) or *against* it (antiparallel). Most nuclei adopt the parallel orientation, which is slightly lower in energy. The energy difference (ΔE) between the two energy states (spin states) lies in the radio-frequency (rf) region of the electromagnetic spectrum (Figure B15.1).

When an ^1H (blue arrow) in the lower energy (parallel) spin state absorbs a photon in the radio-frequency region with an energy equal to ΔE , it "flips," in a process called *resonance*, to the higher energy (antiparallel) spin state. The system then re-emits that energy, which is detected by the rf receiver of the ^1H -NMR spectrometer. The ΔE between the two states depends on the *actual* magnetic field acting on each ^1H nucleus, which is affected by the tiny magnetic fields of the *electrons* of atoms adjacent to that nucleus. Thus, the ΔE required for resonance of each ^1H nucleus depends on its specific molecular environment—the C atoms, electronegative atoms, multiple bonds, and aromatic rings around it. ^1H nuclei in different molecular environments produce different peaks in the ^1H -NMR spectrum.

An ^1H -NMR spectrum, which is unique for each compound, is a series of peaks that represents the resonance as a function of the changing magnetic field. The *chemical shift* of the ^1H nuclei in a given environment is where a peak appears. Chemical shifts are shown relative to that of an added standard, tetramethylsilane [(CH_3) $_4\text{Si}$, or TMS]. TMS has 12 ^1H nuclei bonded to four C atoms that are bonded to one Si atom in a tetrahedral arrangement, so all 12 are in identical environments and produce only one peak.

Figure B15.2 shows the ^1H -NMR spectrum of acetone. The six ^1H nuclei of acetone have identical environments: all six are bonded to two C atoms that are each bonded to the C atom involved in the $\text{C}=\text{O}$ bond. So one peak is produced, but at a different position from the TMS peak. The spectrum of dimethoxymethane in Figure B15.3 shows two peaks in addition to the TMS peak, since the ^1H nuclei have two different environments. The taller peak is due to the six ^1H nuclei in the two CH_3 groups, and the shorter peak is due to the two ^1H nuclei in the CH_2 group. The area under each peak (given as a number of chart-paper grid spaces) is proportional to the *number of ^1H nuclei in a given environment*. Note that the area ratio is 20.3/6.8 $\approx$ 3/1, the same as the ratio of six nuclei in the CH_3 groups to two in the CH_2 group. Thus, by analyzing the chemical shifts and peak areas, the chemist learns the type and number of hydrogen atoms in the compound.

A Purple Mule, Not a Blue Horse and a Red Donkey

A mule is a genetic mix, a hybrid, of a horse and a donkey; it is not a horse one instant and a donkey the next. Similarly, the color purple is a mix of red and blue, not red one instant and blue the next. In the same sense, a resonance hybrid is one molecular species, not one resonance structure this instant and another resonance structure the next. The problem is that we cannot depict the actual species, the hybrid, accurately with a single Lewis structure.

Reinforcing through Review and Practice

A favorite feature, the section summaries that conclude every section restate the major ideas concisely and immediately (rather than postponing such review until the end of the chapter).

A rich catalog of study aids ends each chapter to help students review the content:

- **Learning Objectives**, with section and/or sample problem numbers, focus on the concepts to understand and the skills to master.
- **Key Terms**, boldfaced and defined within the chapter, are listed here by section (with page numbers), as well as being defined in the *Glossary*.
- **Key Equations and Relationships** are highlighted and numbered within the chapter and listed here with page numbers.
- **Chapter Practice Test** is a new feature in the tenth edition. Students can test their knowledge of each chapter's topics with a ten-question multiple-choice practice test. The Practice Test questions thoroughly cover the concepts in each chapter. Answers are provided at the end of the test and complete solutions are available in the electronic textbook.
- **Brief Solutions to Follow-up Problems** triple the number of worked problems by providing multistep calculations at the end of the chapter, rather than just numerical answers at the back of the book.

Summary of Section 9.1

- Nearly all naturally occurring substances consist of atoms or ions bonded to others. Chemical bonding allows atoms to lower their energy.
- Ionic bonding occurs when metal atoms transfer electrons to nonmetal atoms, and the resulting ions attract each other and form an ionic solid.
- Covalent bonding is most common between nonmetal atoms and usually results in individual molecules. Bonded atoms share one or more pairs of electrons that are localized between them.
- Metallic bonding occurs when many metal atoms pool their valence electrons into a delocalized electron "sea" that holds all the atoms in the sample together.
- The Lewis electron-dot symbol of a main-group atom shows valence electrons as dots surrounding the element symbol.
- The octet rule says that, when bonding, many atoms lose, gain, or share electrons to attain a filled outer level of eight (or two) electrons.

CHAPTER REVIEW GUIDE			
Learning Objectives		Relevant section (S) and/or sample problem (SP) numbers appear in parentheses.	
Understand These Concepts		Master These Skills	
1. The defining characteristics of the three types of matter—element, compound, and mixture—on the macroscopic and atomic levels, and of the particles within them—atoms, molecules, and ions (§2.1)		1. Distinguishing elements, compounds, and mixtures at the atomic scale (SP 2.1)	
2. The types of mixtures and their properties (§2.1)		2. Using the mass ratio of element to compound to find the mass of an element in a compound (SP 2.2)	
3. The significance of the three mass laws—mass conservation, definite composition, and multiple proportions (§2.2)		3. Visualizing the mass laws (SP 2.3)	
4. The postulates of Dalton's atomic theory and how it explains the mass laws (§2.2)		4. Determining the numbers of subatomic particles in the isotopes of an element (SP 2.4)	
5. The major contribution of experiments by Thomson, Millikan, and Rutherford to our understanding of atomic structure (§2.3)		5. Calculating an atomic mass from isotopic composition (SP 2.5)	
6. The structure of the atom, the main features of the subatomic particles, and the importance of isotopes in determining atomic mass (§2.4)		6. Identifying an element from its Z value (SP 2.6)	
7. The format of the periodic table and the general location and characteristics of metals, metalloids, and nonmetals (§2.5)		7. Predicting the ion an element forms (SP 2.7)	
8. The essential features of ionic and covalent compounds and the distinction between them (§2.6)		8. Naming and writing the formula of an ionic compound formed from the ions in Tables 2.4–2.6 (SPs 2.8–2.11, 2.16)	
		9. Naming and writing the formula of an acid and its anion (SP 2.12)	
		10. Naming and writing the formula of a binary covalent compound (SPs 2.13, 2.14, 2.16)	
		11. Calculating the molecular or formula mass of a compound (SP 2.15, 2.16)	
Key Terms		Page numbers appear in parentheses.	
anion (64)	covalent compound (64)	ion (64)	monatomic ion (65)
atom (42)	crystallization (44)	ionic compound (64)	neutron (n^0) (55)
atomic mass (59)	distillation (44)	isotopes (57)	nonmetal (62)
atomic mass unit (amu) (58)	electron (e^-) (55)	isotopic mass (59)	nucleus (55)
atomic number (Z) (56)	element (42)	law of definite (or constant) composition (48)	oxygen (71)
atomic symbol (57)	filtration (44)	law of mass conservation (46)	percent by mass (mass percent, mass %) (47)
binary covalent compound (74)	formula mass (76)	law of multiple proportions (49)	period (61)
binary ionic compound (64)	fraction by mass (mass fraction) (47)	mass number (A) (56)	periodic table of the elements (61)
cathode ray (52)	group (61)	mass spectrometry (58)	polyatomic ion (67)
cation (64)	heterogeneous mixture (43)	metal (62)	proton (p^+) (55)
chemical bond (64)	homogeneous mixture (solution) (43)	metalloid (semimetal) (62)	substance (41)
chemical formula (68)	hydrate (71)	molecular mass (76)	volatility (44)
chromatography (44)		mixture (41)	
compound (42)		molecule (42)	
covalent bond (66)			
Key Equations and Relationships		Page numbers appear in parentheses.	
21 Finding the mass of an element in a given mass of compound (48):		23 Calculating the average atomic mass of the isotopes of an element (59):	
Mass of element in sample = mass of compound in sample		Atomic mass = $\sum(\text{isotopic mass})(\text{fractional abundance of isotope})$	
$\times \frac{\text{mass of element in compound}}{\text{mass of compound}}$		24 Determining the molecular mass of a formula unit of a compound (76):	
		Molecular mass or formula mass = sum of atomic masses	
22 Calculating the number of neutrons in an atom (57):			
Number of neutrons = mass number – atomic number			
or,			
$N = A - Z$			

CHAPTER PRACTICE TEST

The answers to the Practice Test problems are shown below and the full solutions can be found in the e-book.

1. Which of the following two statements are *not* correct? Select both answers.

- (a) The atomic number gives the number of electrons in a neutral atom.
 (b) SrF_2 is an ionic compound.
 (c) Group 16 nonmetals have a charge of 2– in binary ionic compounds.
 (d) The inner transition elements are all metals.
 (e) In the compound carbon tetrachloride, carbon forms ions with a 4+ charge.

(f) Mixtures and compounds can be separated into their pure component substances by physical means.

2. How many protons, neutrons, and electrons does $^{90}\text{Zr}^{2+}$ have?

- (a) 50 protons, 40 neutrons, and 47 electrons
 (b) 40 protons, 50 neutrons, and 40 electrons
 (c) 50 protons, 50 neutrons, and 53 electrons
 (d) 40 protons, 50 neutrons, and 43 electrons
 (e) 40 protons, 50 neutrons, and 37 electrons

3. What is the formula of cobalt(III) sulfite?

- (a) CoSO_4 (b) Co_2S_3 (c) $\text{Co}_2(\text{SO}_3)_3$
 (d) $\text{Co}_2(\text{SO}_4)_3$ (e) $\text{Co}_2(\text{SO}_3)_2$ (f) Co_2S_3

4. A metallic element forms an ionic compound with bromine, having the formula XBr_2 . This ion of element X has 70 electrons. What is the identity of the element?

- (a) Yb (b) Hf (c) Pb (d) Ho (e) W

5. Which is the correct formula for the compound formed between the 6th period alkali metal and the hypobromite ion?

- (a) RbBrO_2 (b) $\text{Sr}(\text{BrO}_2)_2$ (c) CsBrO_2
 (d) RbBrO (e) $\text{Ba}(\text{BrO}_2)_2$ (f) CsBrO

6. Two of the following compounds are incorrectly named. Select **both** compounds that are incorrectly named.

- (a) CuF_2 copper(II) fluoride
 (b) As_2O_5 tetraarsenic hexoxide
 (c) AlCl_3 aluminum chloride
 (d) K_3PO_4 potassium phosphide
 (e) H_2SO_3 sulfurous acid

7. A compound is composed of carbon, hydrogen, and oxygen. If a sample of the compound has a mass of 171.2 g and the compound is 42.1% carbon and 51.4% oxygen, what is the mass of hydrogen in the sample?

- (a) 6.50 g (b) 11.1 g (c) 18.7 g
 (d) 21.4 g (e) 26.3 g

8. Calcium has five stable isotopes: ^{40}Ca (39.96 amu), ^{42}Ca (41.96 amu), ^{44}Ca (42.96 amu), ^{46}Ca (43.96 amu), and ^{48}Ca (45.96 amu). Which one of these isotopes is the most abundant?

- (a) ^{40}Ca (b) ^{42}Ca (c) ^{44}Ca (d) ^{46}Ca (e) ^{48}Ca

9. The element antimony has two naturally occurring isotopes: ^{121}Sb and ^{123}Sb . Given that the isotopic masses of these two isotopes are 120.9038 amu and 122.9042 amu, respectively, and the average atomic mass of antimony is 121.76 amu, calculate the percent abundance of ^{121}Sb .

- (a) 42.80% (b) 57.20% (c) 32.12% (d) 66.54% (e) 61.42%

10. A sample of a compound contains 2.04 kg of aluminum and 1.81 kg of oxygen. What mass of aluminum is in a 7.11 kg sample of the compound?

- (a) 3.56 kg (b) 3.14 kg (c) 3.77 kg
 (d) 4.11 kg (e) 5.02 kg

Answers: 1. e, f; 2. e; 3. c; 4. e; 5. f; 6. c, d; 7. b; 8. a; 9. b; 10. c

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

2.1A (a) There is only one type of atom (blue) present, so this is an element. (b) Two different atoms (orange and green) appear in a fixed ratio of 1/1, so this is a compound. (c) These molecules consist of one type of atom (orange), so this is an element.

2.1B There are two types of particles reacting (left circle), one with two blue atoms and the other with two orange; the depiction shows a mixture of two elements. In the product (right circle), all the particles have one blue atom and one orange; this is a compound.

2.2A Mass (g) of fool's gold

$$= 86.2 \text{ g fool's gold} \times \frac{110.0 \text{ g fool's gold}}{51.2 \text{ g fool's gold}}$$

$$= 185 \text{ g fool's gold}$$

Mass (g) of sulfur = 185 g fool's gold – 86.2 g iron

$$= 98.8 \text{ g sulfur}$$

2.2B Mass (g) of silver

$$= 3.57 \text{ g silver-bromide} \times \frac{15.4 \text{ g silver}}{26.8 \text{ g silver-bromide}}$$

$$= 2.05 \text{ g silver}$$

Mass (g) of bromine = 3.57 g silver bromide – 2.05 g silver

$$= 1.52 \text{ g bromine}$$

2.3A There are 12 black atoms and 14 red atoms in each circle (mass conservation). In the right circle, there are molecules of two compounds—one compound has one black and one red atom, and the other has one black and two red atoms (multiple proportions). Each compound has a fixed ratio of black-to-red atoms (definite composition).

2.3B Sample B. Two bromine-fluorine compounds appear. In one, there are three fluorine atoms for each bromine; in the other, there is one fluorine for each bromine. Therefore, the masses of fluorine that combine with a given mass of bromine are in a 3/1 ratio.

Finally, an exceptionally large number of qualitative, quantitative, and molecular-scene problems end each chapter. Four types of problems are presented—three by chapter section, with comprehensive problems following:

- **Concept Review Questions** test qualitative understanding of key ideas.
- **Skill-Building Exercises** are grouped in similar pairs, with one of each pair answered in the back of the book. A group of similar exercises may begin with explicit steps and increase in difficulty, gradually weaning the student from the need for multistep directions.
- **Problems in Context** apply the skills learned in the skill-building exercises to interesting scenarios, including realistic examples dealing with industry, medicine, and the environment.
- **Comprehensive Problems**, mostly based on realistic applications, are more challenging and rely on material from any section of the current chapter or any previous chapter.

PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

Depicting Molecules and Ions with Lewis Structures (Sample Problems 10.1 to 10.5)

Concept Review Questions

10.1 Which of these atoms *cannot* serve as a central atom in a Lewis structure: (a) O; (b) He; (c) F; (d) H; (e) P? Explain.

10.2 When is a resonance hybrid needed to adequately depict the bonding in a molecule? Using NO_2 as an example, explain how a resonance hybrid is consistent with the actual bond length, bond strength, and bond order.

10.3 In which of these structures does X obey the octet rule?

10.4 What is required for an atom to expand its valence shell? Which of the following atoms can expand its valence shell: F, S, H, Al, Se, Cl?

Skill-Building Exercises (grouped in similar pairs)

10.5 Draw a Lewis structure for (a) SiF_4 ; (b) SeCl_2 ; (c) COF_2 (C is the central atom).

10.6 Draw a Lewis structure for (a) PH_4^+ ; (b) C_2F_4 ; (c) SbH_3 .

10.7 Draw a Lewis structure for (a) PF_3 ; (b) H_2CO_3 (both H atoms are attached to O atoms); (c) CS_2 .

10.8 Draw a Lewis structure for (a) CH_3S ; (b) S_2Cl_2 ; (c) CHCl_3 .

10.9 Draw Lewis structures of all the important resonance forms of (a) NO_2^+ ; (b) NO_2F (N is central).

10.10 Draw Lewis structures of all the important resonance forms of (a) HNO_3 (atom sequence: HONO_2); (b) HAsO_4^{3-} (atom sequence: HOAsO_3^{3-}).

10.11 Draw Lewis structures of all the important resonance forms of (a) N_3^- ; (b) NO_2^- .

10.12 Draw Lewis structures of all the important resonance forms of (a) HCO_2^- (H is attached to C); (b) HBrO_4 (HOBrO_3).

10.13 Draw the Lewis structure with lowest formal charges, and determine the charge of each atom in (a) IF_5 ; (b) AlH_4^- .

10.14 Draw the Lewis structure with lowest formal charges, and determine the charge of each atom in (a) IF_5 ; (b) NO .

10.15 Draw the Lewis structure with lowest formal charges, and determine the charge of each atom in (a) CN^- ; (b) ClO^- .

10.16 Draw the Lewis structure with lowest formal charges, and determine the charge of each atom in (a) ClF_2^+ ; (b) ClNO .

10.17 Draw a Lewis structure for a resonance form of each ion with the lowest possible formal charges, show the charges, and give oxidation numbers of the atoms: (a) BrO_3^- ; (b) SO_3^{2-} .

10.18 Draw a Lewis structure for a resonance form of each ion with the lowest possible formal charges, show the charges, and give oxidation numbers of the atoms: (a) AsO_4^{3-} ; (b) ClO_2^- .

10.19 These species do not obey the octet rule. Draw a Lewis structure for each, and state the type of octet-rule exception: (a) BH_3 (b) AsF_4^- (c) SeCl_4

10.20 These species do not obey the octet rule. Draw a Lewis structure for each, and state the type of octet-rule exception: (a) PF_6^- (b) ClO_3 (c) H_3PO_3 (one P—H bond)

10.21 These species do not obey the octet rule. Draw a Lewis structure for each, and state the type of octet-rule exception: (a) BrF_3 (b) ICl_2^- (c) BeF_2

10.22 These species do not obey the octet rule. Draw a Lewis structure for each, and state the type of octet-rule exception: (a) O_3^- (b) XeF_2 (c) SbF_4^-

Problems in Context

10.23 Molten beryllium chloride reacts with chloride ion from molten NaCl to form the BeCl_4^{2-} ion, in which the Be atom attains an octet. Show the net ionic reaction with Lewis structures.

10.24 Despite many attempts, the perbromate ion (BrO_4^-) was not prepared in the laboratory until about 1970. (In fact, articles were published explaining theoretically why it could never be prepared!) Draw a Lewis structure for BrO_4^- in which all atoms have lowest formal charges.

10.25 Cryolite (Na_3AlF_6) is an indispensable component in the electrochemical production of aluminum. Draw a Lewis structure for the AlF_6^{3-} ion.

10.26 Phosgene is a colorless, highly toxic gas that was employed against troops in World War I and is used today as a key reactant in organic syntheses. From the following resonance structures, select the one with the lowest formal charges:

Comprehensive Problems

2.116 Helium is the lightest noble gas and the second most abundant element (after hydrogen) in the universe.

(a) The radius of a helium atom is 3.1×10^{-11} m; the radius of its nucleus is 2.5×10^{-15} m. What fraction of the spherical atomic volume is occupied by the nucleus (V of a sphere $= \frac{4}{3}\pi r^3$)?

(b) The mass of a helium-4 atom is 6.64648×10^{-24} g, and each of its two electrons has a mass of 9.10939×10^{-28} g. What fraction of this atom's mass is contributed by its nucleus?

2.117 Give the molecular mass of each compound depicted below, and provide a correct name for any that are named incorrectly.

2.118 Polyatomic ions are named by patterns that apply to elements in a given group. Using the periodic table and Table 2.6, give the name of each of the following: (a) SeO_4^{2-} ; (b) AsO_4^{3-} .

OPTIMIZING THE TEXT

The modern chemistry student's learning experience is changing dramatically. To address the changes that students face, a modern text partnered with a suite of robust digital tools must continue to evolve. With each edition, students and instructors alike have been involved in refining this text. From one-on-one interviews, focus groups, and symposia, as well as extensive chapter reviews and class tests, we learned that everyone praises the pioneering molecular art; the stepwise problem-solving approach; the abundant mix of qualitative, quantitative, and applied end-of-chapter problems; and the rigorous *and* student-friendly coverage of mainstream topics.

Global Changes to Every Chapter

Making the concepts clearer through digital learning resources. Students will be able to access digital learning resources throughout this text's eBook. These learning resources present summaries of concepts and worked examples, including videos of chemistry instructors solving problems or modeling concepts that students can view over and over again. Thus, students can have an “office hour” moment at any time.

Student Hot Spots We are very pleased to incorporate real student data points and input, derived from thousands of our users, to help guide our revision. With these data, we were able to both hone our text content when needed and, for particularly challenging concepts, point students to the learning resource videos that can elucidate and reinforce those concepts. You'll see these marginal features throughout the text. Students should log into ALEKS and view the resources through our eBook.

Applying ideas with enhanced problems throughout the chapters. The much admired four-part problem-solving format (plan, solution, check, follow-up) is retained in the tenth edition, in both data-based and molecular-scene *Sample Problems*. Two *Follow-up Problems* are included with each sample problem, as well as a list of *Similar Problems* within the end-of-chapter problem set. *Brief Solutions* for all of the follow-up problems appear at the end of each chapter (rather than providing just a numerical answer in a distant end-of-book appendix, as is typical). The tenth edition has over 250 sample problems and over 500 follow-up problems. In many chapters, several sample and follow-up problems (and their brief solutions) were revised in this edition with two goals in mind. We sought to provide students with a variety of problems that would clearly elucidate concepts and demonstrate problem-solving techniques, while giving students the opportunity to be challenged and gain competence. We also included more intermediate steps in the solutions to both sample and follow-up problems so that students could more easily follow the solutions, and we have included Road Maps with even more sample problems to show students how to plan their solutions.

Re-learning ideas with annotated illustrations. The innovative three-level figures and other art that raised the bar for molecular visualization in chemistry textbooks is still present. Several existing figures have been revised and several new ones added to create an even better teaching tool. We continue to streamline figure legends by placing their content into clarifying annotations with the figures themselves.

Solution Finding the mass (kg) of uranium in 102 kg of pitchblende:

$$\text{Mass (kg) of uranium} = \text{mass (kg) of pitchblende} \times \frac{\text{mass (kg) of uranium in pitchblende}}{\text{mass (kg) of pitchblende}}$$

$$= 102 \text{ kg pitchblende} \times \frac{71.4 \text{ kg uranium}}{84.2 \text{ kg pitchblende}} = 86.5 \text{ kg uranium}$$

Converting the mass of uranium from kg to g:

$$\text{Mass (g) of uranium} = 86.5 \text{ kg uranium} \times \frac{1000 \text{ g}}{1 \text{ kg}} = 8.65 \times 10^4 \text{ g uranium}$$

Finding the mass (in kg) of oxygen in 102 kg of pitchblende:

$$\text{Mass (kg) of oxygen} = \text{mass (kg) of pitchblende} - \text{mass (kg) of uranium}$$

$$= 102 \text{ kg} - 86.5 \text{ kg} = 15.5 \text{ kg oxygen}$$

Converting the mass of oxygen from kg to g:

$$\text{Mass (g) of oxygen} = 15.5 \text{ kg oxygen} \times \frac{1000 \text{ g}}{1 \text{ kg}} = 1.55 \times 10^4 \text{ g oxygen}$$

Check The analysis showed that most of the mass of pitchblende is due to uranium, so the large mass of uranium makes sense. Rounding off to check the math gives

$$\sim 100 \text{ kg pitchblende} \times \frac{70}{85} = 82 \text{ kg uranium}$$

FOLLOW-UP PROBLEMS

2.2A The mineral “fool’s gold” does not contain any gold; instead, it is a compound composed only of the elements iron and sulfur. A 110.0-g sample of fool’s gold contains 51.2 g of iron. What mass of sulfur is in a sample of fool’s gold that contains 86.2 g of iron?

2.2B Silver bromide is the light-sensitive compound coated onto black-and-white film. A 26.8-g sample contains 15.4 g of silver, with bromine as the only other element. How many grams of each element are on a roll of film that contains 3.57 g of silver bromide?

SOME SIMILAR PROBLEMS 2.30–2.33

Student Hot Spot

Student data indicate that you may struggle with using mass fraction to calculate the mass of an element in a compound. Access the eBook to view an additional Learning Resource video on this topic.

Mastering the content with abundant end-of-chapter problem sets. New problems were added to several chapter problem sets, providing students and teachers with abundant choices in a wide range of difficulty and real-life scenarios. The problem sets are more extensive than in most other texts.

Checking knowledge with chapter practice tests. Brand new to this tenth edition is a ten-question multiple-choice practice test at the end of each chapter. The questions on the practice test thoroughly cover the concepts in each chapter, giving students a low-stakes opportunity to check their mastery of the chapter topics. Answers are provided at the end of the test and complete solutions are available in the electronic textbook.

Reflecting the Diverse World Around Us. McGraw Hill believes in unlocking the potential of every learner at every stage of life. To accomplish that, we are dedicated to creating products that reflect, and are accessible to, all the diverse, global customers we serve. Within McGraw Hill, we foster a culture of belonging, and we work with partners who share our commitment to equity, inclusion, and diversity in all forms. In McGraw Hill Higher Education, this includes, but is not limited to, the following:

- Refreshing and implementing inclusive content guidelines around topics including generalizations and stereotypes, gender, abilities/disabilities, race/ethnicity, sexual orientation, diversity of names, and age.
- Enhancing best practices in assessment creation to eliminate cultural, cognitive, and affective bias.
- Maintaining and continually updating a robust photo library of diverse images that reflect our student populations.
- Including more diverse voices in the development and review of our content.
- Strengthening art guidelines to improve accessibility by ensuring that meaningful text and images are distinguishable and perceivable by users with limited color vision and moderately low vision.

Content Changes to Individual Chapters

In addition to the general optimization of concept explanations and problem solutions throughout the text, specific improvements were made to most chapters:

- **Chapter 1** has been reorganized to introduce the topics of significant figures, accuracy, and precision before students begin to perform calculations. There is a new table summarizing the rules for determining significant figures, and the section on dimensional analysis has been rewritten for more clarity.
- **Chapter 2** includes a new figure that illustrates the classification of matter, two new follow-up problems, a revised discussion of mass fraction, mass percentage, and Law of Definite Composition, and a significantly revised section on compound nomenclature. The chapter was reorganized

to collect all discussion of mixtures in one section instead of splitting that discussion between sections.

- **Chapter 3** features new road maps in two sample problems, revised follow-up problems, and a streamlined discussion on empirical, molecular, and structural formulas.
- **Chapter 4** incorporates a new table summarizing redox reaction terms and two revised sample problems. The section on acid-base reactions was heavily revised and simplified. The discussion on molarity is now the first topic in the chapter.
- **Chapter 5** has a new sample problem on partial pressure; the sections on gas laws and kinetic-molecular theory were heavily revised to present these topics with more clarity.
- **Chapter 6** has three sample problems that were revised, with new road maps added; two follow-up problems were revised as well. The Chemical Connections essay on energy use has been updated.
- **Chapter 7** now includes the discussion of all four quantum numbers as the discussion on the spin quantum number was moved from Chapter 8. There is a new figure illustrating blackbody radiation, a revised sample problem, and revised discussions on the electromagnetic spectrum and on Bohr's model of the atom.
- **Chapter 8** includes a revised sample problem on electron configurations as well as a stream-lined discussion about electron configurations of main-group ions.
- **Chapter 9** features a new figure illustrating Coulomb's law and ionic bonding, a revised sample problem on bond length and strength, and revised discussions on bond breaking/formation, polar covalent bonds, and heat released from food, fuels, and explosives. Bond energy values were updated.
- **Chapter 10** presents drawing Lewis structures step by step in a new table format and there is a revised sample problem on resonance structures and formal charges.
- **Chapter 11** features a revised follow-up problem, a modified figure illustrating molecular orbitals that arise from combinations of $2p$ orbitals, and a revision of the discussion on MO theory.
- **Chapter 12** has been reorganized by placing the discussion on intermolecular forces first. There is a new table comparing the properties and features of the three phases of matter and a new figure illustrating the difference between intermolecular versus intramolecular forces.
- **Chapter 13** includes a new figure that shows students how to determine the type of intermolecular forces occurring between solute and solvent, a new figure that illustrates gas solubility versus temperature, and two revised figures that more clearly describes the energy changes that occur in exothermic and endothermic processes. The discussion of intermolecular forces in proteins, DNA, and lipids was moved to Chapter 15, and a discussion of the effect of intermolecular forces on solubility of pesticides was added to this chapter.

- **Chapter 14** incorporates a discussion on the isotopes of hydrogen, including a new table comparing them. This information-packed chapter was streamlined through the removal of a few minor topics.
- **Chapter 15** features three new figures on the types of hydrocarbons, types of amines, and the polypeptide chains in proteins. The section on classes of organic reactions was rewritten for clarity.
- **Chapter 16** includes a new figure illustrating reaction rate and a new figure on enzyme catalysis. The integrated rate law for first-order reaction was presented in a more simplified way.
- **Chapter 17** includes a revision to the discussion of K_p versus K_c , and the discussion on solving equilibrium calculations has been revised for focus and clarity.
- **Chapter 18** incorporates a new table summarizing pH, pOH, $[H_3O^+]$, and $[OH^-]$ for acidic, basic, and neutral solutions. There is a new follow-up problem on K_a calculation, and the section on the acid-base properties of salt solutions was completely rewritten. Updated K_a and K_b values were incorporated into this chapter.
- **Chapter 19** features a new section and sample problem on the common-ion effect. Updated K_{sp} values were added and the sample problem on writing K_{sp} expression has been revised.
- **Chapter 20** includes updated values of standard thermodynamic quantities.
- **Chapter 21** features a new sample problem on balancing redox reactions in acidic solution and streamlined discussions on several topics.
- **Chapter 24** includes a revised discussion of modes of radioactive decay and updated discussions on nuclear reactors and on fusion.

Innovative Topic and Chapter Presentation

Although the topic sequence coincides with that used in most mainstream courses, built-in flexibility allows a wide range of differing course structures:

For courses that follow their own topic sequence, the general presentation, with its many section and subsection breaks and bulleted lists, allows topics to be rearranged, or even deleted, with minimal loss of continuity.

For courses that present several chapters, or topics within chapters, in different orders:

- Redox balancing by the half-reaction method is covered with electrochemistry in Chapter 21, but it can easily be taught with Chapter 4.
- Gases (Chapter 5) can be covered in sequence to explore the mathematical modeling of physical behavior or, with no loss of continuity, just before liquids and solids (Chapter 12) to show the effects of intermolecular forces on the three states of matter.

For courses that use an atoms-first approach for some of the material, Chapters 7 through 13 move smoothly from quantum theory (7) through electron configuration (8), bonding models (9), molecular shape (10), VB and MO bonding theories (11), intermolecular forces in liquids and solids (12), and solutions (13). Immediate applications of these concepts appear in the discussions of periodic patterns in main-group chemistry (Chapter 14) and in the survey of organic chemistry (Chapter 15). Some instructors have also brought forward the coverage of transition elements and coordination compounds (23) as further applications of bonding concepts. (Of course, Chapters 14, 15, and 23 can just as easily remain in their more traditional placement later in the course.)

For courses that emphasize biological/medical applications, many chapters highlight these topics, including the chemistry of polysaccharides, proteins, and nucleic acids (including protein synthesis, DNA replication, and DNA sequencing) (15), as well as introductions to enzyme catalysis (16), biochemical pathways (17), and trace elements in protein function (23).

For courses that stress engineering applications of physical chemistry topics, Chapters 16 through 21 cover kinetics (16), equilibrium in gases (17), acids and bases (18), and aqueous ionic systems (19) and entropy and free energy (20) as they apply to electrochemical systems (21), all in preparation for coverage of the elements in geochemical cycles, metallurgy, and industry in Chapter 22.

ADDITIONAL INSTRUCTOR AND STUDENT RESOURCES FOR YOUR COURSE!

Instructors have access to the following instructor resources:

- **Art** Full-color digital files of all illustrations, photos, and tables in the book can be readily incorporated into lecture presentations, exams, or custom-made classroom materials. In addition, all files have been inserted into PowerPoint slides for ease of lecture preparation.
- **Animations** Numerous full-color animations illustrating important processes are also provided. Harness the visual impact of concepts in motion by importing these files into classroom presentations or online course materials.
- **Accessible PowerPoint Lecture Outlines** Ready-made presentations that combine art and lecture notes are provided for each chapter of the text.
- **Computerized Test Bank** Also among the instructor resources is a computerized test bank. The testing software TestGen[®] can be used to create customized exams quickly. Hundreds of text-specific, open-ended, and multiple-choice questions are included in the question bank.
- **Instructor's Solutions Manual** This supplement, prepared by Patricia Amateis, contains complete, worked-out solutions for *all* the end-of-chapter problems in the text.

ALEKS (Assessment and LEarning in Knowledge Spaces) is a web-based system for individualized assessment and learning available 24/7 over the Internet. ALEKS uses artificial intelligence to accurately determine a students' knowledge and then guides them to the material that they are most ready to learn. ALEKS offers immediate feedback and access to ALEKSPedia—an interactive text that contains concise entries on chemistry topics. ALEKS is also a full-featured course management system with rich reporting features that allow instructors to monitor individual and class performance, set student goals, assign/grade online quizzes, and more. ALEKS allows instructors to spend more time on concepts while ALEKS teaches students practical problem-solving skills. And with ALEKS 360, your student also has access to this text's eBook. Learn more at www.aleks.com/highered/science

McGraw Hill Virtual Labs is a must-see, outcomes-based lab simulation. It assesses a student's knowledge and adaptively corrects deficiencies, allowing the student to learn faster and retain more knowledge with greater success. First, a student's knowledge is adaptively leveled on core learning outcomes: Questioning reveals knowledge deficiencies that are corrected by the delivery of content that is conditional on a student's response. Then, a simulated lab experience requires the student to think and act like a scientist: recording, interpreting, and analyzing data using simulated equipment found in labs and clinics. The student is allowed to make mistakes—a powerful part of the learning experience! A virtual coach provides subtle hints when needed, asks questions about the student's choices, and allows the student to reflect on and correct those mistakes. Whether your need is to overcome the logistical challenges of a traditional lab, provide better lab prep, improve student performance, or make your online experience one that rivals the real world, McGraw Hill Virtual Labs accomplishes it all.

McGraw Hill

COOPERATIVE CHEMISTRY LABORATORY MANUAL

Prepared by Melanie Cooper of Michigan State University, this innovative manual features open-ended problems designed to simulate experience in a research lab. Working in groups, students investigate one problem over a period of several weeks, so they might complete three or four projects during the semester, rather than one preprogrammed experiment per class. The emphasis is on experimental design, analytical problem solving, and communication.

STUDENT SOLUTIONS MANUAL

This supplement contains detailed solutions and explanations for all problems in the main text that have colored numbers.

ACKNOWLEDGMENTS

It would be nearly impossible to put together a more professional, talented, and supportive publishing team than our colleagues at McGraw-Hill Education: Managing Director Kathleen McMahon, Executive Portfolio Manager Ian Townsend, Senior Product Developer Mary Hurley, Content Project Manager Jane Mohr, Senior Marketing Manager Cassie Cloutier, and Director of Digital Content Shirley Hino, Ph.D.

It is a pleasure to work with them; their leadership, knowledge, and encouragement have helped to make this latest edition a reality.

John Murdzek, Ph.D., provided a thorough accuracy check of all the new sample problems, follow-up problems, and end-of-chapter problems, and Louis Poncz, Ph.D., did an excellent job in copyediting the text.

We would also like to thank our reviewers of the ninth edition of the text who contributed to the development of this new tenth edition text:

Break down barriers and build student knowledge

Students start your course with varying levels of preparedness. Some will get it quickly. Some won't. ALEKS is a course assistant that helps you meet each student where they are and provide the necessary building blocks to get them where they need to go. You determine the assignments and the content, and ALEKS will deliver customized practice until they truly get it.

Experience The ALEKS Difference

Easily Identify Knowledge Gaps

Gain greater visibility into student performance so you know immediately if your lessons clicked.

- **ALEKS's "Initial Knowledge Check"** helps accurately evaluate student levels and gaps on day one, so you know precisely where students are at and where they need to go when they start your course.
- **You know when students are at risk of falling behind** through ALEKS Insights so, you can remediate – be it through prep modules, practice questions, or written explanations of video tutorials.
- **Students always know where they are**, how they are doing, and can track their own progress easily.

Gain More Flexibility and Engagement

Teach your course your way, with best-in-class content and tools to immerse students and keep them on track.

- **ALEKS gives you flexibility** to assign homework, share a vast library of curated content including videos, review progress and provide student support, anytime anywhere.
- **You save time** otherwise spent performing tedious tasks while having more control over and impact on your students' learning process.
- **Students gain a deeper level of understanding** through interactive and hands-on assignments that go beyond multiple-choice questions.

with ALEKS® Constructive Learning Paths.

**Narrow the
Equity Gap**

**Count on
Hands-on Support**

Efficiently and effectively create individual pathways for students without leaving anyone behind.

- **ALEKS creates an equitable experience for all** students, making sure they get the support they need to successfully finish the courses they start.
- **You help reduce attrition**, falling enrollment, and further widening of the learning gap.
- **Student success rates improve** – not just better grades, but better learning.

A dedicated Implementation Manager will work with you to build your course exactly the way you want it and your students need it.

- **An ALEKS Implementation Manager** is with you every step of the way through the life of your course.
- **You never have to figure it out on your own** or be your student's customer service. We believe in a consultative approach and take care of all of that for you, so you can focus on your class.
- **Your students benefit** from more meaningful in moments with you, while ALEKS—directed by you—does the rest.

Already benefitting from ALEKS?

- › exponential (scientific) notation (Appendix A)

You are embarking on the study of chemistry, a fascinating science that is fundamental to understanding other natural sciences and one that has a tremendous impact on all of society. Scientists use chemistry as they work on solutions to tough problems such as reducing greenhouse gas emissions to mitigate climate change, tackling the issue of ocean acidification that threatens marine ecosystems, producing drought- and disease-resistant crops to maintain a sufficient world food supply, finding treatments and cures for diseases such as malaria, cancer, and Alzheimer's disease, ending pandemics, producing better batteries and solar cells, promoting renewable energy sources, and providing clean drinking water for people all over the world. There are transformative discoveries to be made in chemistry every day!

A basic understanding of chemistry is crucial for anyone who wants to study biochemistry, geochemistry, food chemistry, agricultural chemistry, forensic chemistry, environmental chemistry, engineering, medicine, or nanotechnology, just to name a few of the many fields that intersect with chemistry. You're going to learn some amazing things in your chemistry course as you begin to view a hidden reality, one filled with incredibly minute particles moving at fantastic speeds and interacting in ways that determine how all matter behaves. This chapter holds the keys to unlock and enter this new world, so let's get started!

IN THIS CHAPTER . . . *We discuss some central ideas about matter and energy, the process of science, units of measurement, and how scientists handle data.*

- › We begin with fundamental concepts about matter and energy and their changes.
- › We take a look at how scientists build models to study nature.
- › We examine modern units for mass, length, volume, density, and temperature.
- › We see that data collection always includes some uncertainty and examine the distinction between accuracy and precision.
- › We apply systematic chemical problem solving to unit conversions.

1.1 SOME FUNDAMENTAL DEFINITIONS

A good place to begin our exploration of chemistry is by defining it and a few central concepts. **Chemistry** is *the scientific study of matter and its properties, the changes that matter undergoes, and the energy associated with those changes*. **Matter** is the “stuff” of the universe: air, glass, planets, students—*anything that has mass and volume*. Chemists want to know the **composition** of matter, *the types and amounts of simpler substances that make it up*. A **substance** is a type of matter that has a defined, fixed composition.

The States of Matter

Matter occurs commonly in *three physical forms* called **states**: solid, liquid, and gas. On the macroscopic scale, each state of matter is defined by the way the sample fills a container (Figure 1.1, *flasks at top*):

- A **solid** has a fixed shape that does not conform to the container shape. Solids are *not* defined by rigidity or hardness: solid iron is rigid and hard, but solid lead is flexible, and solid wax is soft.
- A **liquid** has a varying shape that conforms to the container shape, but only to the extent of the liquid's volume; that is, a liquid has *an upper surface*.
- A **gas** also has a varying shape that conforms to the container shape, but it fills the entire container and, thus, does *not* have a surface.

Figure 1.1 The physical states of matter.

On the atomic scale, each state is defined by the relative positions of its particles (Figure 1.1, *circles at bottom*):

- In a *solid*, the particles lie next to each other in a regular, three-dimensional pattern, or *array*.
- In a *liquid*, the particles also lie close together but move randomly around each other.
- In a *gas*, the particles have large distances between them and move randomly throughout the container.

The Properties of Matter and Its Changes

We learn about matter by observing its **properties**, *the characteristics that give each substance its unique identity*. To identify a person, we might observe height, weight, hair and eye color, fingerprints, and, now, even DNA pattern, until we arrive at a unique identification. To identify a substance, we observe two types of properties, physical and chemical, which are closely related to two types of change that matter undergoes.

Physical Change: No Change in Composition **Physical properties** are characteristics a substance shows *by itself, without changing into or interacting with another substance*. These properties include color, melting point, electrical conductivity, and density. A **physical change** occurs when a substance *alters its physical properties, not its composition*. For example, when ice melts, several physical properties change, such as hardness, density, and ability to flow. But the composition of the sample does *not* change: it is still water. The photograph in Figure 1.2A shows what this change looks like in everyday life. The “blow-up” circles depict a magnified view of the particles making up the sample. In the icicle, the particles lie in the repeating pattern characteristic of a solid, whereas they are jumbled in the liquid droplet; however, *the particles are the same* in both states of water.

Physical change (same substance before and after):

All changes of state of matter are physical changes.

Figure 1.2 The distinction between physical and chemical change.

Source: (A) Paul Morrell/The Image Bank/Getty Images; (B) Stephen Frisch/McGraw Hill

Chemical Change: A Change in Composition Chemical properties are characteristics a substance shows as it changes into or interacts with another substance (or substances). Chemical properties include flammability, corrosiveness, and reactivity with acids. A **chemical change**, also called a **chemical reaction**, occurs when one or more substances are converted into one or more substances with different composition and properties. Figure 1.2B shows the chemical change (reaction) that occurs when you pass an electric current through water: the water decomposes (breaks down) into two other substances, hydrogen and oxygen, that bubble into the tubes. The composition *has* changed: the final sample is no longer water.

Chemical change (different substances before and after):

Let's work through a sample problem that uses atomic-scale scenes to distinguish between physical and chemical change.

SAMPLE PROBLEM 1.1 | Visualizing Change on the Atomic Scale

Problem The scenes below represent an atomic-scale view of a sample of matter, A, undergoing two different changes, left to B and right to C:

Decide whether each depiction shows a physical or a chemical change.

Plan Given depictions of two changes, we have to determine whether each represents a physical or a chemical change. The number and colors of the little spheres that make up each particle tell its “composition.” Samples with particles of the *same* composition but in a different arrangement depict a *physical* change, whereas samples with particles of a *different* composition depict a *chemical* change.

Solution In A, each particle consists of one blue and two red spheres. The particles in A change into two types in B, one made of red and blue spheres and the other made of two red spheres; therefore, they have undergone a **chemical change** to form different particles. The particles in C are the same as those in A, but they are closer together and arranged in a regular pattern; therefore, they have undergone a **physical change**.

FOLLOW-UP PROBLEMS

Brief Solutions for all Follow-up Problems appear at the end of the chapter.

1.1A Is the following change chemical or physical?

1.1B Is the following change chemical or physical?

SOME SIMILAR PROBLEMS 1.1 and 1.80

Table 1.1 illustrates some of the unique physical and chemical properties of the common substance copper.

Table 1.1 | Some Characteristic Properties of Copper

Physical Properties

Easily hammered into sheets (malleable) and drawn into wires (ductile)

Can be melted and mixed with zinc to form brass

Density = 8.95 g/cm^3
Melting point = 1083°C
Boiling point = 2570°C

Chemical Properties

Slowly forms a blue-green carbonate in moist air

Reacts with nitric or sulfuric acid

Slowly forms deep-blue solution in aqueous ammonia

Source: (copper) Stephen Frisch/McGraw Hill; (copper wire) dgstudiodg/iStockphoto/Getty Images; (candlestick) Willard/iStock/Getty Images; (copper carbonate, copper reacting with acid, copper and ammonia) Stephen Frisch/McGraw Hill

Temperature and Changes in Matter Depending on the temperature and pressure of the surroundings, many substances can exist in each of the three physical states and undergo changes in state as well. For example, as the temperature increases, solid water melts to liquid water, which boils to gaseous water (also called *water vapor*). Similarly, as the temperature drops, water vapor condenses to liquid water, and with further cooling, the liquid freezes to ice:

In a steel plant, solid iron melts to liquid (molten) iron and then cools to the solid again. And, far beyond the confines of a laboratory or steel plant, lakes of molten sulfur (a solid on Earth at room temperature) lie on Jupiter's moon Io (*see photo*), which is capped by poles of frozen hydrogen sulfide, a gas on Earth.

The main point is that *a physical change caused by heating can generally be reversed by cooling*. This is *not* generally true for a chemical change. For example, heating iron in moist air causes a chemical reaction that yields the brown, crumbly substance known as rust. Cooling does not reverse this change; rather, another chemical change (or series of them) is required.

The following sample problem provides practice in distinguishing some familiar examples of physical and chemical change.

Many substances that are common on Earth occur in unusual states on other worlds.

Source: NASA-JPL

SAMPLE PROBLEM 1.2

Distinguishing Between Physical and Chemical Change

Problem Decide whether each of the following processes is primarily a physical or a chemical change, and explain briefly:

- (a) Frost forms as the temperature drops on a humid winter night.
- (b) A cornstalk grows from a seed that is watered and fertilized.
- (c) A match ignites to form ash and a mixture of gases.
- (d) Perspiration evaporates when you relax after jogging.
- (e) A silver fork tarnishes slowly in air.

Plan The basic question we ask to decide whether a change is chemical or physical is, “Does the substance change composition or just change form?”

Solution (a) Frost forming is a **physical change**: the drop in temperature changes water vapor (gaseous water) in humid air to ice crystals (solid water).
 (b) A seed growing involves **chemical change**: the seed uses water, substances from air, fertilizer, soil, and energy from sunlight to make complex changes in composition.
 (c) The match burning is a **chemical change**: the combustible substances in the match head are converted into other substances.
 (d) Perspiration evaporating is a **physical change**: the water in sweat changes its state, from liquid to gas, but not its composition.
 (e) Tarnishing is a **chemical change**: silver changes to silver sulfide by reacting with sulfur-containing substances in the air.

FOLLOW-UP PROBLEMS

1.2A Decide whether each of the following processes is primarily a physical or a chemical change, and explain briefly:

- (a) Purple iodine vapor appears when solid iodine is warmed.
- (b) Gasoline fumes are ignited by a spark in an automobile engine's cylinder.
- (c) A scab forms over an open cut.

1.2B Decide whether each of the following processes is primarily a physical or a chemical change, and explain briefly:

- (a) Clouds form in the sky.
- (b) Old milk turns sour.
- (c) Butter is melted to use on popcorn.

SOME SIMILAR PROBLEMS 1.6 and 1.7

The Central Theme in Chemistry

Understanding the properties of a substance and the changes it undergoes leads to the central theme in chemistry: *macroscopic-scale* properties and behavior, those we can see, are the results of *atomic-scale* properties and behavior that we cannot see. The distinction between chemical and physical change is defined by composition, which we study macroscopically. But composition ultimately depends on the makeup of substances at the atomic scale. Similarly, macroscopic properties of substances in any of the three states arise from atomic-scale behavior of their particles. Picturing a chemical event on the molecular scale, even one as common as the flame of a laboratory burner, helps clarify what is taking place. What is happening when water boils or copper melts? What events occur in the invisible world of minute particles that cause a seed to grow, a neon light to glow, or a nail to rust? Throughout the text, we return to this central idea:

*We study **observable** changes in matter to understand their **unobservable** causes.*

The Importance of Energy in the Study of Matter

Physical and chemical changes are accompanied by energy changes. **Energy** is often defined as *the ability to do work*. Essentially, all work involves moving something. Work is done when your arm lifts a book, when a car's engine moves the wheels, or when a falling rock moves the ground as it lands. The object doing the work (arm, engine, rock) transfers some of the energy it possesses to the object on which the work is done (book, wheels, ground).

The total energy an object possesses is the sum of its potential energy and its kinetic energy.

- **Potential energy** is the energy due to the **position** of the object relative to other objects.
- **Kinetic energy** is the energy due to the **motion** of the object.

Let's examine four systems that illustrate the relationship between these two forms of energy: a weight raised above the ground, two balls attached by a spring, two electrically charged particles, and a fuel and its waste products. Two concepts central to all these cases are

1. *When energy is converted from one form to the other, it is conserved, not destroyed.*
2. *Situations of lower energy are more stable and are favored over situations of higher energy, which are less stable.*

The four cases are

- *A weight raised above the ground* (Figure 1.3A). The energy you exert to lift a weight against gravity increases the weight's potential energy (energy due to its position). When you drop the weight, that additional potential energy is converted to kinetic energy (energy due to motion). The situation with the weight elevated and higher in potential energy is *less stable*, so the weight will fall when released, resulting in a situation that is lower in potential energy and *more stable*.
- *Two balls attached by a spring* (Figure 1.3B). When you pull the balls apart, the energy you exert to stretch the relaxed spring increases the system's potential energy. This change in potential energy is converted to kinetic energy when you release the balls. The system of balls and spring is less stable (has more potential energy) when the spring is stretched than when it is relaxed.
- *Two electrically charged particles* (Figure 1.3C). Due to interactions known as *electrostatic forces*, *opposite charges attract each other, and like charges repel each other*. When energy is exerted to move a positive particle away from a negative one, the potential energy of the system increases, and that increase is converted to kinetic energy when the particles are pulled together by the electrostatic attraction. Similarly, when energy is used to move two positive (or two negative) particles together, their potential energy increases and changes to kinetic energy when they are pushed apart by the electrostatic repulsion. Charged particles move naturally to a more stable situation (lower energy).
- *A fuel and its waste products* (Figure 1.3D). Matter is composed of positively and negatively charged particles. *The chemical potential energy of a substance results*

Figure 1.3 Potential energy is converted to kinetic energy. The dashed horizontal lines indicate the potential energy of each system before and after the change.

from the relative positions of its particles and the attractions and repulsions among them. Some substances are higher in potential energy than others. For example, gasoline and oxygen have more chemical potential energy than the exhaust gases they form. This difference is converted into kinetic energy, which moves the car, heats the interior, makes the lights shine, and so on. Similarly, the difference in potential energy between the food and air we take in and the wastes we excrete enables us to move, grow, keep warm, study chemistry, and so on.

› Summary of Section 1.1

- › Chemists study the composition and properties of matter and how they change.
- › Matter exists in three physical states—solid, liquid, and gas. The behavior of each state is due to the arrangement of the particles.
- › Each substance has a unique set of *physical* properties (attributes of the substance itself) and *chemical* properties (attributes of the substance as it interacts with or changes to other substances). Changes in matter can be *physical* (different form of the same substance) or *chemical* (different substance).
- › A physical change caused by heating may be reversed by cooling. But a chemical change caused by heating can be reversed only by other chemical changes.
- › Macroscopic changes result from submicroscopic changes.
- › Changes in matter are accompanied by changes in energy.
- › An object's potential energy is due to its position; an object's kinetic energy is due to its motion. Energy used to lift a weight, stretch a spring, or separate opposite charges increases the system's potential energy, which is converted to kinetic energy as the system returns to its original condition. Energy changes form but is conserved.
- › Chemical potential energy arises from the positions and interactions of a substance's particles. When a higher energy (less stable) substance is converted into a more stable (lower energy) substance, some potential energy is converted into kinetic energy.

1.2 THE SCIENTIFIC APPROACH: DEVELOPING A MODEL

Our prehistoric ancestors survived through *trial and error*, gradually learning which types of stone were hard enough to use for shaping other types, which plants were edible and which poisonous, and so forth. Unlike them, we employ the *quantitative theories* of chemistry to understand materials, make better use of them, and create new ones.

To understand nature, scientists use an approach called the **scientific method**. It is not a stepwise checklist, but rather a process involving creative proposals and tests aimed at objective, verifiable discoveries. There is no single procedure, and luck often plays a key role in discovery. In general terms, the scientific approach includes the following parts (Figure 1.4):

- **Observations.** These are the facts our ideas must explain. The most useful observations are quantitative because they can be analyzed to reveal *trends*. Pieces of quantitative information are **data**. When the same observation is made by many investigators in many situations with no clear exceptions, it is summarized, often in mathematical terms, as a **natural law**. For example, the observation that mass remains constant during chemical change is known as the law of mass conservation (Chapter 2).
- **Hypothesis.** Whether derived from observation or from a “spark of intuition,” a hypothesis is a proposal made to explain an observation. A sound hypothesis need not be correct, but it must be *testable by experiment*. Indeed, a hypothesis is often the reason for performing an experiment: if the results do not support it, the hypothesis must be revised or discarded. *Hypotheses can be altered, but experimental results cannot.*
- **Experiment.** A set of procedural steps that tests a hypothesis, an experiment often leads to a revised hypothesis and new experiments to test it. An experiment typically contains at least two **variables**, quantities that can have more than one value. A well-designed experiment is **controlled** in that it measures the effect of one variable on another while keeping all other variables constant. Experimental results must be *reproducible* by others. Both skill and creativity play a part in experimental design.
- **Model.** Formulating conceptual models, or **theories**, based on *experiments* that test *hypotheses* about *observations* distinguishes scientific thinking from speculation. As hypotheses are revised according to experimental results, a model emerges to explain how a phenomenon occurs. A model is a *simplified*, not an exact, representation of some aspect of nature that we use to *predict* related phenomena. Ongoing experimentation refines the model to account for new facts.

The explanation of **combustion**, the process of burning a material in air, by the young French chemist Antoine Lavoisier (1743–1794) demonstrates the scientific method of thinking. In the late 17th century, *observations* of burning led to the

Figure 1.4 The scientific approach to understanding nature. Hypotheses and models are mental pictures that are revised to match observations and experimental results, *not* the other way around.

hypothesis by many scientists that a loss of an undetectable substance called *phlogiston* occurred during combustion. *Experiments* showing that air is required for burning and that a metal gains mass during combustion led Lavoisier to propose a new *hypothesis*, which he tested repeatedly with quantitative *experiments*. Accumulating evidence supported his developing *model (theory)* that combustion involves combination with a component of air (oxygen). Innumerable *predictions* based on this theory have supported its validity, and Lavoisier himself extended the theory to account for animal respiration and metabolism.

› Summary of Section 1.2

- › The scientific method is a process designed to explain and predict phenomena.
- › Observations lead to hypotheses about how a phenomenon occurs. When repeated with no exceptions, observations may be expressed as a natural law.
- › Hypotheses are tested by controlled experiments and revised when necessary.
- › If reproducible data support a hypothesis, a model (theory) can be developed to explain the observed phenomenon. A good model predicts related phenomena but must be refined whenever conflicting data appear.

1.3 UNITS OF MEASUREMENT

Measurement has a rich history characterized by the search for *exact, invariable standards*. Measuring for purposes of trade, building, and surveying began thousands of years ago, but for most of that time, it was based on standards that could vary: a yard was the distance from the king's nose to the tip of his outstretched arm, and an acre was the area tilled in one day by a farmer with a pair of oxen. Our current system of measurement began in 1790 in France, when a committee, of which Lavoisier was a member, developed the *metric system*. Then, in 1960, another committee in France revised the metric system and established the universally accepted **SI units** (from the French *Système International d'Unités*).

General Features of SI Units

The SI system is based on seven **fundamental units**, or **base units**, each identified with a physical quantity (Table 1.2). All other units are **derived units**, combinations of the seven base units. For example, the derived unit for speed, meters per second (m/s), is the base unit for length (m) divided by the base unit for time (s).

For quantities much smaller or larger than the base unit, we use decimal prefixes and exponential (scientific) notation (Table 1.3). For example, the prefix *kilo-* (symbolized by k) indicates that the unit is one thousand times larger than a base unit, and the prefix *milli-* (m) indicates that the unit is one-thousandth the size of a base unit:

$$\begin{aligned} 1 \text{ kilosecond (1 ks)} &= 1000 \text{ seconds} = 1 \times 10^3 \text{ seconds} \\ 1 \text{ millisecond (1 ms)} &= 0.001 \text{ second} = 1 \times 10^{-3} \text{ second} \end{aligned}$$

Table 1.2 | SI Base Units

Physical Quantity (Dimension)	Unit Name	Unit Abbreviation
Mass	kilogram	kg
Length	meter	m
Time	second	s
Temperature	kelvin	K
Amount of substance	mole	mol
Electric current	ampere	A
Luminous intensity	candela	cd

Table 1.3 | Common Decimal Prefixes Used with SI Units*

Prefix*	Symbol	Conventional Notation	Exponential Notation	Example [using gram (g) [†] or meter (m) ^{**}]
tera	(T)	1,000,000,000,000	1×10^{12}	1 teragram (Tg) = 1×10^{12} g
giga	(G)	1,000,000,000	1×10^9	1 gigagram (Gg) = 1×10^9 g
mega	(M)	1,000,000	1×10^6	1 megagram (Mg) = 1×10^6 g
kilo	(k)	1000	1×10^3	1 kilogram (kg) = 1×10^3 g
hecto	(h)	100	1×10^2	1 hectogram (hg) = 1×10^2 g
deka	(da)	10	1×10^1	1 dekagram (dag) = 1×10^1 g
—	—	1	1×10^0	
deci	(d)	0.1	1×10^{-1}	1 decimeter (dm) = 1×10^{-1} m
centi	(c)	0.01	1×10^{-2}	1 centimeter (cm) = 1×10^{-2} m
milli	(m)	0.001	1×10^{-3}	1 millimeter (mm) = 1×10^{-3} m
micro	(μ)	0.000001	1×10^{-6}	1 micrometer (μm) = 1×10^{-6} m
nano	(n)	0.000000001	1×10^{-9}	1 nanometer (nm) = 1×10^{-9} m
pico	(p)	0.000000000001	1×10^{-12}	1 picometer (pm) = 1×10^{-12} m
femto	(f)	0.000000000000001	1×10^{-15}	1 femtometer (fm) = 1×10^{-15} m

*The prefixes most frequently used by chemists appear in bold type.

[†]The gram is a unit of mass.^{**}The meter is a unit of length.

Note that a mathematically equivalent statement of the second relationship is

$$1000 \text{ milliseconds (ms)} = 1 \text{ second}$$

Because the prefixes are based on powers of 10, SI units are easier to use in calculations than English units. (If you need a review of exponential notation, see Appendix A.)

Some Important SI Units in Chemistry

In this chapter, we discuss units for length, volume, mass, time, density, and temperature; other units are presented in later chapters. Table 1.4 shows some SI quantities for length, volume, and mass, along with their English-system equivalents.

Length The SI base unit of length is the **meter (m)**:

- A meter is the distance light travels in a vacuum in 1/299,792,458 of a second.
- A meter is a little longer than a yard (1 m = 1.094 yd).

Table 1.4 | Common SI–English Equivalent Quantities

Quantity	SI Units	SI Equivalents	English Equivalents	English to SI Equivalent
Length	1 kilometer (km)	1000 (10^3) meters	0.62137 mile (mi)	1 mile = 1.6093 km
	1 meter (m)	100 (10^2) centimeters	1.094 yards (yd)	1 yard = 0.9144 m
	1 meter (m)	1000 millimeters (mm)	39.370 inches (in)	1 foot (ft) = 0.3048 m
	1 centimeter (cm)	0.01 (10^{-2}) meter	0.39370 inch	1 inch = 2.54 cm (exactly)
Volume	1 cubic meter (m^3)	1,000,000 (10^6) cubic centimeters	35.31 cubic feet (ft^3)	1 cubic foot = 0.02832 m^3
	1 cubic decimeter (dm^3)	1000 cubic centimeters	0.2642 gallon (gal)	1 gallon = 3.7854 dm^3
	1 cubic decimeter (dm^3)	1000 cubic centimeters	1.0569 quarts (qt)	1 quart = 0.9464 dm^3
				1 quart = 946.4 cm^3
	1 cubic centimeter (cm^3)	0.001 dm^3	0.03381 fluid ounce	1 fluid ounce = 29.574 cm^3
Mass	1 kilogram (kg)	1000 grams (g)	2.2046 pounds (lb)	1 pound = 0.4536 kg

- A centimeter (10^{-2} m) is about two-fifths of an inch ($1\text{ cm} = 0.3937\text{ in}$; $1\text{ in} = 2.54\text{ cm}$).
- On the atomic scale, nanometers (10^{-9} m) and picometers (10^{-12} m) are used. Many proteins have diameters of about 2 nm; atomic diameters are about 200 pm (0.2 nm).
- An older unit still in use is the angstrom ($1\text{ Å} = 10^{-10}\text{ m} = 0.1\text{ nm} = 100\text{ pm}$).

Volume In chemistry, the significance of length appears when a sample of matter is measured in three dimensions, which gives its **volume (V)**, the amount of space it occupies. The derived SI unit of volume is the **cubic meter (m^3)**:

- A length unit cubed (for example, meters $\times$ meters $\times$ meters = m^3) is a unit of volume since the volume of some objects can be calculated using the relationship length $\times$ width $\times$ height.
- In chemistry, we often use non-SI units, the **liter (L)** and the **milliliter (mL)** (note the uppercase L), to measure volume.
- Medical practitioners measure fluids in cubic decimeters (dm^3), or in cubic centimeters (cm^3):

$$1\text{ L} = 1\text{ dm}^3 = 10^{-3}\text{ m}^3$$

$$1\text{ cm}^3 = 1\text{ mL} = 10^{-3}\text{ dm}^3 = 10^{-3}\text{ L} = 10^{-6}\text{ m}^3$$

- A liter is slightly larger than a quart (qt) ($1\text{ L} = 1.057\text{ qt}$; $1\text{ qt} = 946.4\text{ mL}$); 1 fluid ounce ($\frac{1}{32}$ of a quart) equals 29.57 mL (29.57 cm^3).

Figure 1.5 is a depiction of the two 1000-fold decreases in volume from 1 dm^3 to 1 cm^3 and then to 1 mm^3 . The edge of a 1-m^3 cube would be just a little longer than a yardstick.

Figure 1.5 Some volume relationships in SI: From cubic decimeter (dm^3) to cubic centimeter (cm^3) to cubic millimeter (mm^3).

Figure 1.6 Common laboratory volumetric glassware. **A**, From left to right are two graduated cylinders, a pipet being emptied into a beaker, a buret delivering liquid to an Erlenmeyer flask, and two volumetric flasks. **Inset**, In contact with the glass neck of the flask, the liquid forms a concave meniscus (curved surface). **B**, An automatic pipet delivers a given volume of liquid to each test tube. Source: (A) Stephen Frisch/McGraw Hill; (B) Matthew Jones/18percentgrey/123RF

Figure 1.6A shows some laboratory glassware for working with volumes, and in Figure 1.6B, an automatic pipet transfers liquid accurately *and* quickly.

Mass The quantity of matter an object contains is its **mass**. The SI unit of mass is the **kilogram (kg)**, the only base unit whose name has a prefix.*

The terms *mass* and *weight* have distinct meanings:

- *Mass is constant* because an object's quantity of matter cannot change.
- *Weight is variable* because it depends on the local gravitational field acting on the object.

Because the strength of the gravitational field varies with altitude, you (and other objects) weigh slightly less on a high mountain than at sea level.

Does this mean that a sample weighed on laboratory balances in Miami (sea level) and in Denver (about 1.7 km above sea level) give different results? No, because these balances measure mass, not weight. (We actually “mass” an object when we weigh it on a balance, but we don't use that term.) Mechanical balances compare the object's mass with masses built into the balance, so the local gravitational field pulls on them equally. Electronic (analytical) balances generate an electric field that counteracts the local field, and the current needed to restore the pan to zero is converted to the equivalent mass and displayed.

Figure 1.7 shows the ranges of some common lengths, volumes, and masses.

Time The SI base unit of time is the **second (s)**:

- This time unit is based on an atomic standard; the atomic clock measures the oscillations of microwave radiation absorbed by gaseous cesium atoms cooled to around 10^{-6} K: 1 second is defined as 9,192,631,770 of these oscillations.
- The atomic clock is accurate to within 1 second in 20 million years—over 6000 times more accurate than the best quartz clock!
- Chemists use lasers to measure the speed of extremely fast reactions that occur in a few picoseconds (10^{-12} s) or femtoseconds (10^{-15} s).

*The names of the other base units are used as the root words, but for units of mass we attach prefixes to the word “gram,” as in “microgram” and “kilogram”; thus, we say “milligram,” never “microkilogram.”

Figure 1.7 Some interesting quantities of length (A), volume (B), and mass (C). The vertical scales are exponential.

Temperature Scales

Temperature is a frequently measured quantity in chemistry; there is a noteworthy distinction between temperature and heat:

- **Temperature (T)** is a *measure* of how hot or cold one object is relative to another.
- **Heat** is the *energy* that flows from an object with a higher temperature to an object with a lower temperature. When you hold an ice cube, it feels like the “cold” flows into your hand, but actually, heat flows from your hand to the ice.

In the laboratory, we measure temperature with a **thermometer**, a graduated tube containing a fluid that expands when heated. When the thermometer is immersed in a substance hotter than itself, heat flows from the substance through the glass into the fluid, which expands and rises in the thermometer tube. If a substance is colder than the thermometer, heat flows to the substance from the fluid, which contracts and falls within the tube.

We'll consider three temperature scales: the Celsius ($^{\circ}\text{C}$, formerly called centigrade), the Kelvin (K), and the Fahrenheit ($^{\circ}\text{F}$) scales. The SI base unit of temperature is the **kelvin (K)** (note that no degree sign is used with the symbol for this unit). Figure 1.8 shows some interesting temperatures in the Kelvin scale, which is preferred in scientific

Figure 1.8 Some interesting temperatures.

work (although the Celsius scale is still used frequently). In the United States, the Fahrenheit scale is used for weather reporting, body temperature, and so forth.

The three scales differ in the size of the unit and/or the temperature of the zero point. Figure 1.9 shows the freezing and boiling points of water on the three scales.

- The **Celsius scale** sets water's freezing point at 0°C and its boiling point (at normal atmospheric pressure) at 100°C . Thus, the size of a Celsius degree is $\frac{1}{100}$ of the difference between the freezing and boiling points of water.
- The **Kelvin (absolute) scale** uses the *same size degree* as the Celsius scale; the difference between the freezing point ($+273.15\text{ K}$) and the boiling point ($+373.15\text{ K}$) of water is again 100 degrees, but these temperatures are 273.15 degrees higher on the Kelvin scale because it has a *different zero point*. Absolute zero, 0 K , equals -273.15°C . Thus, on the Kelvin scale, *all temperatures are positive*.

We convert between the Celsius and Kelvin scales by remembering the different zero points: $0^\circ\text{C} = 273.15\text{ K}$, so

$$T(\text{in K}) = T(\text{in } ^\circ\text{C}) + 273.15 \quad (1.1)$$

And, therefore,

$$T(\text{in } ^\circ\text{C}) = T(\text{in K}) - 273.15 \quad (1.2)$$

- The Fahrenheit scale differs from the other scales in its zero point *and* in the size of its degree. Water freezes at 32°F and boils at 212°F . Therefore, 180 Fahrenheit degrees ($212^\circ\text{F} - 32^\circ\text{F}$) represents the same temperature change

Figure 1.9 Freezing and boiling points of water in the Celsius, Kelvin (absolute), and Fahrenheit scales. At the bottom of the figure, a portion of each of the three thermometer scales is expanded to show the sizes of the units.

as 100 Celsius degrees (or 100 kelvins). Because 100 Celsius degrees equal 180 Fahrenheit degrees,

$$1 \text{ Celsius degree} = \frac{180}{100} \text{ Fahrenheit degrees} = \frac{9}{5} \text{ Fahrenheit degrees}$$

To convert a temperature from °C to °F, first change the degree size by multiplying by 9/5 and then adjust the zero point by adding 32 (0°C = 32°F):

$$T (\text{in } ^\circ\text{F}) = \frac{9}{5} T (\text{in } ^\circ\text{C}) + 32 \quad (1.3)$$

To convert a temperature from °F to °C, do the two steps in the opposite order: adjust the zero point by subtracting 32 and then change the degree size by multiplying by 5/9. In other words, solve Equation 1.3 for T (in °C):

$$T (\text{in } ^\circ\text{C}) = [T (\text{in } ^\circ\text{F}) - 32] \frac{5}{9} \quad (1.4)$$

Table 1.5 compares the three temperature scales.

Table 1.5 | The Three Temperature Scales

Scale	Unit	Size of Degree (Relative to K)	Freezing Point of H ₂ O	Boiling Point of H ₂ O	T at Absolute Zero	Conversion
Kelvin (absolute)	kelvin (K)	—	273.15 K	373.15 K	0 K	to °C (Equation 1.1)
Celsius	Celsius degree (°C)	1	0°C	100°C	−273.15°C	to K (Equation 1.2) to °F (Equation 1.3)
Fahrenheit	Fahrenheit degree (°F)	$\frac{5}{9}$	32°F	212°F	−459.67°F	to °C (Equation 1.4)

SAMPLE PROBLEM 1.3 | Converting Units of Temperature

Problem A child has a body temperature of 38.7°C, and normal body temperature is 98.6°F. Does the child have a fever? What is the child's temperature in kelvins?

Plan To see if the child has a fever, we convert from °C to °F (Equation 1.3) and compare it with 98.6°F. Then, to convert the child's temperature in °C to K, we use Equation 1.1.

Solution Converting the temperature from °C to °F:

$$T (\text{in } ^\circ\text{F}) = \frac{9}{5} T (\text{in } ^\circ\text{C}) + 32 = \frac{9}{5}(38.7^\circ\text{C}) + 32 = 101.7^\circ\text{F} \quad \text{Yes, the child has a fever.}$$

Converting the temperature from °C to K:

$$T (\text{in K}) = T (\text{in } ^\circ\text{C}) + 273.15 = 38.7^\circ\text{C} + 273.15 = 311.8 \text{ K}$$

Check From everyday experience, you know that 101.7°F is a reasonable temperature for someone with a fever. In the second step, we can check for a large error as follows: 38.7°C is almost 40°C, and 40 + 273 = 313, which is close to our answer.

Comment The number of digits reported in these answers follow the significant figure rules that are covered in Section 1.4.

FOLLOW-UP PROBLEMS

1.3A Mercury melts at 234 K, lower than any other pure metal. What is its melting point in °C and °F?

1.3B The temperature in a blast furnace used for iron production is 2325°F. What is this temperature in °C and K?

SOME SIMILAR PROBLEMS 1.17 and 1.18

› Summary of Section 1.3

- › The SI unit system consists of seven base units and numerous derived units.
- › Exponential notation and prefixes based on powers of 10 are used to express very small and very large numbers.
- › The SI base unit of length is the meter (m); on the atomic scale, the nanometer (nm) and picometer (pm) are used commonly.
- › Volume (V) units are derived from length units, and the most important volume units are the cubic meter (m³) and the liter (L).
- › The *mass* of an object—the quantity of matter in it—is constant. The SI unit of mass is the kilogram (kg). The *weight* of an object varies with the gravitational field.
- › Temperature (*T*) is a measure of the relative hotness of an object. Heat is energy that flows from an object at higher *T* to one at lower *T*.
- › Temperature scales differ in the size of the degree unit and/or the zero point. For scientific uses, temperature is measured in kelvins (K) or degrees Celsius (°C).

1.4 UNCERTAINTY IN MEASUREMENT: SIGNIFICANT FIGURES

All measuring devices—balances, pipets, thermometers, and so forth—are made to limited specifications, and we use our imperfect senses and skills to read them. Therefore, we can *never* measure a quantity exactly; every measurement includes some **uncertainty** that results from the inexactness of the measuring device and the need to estimate when taking a reading. The device we choose depends on how much uncertainty is acceptable. When you buy potatoes, a supermarket scale that measures in 0.1-kg increments is acceptable:

Measured mass: 2.0 ± 0.1 kg $\longrightarrow$ actual mass: between 1.9 and 2.1 kg

The “ ± 0.1 kg” term expresses the uncertainty in the mass. Needing more certainty than that to weigh a substance, a chemist uses a balance that measures in 0.001-kg increments:

Measured mass: 2.036 ± 0.001 kg $\longrightarrow$ actual mass: between 2.035 and 2.037 kg

The greater number of digits in this measurement means we know the mass of the substance with *more certainty* than we know the mass of the potatoes.

We *always estimate the rightmost digit* of a measurement. The uncertainty can be expressed with the $\pm$ sign, but generally we drop the sign and *assume an uncertainty of one unit in the rightmost digit*. The digits we record, both the certain and the uncertain ones, are called **significant figures**. There are four significant figures in 2.036 kg and two in 2.0 kg. *The greater the number of significant figures, the greater is the certainty of a measurement.* Figure 1.10 shows this point for two thermometers.

Determining Which Digits Are Significant

When you take a measurement or use one in a calculation, you must know which digits are significant; to determine that, use the following guidelines outlined in Table 1.6.

SAMPLE PROBLEM 1.4 | Determining the Number of Significant Figures

Problem For each of the following quantities, underline the zeros that are significant figures (sf) and determine the total number of significant figures. For (e) to (g), express each quantity in exponential notation first.

- | | | |
|----------------------------------|------------------|---------------|
| (a) 0.0030 L | (b) 0.1044 g | (c) 53,069 mL |
| (d) 3040 kg | (e) 0.00004715 m | (f) 57,600. s |
| (g) 0.0000007160 cm ³ | | |

Figure 1.10 The number of significant figures in a measurement.

Table 1.6 | Determination of Significant Digits in a Measurement

Rule	Examples (Significant digits are marked in red)	Comments
All nonzero digits in a measurement are significant.	512, 1938	
All zeros between nonzero digits are significant.	502, 19,038	
Leading zeros that occur before the first nonzero digit are not significant.	0.00502, 0.0235	Notice that leading zeros drop out when the number is written in exponential (scientific) notation: 5.02×10^{-3} , 2.35×10^{-2}
Trailing zeros are significant <i>if</i> the measurement has a decimal point.	1.1300, 0.04020	Notice that trailing significant zeros remain when the number is written in exponential notation: 4.020×10^{-2}
Trailing zeros without a decimal point are assumed not to be significant.	6500	To indicate that trailing zeros are to be considered significant: - Add a terminal decimal point: 6500. - Clarify the significant zeros with exponential notation: 6.500×10^{-2} or 6.50×10^{-2} or 6.5×10^{-2}

Plan We determine the number of significant figures by using the guidelines outlined in Table 1.6, paying particular attention to the position of zeros in relation to the decimal point, and underlining the zeros that are significant.

Solution (a) 0.0030 L has 2 sf

(b) 0.1044 g has 4 sf

(c) 53,069 mL has 5 sf

(d) 3040 kg has 3 sf

(e) 0.00004715 m, or 4.715×10^{-5} m, has 4 sf

(f) 57,600. s, or 5.7600×10^4 s, has 5 sf

(g) 0.0000007160 cm³, or 7.160×10^{-7} cm³, has 4 sf

Check Be sure not to count leading zeros, or trailing zeros in quantities without a decimal point, as significant. Notice that leading zeros disappear when the quantity is expressed in exponential notation in (e) and (g), confirming that they are not significant.

FOLLOW-UP PROBLEMS

1.4A For each of the following quantities, underline the zeros that are significant figures and determine the total number of significant figures (sf).

- (a) 31.070 mg (b) 0.06060 g (c) 850.°C

1.4B For each of the following quantities, underline the zeros that are significant figures and determine the total number of significant figures (sf). Express each quantity in exponential notation first.

- (a) 200.0 mL (b) 0.00000390 m (c) 0.000401 L

SOME SIMILAR PROBLEMS 1.22 and 1.23

Significant Figures: Calculations and Rounding Off

Measuring several quantities typically results in data with differing numbers of significant figures. In a calculation, we keep track of the number in each quantity so that we don't have more significant figures (more certainty) in the answer than in the data. If we do have too many significant figures, we must **round off** the answer.

The general rule for rounding is:

- *The least certain measurement sets the limit on certainty for the entire calculation and determines the number of significant figures in the final answer.*

Rules for Arithmetic Operations The two rules in arithmetic calculations are

1. *For multiplication and division:*

- The answer contains the same number of significant figures as there are in the measurement with the *fewest significant figures*.

Suppose you want to find the volume of a sheet of a new graphite composite. The length (9.2 cm) and width (6.8 cm) are obtained with a ruler, and the thickness (0.3744 cm) with a set of calipers. The calculation is

$$\text{Volume (cm}^3\text{)} = 9.2 \text{ cm} \times 6.8 \text{ cm} \times 0.3744 \text{ cm} = 23.422464 \text{ cm}^3 = 23 \text{ cm}^3$$

No. of significant figures: 2 2 4 2

Even though your calculator may show 23.422464 cm³, you report 23 cm³, the answer with two significant figures, the same as in the measurements with the lower number of significant figures. After all, if the length and width have only two significant figures, you can't possibly know the volume with more certainty.

2. *For addition and subtraction:*

- The answer has the same number of *decimal places* as there are in the measurement with the *fewest decimal places*.

Suppose you want the total volume after adding water to a protein solution: you have 83.5 mL of solution in a graduated cylinder and add 23.28 mL of water from a buret; the calculation is shown. Here the calculator shows 106.78 mL, but you report the volume as 106.8 mL, because the measurement with fewer decimal places (83.5 mL) has only one decimal place.

$$\begin{array}{r} 83.5 \text{ mL} \\ + 23.28 \text{ mL} \\ \hline 106.78 \text{ mL} \end{array}$$

Answer: Volume = 106.8 mL

Note that the answer, 106.8 mL, has four significant figures, whereas the volume of the protein solution, 83.5 mL, has only three significant figures. In addition and subtraction, the number of significant figures is determined by *the number of decimal places, not the total number of significant figures*, in the measurements.

Rules for Rounding Off You usually need to round off the final answer to the proper number of significant figures or decimal places. Notice that, in calculating the volume

of the graphite composite, we removed the extra digits, but in calculating the total volume of the protein solution, we removed the extra digit and increased the last digit by one. The general rule for rounding is that *the least certain measurement sets the limit on the certainty of the final answer*. Here are detailed rules for rounding off:

1. If the digit removed is **more than 5**, the preceding number increases by 1: $5.379 \rightarrow 5.38$ (three significant figures); $5.379 \rightarrow 5.4$ (two significant figures)
2. If the digit removed is **less than 5**, the preceding number remains the same: $0.2413 \rightarrow 0.241$ (three significant figures); $0.2413 \rightarrow 0.24$ (two significant figures)
3. If the digit removed is **5**, the preceding number increases by 1 if it is odd and remains the same if it is even: $17.75 \rightarrow 17.8$; $17.65 \rightarrow 17.6$
If the 5 is followed only by zeros, rule 3 is followed; if the 5 is followed by nonzeros, rule 1 is followed: $17.7500 \rightarrow 17.8$; $17.6500 \rightarrow 17.6$; $17.6513 \rightarrow 17.7$
4. *Always carry one or two additional significant figures through a multistep calculation and round off the final answer only.* Don't be concerned if you string together a calculation to check a sample or follow-up problem and find that your answer differs in the last decimal place from the one in the book. To show you the correct number of significant figures in text calculations, *we round off intermediate steps*, and that process may sometimes change the last digit.

Note that, unless you set a limit on your calculator, it gives answers with too many significant figures and you must round the displayed result.

Significant Figures in the Lab The measuring device you choose determines the number of significant figures you can obtain. Suppose an experiment requires a solution made by dissolving a solid in a liquid. You weigh the solid on an analytical balance and obtain a mass with five significant figures. It would make sense to measure the liquid with a buret or a pipet, which measures volumes to more significant figures than a graduated cylinder. If you did choose the cylinder, you would have to round off more digits, and some certainty you attained for the mass value would be wasted (Figure 1.11). With experience, you'll choose a measuring device based on the number of significant figures you need in the final answer.

Exact Numbers **Exact numbers** have no uncertainty associated with them. Some are part of a unit conversion: by definition, there are exactly 60 minutes in 1 hour, 1000 micrograms in 1 milligram, and 2.54 centimeters in 1 inch. Other exact numbers result from actually counting items: there are exactly 3 coins in my hand, 26 letters in the English alphabet, and so forth. Therefore, unlike measured quantities, *exact numbers do not limit the number of significant figures in a calculation*.

Figure 1.11 Significant figures and measuring devices. The mass measurement (6.8605 g) has more significant figures than the volume measurement (68.2 mL).

Source: (both) Stephen Frisch/McGraw Hill

SAMPLE PROBLEM 1.5 | Significant Figures and Rounding

Problem Perform the following calculations and round the answers to the correct number of significant figures:

$$(a) \frac{16.205 \text{ cm}^2 - 1.5 \text{ cm}^2}{7.081 \text{ cm}} \quad (b) \frac{48.0 \text{ g}}{11.55 \text{ cm}^3}$$

Plan We use the rules just presented in the text: (a) We subtract before we divide.

$$\text{Solution (a)} \quad \frac{16.205 \text{ cm}^2 - 1.5 \text{ cm}^2}{7.081 \text{ cm}} = \frac{14.7 \text{ cm}^2}{7.081 \text{ cm}} = 2.08 \text{ cm}$$

The answer to the subtraction in the numerator (14.705) is rounded to 14.7 with one decimal place because 1.5 has only one decimal place. We retain 3 sf in the final answer because 14.7 has 3 sf.

$$(b) \frac{48.0 \text{ g}}{11.55 \text{ cm}^3} = 4.16 \text{ g/cm}^3$$

We retain 3 sf in the answer because there are 3 sf in 48.0.

Check Rounding to the nearest whole number is always a good way to check:

(a) $(16 - 2)/7 \approx 2$; (b) $50/12 \approx 4$.

FOLLOW-UP PROBLEMS

1.5A Perform the following calculation and round the answer to the correct number of significant figures:

$$\frac{45.61 \text{ mL} + 62.3 \text{ mL}}{73.55 \text{ s}}$$

1.5B Perform the following calculation and round the answer to the correct number of significant figures:

$$\frac{154.64 \text{ g} - 35.26 \text{ g}}{4.20 \text{ cm} \times 5.12 \text{ cm} \times 6.752 \text{ cm}}$$

SOME SIMILAR PROBLEMS 1.26–1.29, 1.36, and 1.37

Precision, Accuracy, and Instrument Calibration

We may use the words *precision* and *accuracy* interchangeably in everyday speech, but for scientific measurements they have distinct meanings. **Precision**, or *reproducibility*, refers to how close the measurements in a series are to each other, and **accuracy** refers to how close each measurement is to the actual value. These terms are related to two widespread types of error:

1. **Systematic error** produces values that are *either* all higher or all lower than the actual value. This type of error is part of the experimental system, often caused by a faulty device or by a consistent mistake in taking a reading.
2. **Random error**, in the absence of systematic error, produces values that are higher *and* lower than the actual value. Random error *always* occurs, but its size depends on the measurer's skill and the instrument's precision.

Precise measurements have low random error, that is, small deviations from the average. *Accurate measurements have low systematic error and, generally, low random error*. In some cases, when many measurements have a high random error, the *average* may still be accurate.

Suppose each of four students measures 25.0 mL of water in a preweighed graduated cylinder and then weighs the water *plus* cylinder on a balance. If the density of water is 1.00 g/mL at the temperature of the experiment, the *actual* mass of 25.0 mL of water is 25.0 g. Each student performs the operation four times, subtracts the mass of the empty cylinder, and obtains one of four graphs (Figure 1.12):

- In graph A, random error is small; that is, precision is high (the weighings are reproducible). Accuracy is high as well, as all of the values are close to 25.0 g.
- Random error is also small and precision high in graph B, but accuracy is low; there is systematic error, with all of the weighings above 25.0 g.

Figure 1.12 Precision and accuracy in a laboratory calibration.

- In graph C, random error is large and precision is low. But since the average of the scattered values is close to the actual value, systematic error is low.
- Graph D also exhibits large random error, but note that there is also significant systematic error in this case, resulting in low accuracy (all the values are high).

Systematic error can be taken into account through **calibration**, comparing the measuring device with a known standard. The systematic error in graph B, for example, might be caused by a poorly manufactured cylinder that reads “25.0” when it actually contains about 27 mL. If that cylinder had been calibrated, the students could have adjusted all volumes measured with it. The students also should calibrate the balance with standardized masses.

› Summary of Section 1.4

- › The final digit of a measurement is always estimated. Thus, all measurements have some uncertainty, which is expressed by the number of significant figures.
- › The certainty of a calculated result depends on the certainty of the data, so the answer has as many significant figures as in the least certain measurement.
- › Excess digits are rounded off in the final answer according to a set of rules.
- › The choice of laboratory device depends on the certainty needed.
- › Exact numbers have as many significant figures as the calculation requires.
- › *Precision* refers to how close values are to each other, and *accuracy* refers to how close values are to the actual value.
- › Systematic errors give values that are either all higher or all lower than the actual value. Random errors give some values that are higher and some that are lower than the actual value.
- › Precise measurements have low random error; accurate measurements have low systematic error and low random error.
- › A systematic error is often caused by faulty equipment and can be compensated for by calibration.

1.5 UNITS AND CONVERSION FACTORS IN CALCULATIONS

All measured quantities consist of a number *and* a unit: the mass of a beaker, for example, is “102 g”, not “102.” In calculations involving measurements, we often find it necessary to change, or convert, from one unit to another. To do so, we use **conversion factors**, *ratios used to express a quantity in different units*. The use of conversion factors in calculations is referred to as the factor-label method, or **dimensional analysis** (because units represent physical dimensions). We will use this approach, discussed in this section, throughout the text. Dimensional analysis requires *units to be included in all calculations*.

Constructing and Choosing Conversion Factors

Suppose we want to know the distance of a 150. mile car trip in feet. To convert miles to feet, we use *equivalent quantities*,

$$1 \text{ mi} = 5280 \text{ ft}$$

from which we can construct two conversion factors, ratios of equivalent quantities that are equal to 1. Dividing both sides by 5280 ft gives one conversion factor (shown in blue):

$$\frac{1 \text{ mi}}{5280 \text{ ft}} = \frac{5280 \cancel{\text{ft}}}{5280 \cancel{\text{ft}}} = 1$$

And, dividing both sides by 1 mi gives the other conversion factor (the inverse):

$$\frac{1 \cancel{\text{mi}}}{1 \cancel{\text{mi}}} = \frac{5280 \text{ ft}}{1 \text{ mi}} = 1$$

Since the numerator and denominator of a conversion factor are equal, multiplying a quantity by a conversion factor is the same as multiplying by 1. Thus, *even though the number and unit change, the size of the quantity remains the same.*

To convert the distance from miles to feet, we choose the conversion factor with miles in the denominator, because it cancels miles and gives the answer in feet:

$$\text{Distance (ft)} = 150 \underset{\text{mi}}{\cancel{\text{mi}}} \times \frac{5280 \text{ ft}}{1 \underset{\text{mi}}{\cancel{\text{mi}}}} = 792,000 \text{ ft}$$

To convert the distance back from feet to miles, we choose the conversion factor with feet in the denominator because it cancels feet and gives the answer in miles:

$$\text{Distance (mi)} = 792,000 \underset{\text{ft}}{\cancel{\text{ft}}} \times \frac{1 \text{ mi}}{5280 \underset{\text{ft}}{\cancel{\text{ft}}}} = 150. \text{ mi}$$

The *conversion factor you choose must cancel all units except those you want in the answer.* Therefore, set the unit you are converting *from* (beginning unit) in the *opposite position in the conversion factor* (numerator or denominator) so that it cancels and you are left with the unit you are converting *to* (final unit):

$$\underset{\text{beginning unit}}{\cancel{\text{beginning unit}}} \times \frac{\text{final unit}}{\underset{\text{beginning unit}}{\cancel{\text{beginning unit}}}} = \text{final unit} \quad \text{as in} \quad \underset{\text{mi}}{\cancel{\text{mi}}} \times \frac{\text{ft}}{\underset{\text{mi}}{\cancel{\text{mi}}}} = \text{ft}$$

Converting Between Unit Systems

We use this procedure to convert units within the English (or American) system, units within the International system, or between English and SI units. Suppose we know that the height of the Empire State building in New York City is 1454 ft; we can find its height in miles as

$$\text{Height (mi)} = 1454 \underset{\text{ft}}{\cancel{\text{ft}}} \times \frac{1 \text{ mi}}{5280 \underset{\text{ft}}{\cancel{\text{ft}}}} = 0.2754 \text{ mi}$$

Now, we want its height in kilometers (km). The equivalent quantities (see Table 1.4) are

$$1.6093 \text{ km} = 1 \text{ mi}$$

Because we are converting *from* miles *to* kilometers, we use the conversion factor with miles in the denominator in order to cancel miles:

$$\text{Height (km)} = 0.2754 \underset{\text{mi}}{\cancel{\text{mi}}} \times \frac{1.6093 \text{ km}}{1 \underset{\text{mi}}{\cancel{\text{mi}}}} = 0.4432 \text{ km}$$

Notice that kilometers are *smaller* than miles, so this conversion factor gave us an answer with a *larger* number (0.4432 is larger than 0.2754).

If we want the height of this building in meters (m), we use the equivalent quantities 1 km = 1000 m to construct the conversion factor:

$$\text{Height (m)} = 0.4432 \underset{\text{km}}{\cancel{\text{km}}} \times \frac{1000 \text{ m}}{1 \underset{\text{km}}{\cancel{\text{km}}}} = 443.2 \text{ m}$$

In longer calculations, we often string together several conversion steps:

$$\text{Height (m)} = 1454 \underset{\text{ft}}{\cancel{\text{ft}}} \times \frac{1 \underset{\text{mi}}{\cancel{\text{mi}}}}{5280 \underset{\text{ft}}{\cancel{\text{ft}}}} \times \frac{1.6093 \underset{\text{km}}{\cancel{\text{km}}}}{1 \underset{\text{mi}}{\cancel{\text{mi}}}} \times \frac{1000 \text{ m}}{1 \underset{\text{km}}{\cancel{\text{km}}}} = 443.2 \text{ m}$$

To ensure that conversion factors are being properly used to cancel units, all calculations must include units as well as numbers!

A Systematic Approach to Solving Chemistry Problems

The approach used in this book to solve problems emphasizes reasoning, not memorizing, and is based on a simple idea: plan how to solve the problem *before* you try

Student Hot Spot

Student data indicate that you may struggle with conversion factors. Access the eBook to view an additional Learning Resource video on this topic.

to solve it, then check your answer, and practice with similar follow-up problems. In general, the sample problems consist of several parts:

1. **Problem.** This part states all the information you need to solve the problem, usually framed in some interesting context.
2. **Plan.** This part helps you *think* about the solution *before* juggling numbers and pressing calculator buttons. There is often more than one way to solve a problem, and the given plan is one possibility. The plan will
 - Clarify the known and unknown: what information do you have, and what are you trying to find?
 - Suggest the steps from known to unknown: what ideas, conversions, or equations are needed?
 - Present a road map (especially in early chapters), a flow diagram of the plan. The road map has a box for each intermediate result and an arrow showing the step (conversion factor or operation) used to get to the next box.
3. **Solution.** This part shows the calculation steps in the same order as in the plan (and the road map).
4. **Check.** This part helps you check that your final answer makes sense: Are the units correct? Did the change occur in the expected direction? Is it reasonable chemically? To avoid a large math error, we also often do a rough calculation and see if we get an answer “in the same ballpark” as the actual result. Here’s a typical “ballpark” calculation from everyday life. You are in a clothing store and buy three shirts at \$14.97 each. With a 5% sales tax, the bill comes to \$47.16. In your mind, you know that \$14.97 is about \$15, and 3 times \$15 is \$45; with the sales tax, the cost should be a bit more. So, your quick mental calculation *is* in the same ballpark as the actual cost.
5. **Comment.** This part appears occasionally to provide an application, an alternative approach, a common mistake to avoid, or an overview.
6. **Follow-up Problems.** This part presents similar problems that require you to apply concepts and/or methods used in solving the sample problem.
7. **Some Similar Problems.** This part lists a few more problems (found at the end of each chapter) for practice.

Of course, you can’t learn to solve chemistry problems, any more than you can learn to swim, by reading about it, so here are a few suggestions:

- Follow along in the sample problem with pencil, paper, and calculator.
- Try the follow-up problems as soon as you finish the sample problem. A very useful feature called Brief Solutions to Follow-up Problems appears at the end of each chapter, allowing you to compare your solution steps and answers.
- Read the sample problem and text again if you have trouble.
- The end-of-chapter problems review and extend the concepts and skills in the chapter, so work as many as you can. (Answers are given in Appendix E in the back of the book for problems with a colored number.)

Let’s apply this systematic approach in some unit-conversion problems. Refer to Tables 1.3 and 1.4 as you work through these problems.

SAMPLE PROBLEM 1.6 | Converting Units of Length

Problem To wire your home sound system, you need 325 centimeters (cm) of speaker wire that sells for \$0.15/ft. How much does the wire cost?

Plan We know the length of wire in centimeters (325 cm) and the price in dollars per foot (\$0.15/ft). We can find the unknown cost of the wire by converting the length from centimeters to inches (in) and from inches to feet. The price gives us the equivalent

Road Map

quantities (1 ft = \$0.15) that allow us to convert from feet of wire to cost in dollars. The road map starts with the known quantity of 325 cm and moves through the calculation steps to the unknown.

Solution Converting the known length from centimeters to inches: the equivalent quantities beside the road map arrow are needed to construct the conversion factor. We choose 1 in/2.54 cm, rather than 2.54 cm/1 in, because it gives an answer in inches:

$$\begin{aligned}\text{Length (in)} &= \text{length (cm)} \times \text{conversion factor} \\ &= 325 \text{ cm} \times \frac{1 \text{ in}}{2.54 \text{ cm}} = 128 \text{ in}\end{aligned}$$

Converting the length from inches to feet:

$$\begin{aligned}\text{Length (ft)} &= \text{length (in)} \times \text{conversion factor} \\ &= 128 \text{ in} \times \frac{1 \text{ ft}}{12 \text{ in}} = 10.7 \text{ ft}\end{aligned}$$

Converting the length in feet to cost in dollars:

$$\begin{aligned}\text{Cost (\$)} &= \text{length (ft)} \times \text{conversion factor} \\ &= 10.7 \text{ ft} \times \frac{\$0.15}{1 \text{ ft}} = \$1.60\end{aligned}$$

Check The units are correct for each step. The conversion factors make sense in terms of the relative unit sizes: the number of inches is *smaller* than the number of centimeters (an inch is *larger* than a centimeter), and the number of feet is *smaller* than the number of inches. The total cost seems reasonable: a little more than 10 ft of wire at \$0.15/ft should cost a little more than \$1.50.

Comment 1. We could also have strung the three steps together:

$$\text{Cost (\$)} = 325 \text{ cm} \times \frac{1 \text{ in}}{2.54 \text{ cm}} \times \frac{1 \text{ ft}}{12 \text{ in}} \times \frac{\$0.15}{1 \text{ ft}} = \$1.60$$

2. There are usually alternative sequences in unit-conversion problems. Here, for example, we would get the same answer if we first converted the cost of wire from \$/ft to \$/cm and kept the wire length in cm. Try it yourself.

FOLLOW-UP PROBLEMS

SOME SIMILAR PROBLEMS 1.48–1.51

Road Map

SAMPLE PROBLEM 1.7 | Converting Units of Volume

Problem The volume of an irregularly shaped solid can be determined from the volume of water it displaces. A graduated cylinder contains 19.9 mL of water. When a small piece of galena, an ore of lead, is added to the cylinder, it sinks and the volume increases to 24.5 mL. What is the volume of the piece of galena in cm³ and in L?

Plan We have to find the volume of the galena from the change in volume of the cylinder contents. The volume of galena in mL is the difference before (19.9 mL) and after (24.5 mL) adding it. Since mL and cm³ represent identical volumes, the volume in mL equals the volume in cm³. We then use equivalent quantities (1 mL = 10^{−3} L) to convert mL to L. The road map shows these steps.

Solution Finding the volume of galena:

$$\text{Volume (mL)} = \text{volume after} - \text{volume before} = 24.5 \text{ mL} - 19.9 \text{ mL} = 4.6 \text{ mL}$$

Converting the volume from mL to cm³:

$$\text{Volume (cm}^3\text{)} = \text{volume (mL)} \times \text{conversion factor} = 4.6 \cancel{\text{ mL}} \times \frac{1 \text{ cm}^3}{1 \cancel{\text{ mL}}} = 4.6 \text{ cm}^3$$

Converting the volume from mL to L:

$$\text{Volume (L)} = \text{volume (mL)} \times \text{conversion factor} = 4.6 \cancel{\text{ mL}} \times \frac{10^{-3} \text{ L}}{1 \cancel{\text{ mL}}} = 4.6 \times 10^{-3} \text{ L}$$

Check The units and magnitudes of the answers seem correct, and it makes sense that the volume in mL would have a number 1000 times larger than the same volume in L.

FOLLOW-UP PROBLEMS

1.7A Within a cell, proteins are synthesized on particles called ribosomes. Assuming ribosomes are spherical, what is the volume (in dm³ and μL) of a ribosome whose average diameter is 21.4 nm (V of a sphere = $\frac{4}{3}\pi r^3$)? Draw a road map to show how you planned the solution.

1.7B During an eruption, the famous geyser Old Faithful in Yellowstone National Park can expel as much as 8400 gal of water. What is this volume in liters (L)? Draw a road map to show how you planned the solution.

SOME SIMILAR PROBLEMS 1.58 and 1.59

SAMPLE PROBLEM 1.8 | Converting Units of Mass

Problem Many international computer communications are carried by optical fibers in cables laid along the ocean floor. If one strand of optical fiber weighs 1.19×10^{-3} lb/m, what is the mass (in kg) of a cable made of six strands of optical fiber, each long enough to link New York and Paris (8.84×10^3 km)?

Plan We have to find the mass (in kg) of a known length of cable (8.84×10^3 km); we are given equivalent quantities for mass and length of a fiber (1.19×10^{-3} lb = 1 m) and for number of fibers and a cable (6 fibers = 1 cable), which we can use to construct conversion factors. Let's first find the mass of one fiber and then the mass of cable. As shown in the road map, we convert the length of one fiber from km to m and then find its mass (in lb) by converting m to lb. Then we multiply the fiber mass by 6 to get the cable mass, and finally convert lb to kg.

Solution Converting the fiber length from km to m:

$$\text{Length (m) of fiber} = 8.84 \times 10^3 \cancel{\text{ km}} \times \frac{10^3 \text{ m}}{1 \cancel{\text{ km}}} = 8.84 \times 10^6 \text{ m}$$

Converting the length of one fiber to mass (lb):

$$\text{Mass (lb) of fiber} = 8.84 \times 10^6 \cancel{\text{ m}} \times \frac{1.19 \times 10^{-3} \text{ lb}}{1 \cancel{\text{ m}}} = 1.05 \times 10^4 \text{ lb}$$

Finding the mass of the cable (lb):

$$\text{Mass (lb) of cable} = \frac{1.05 \times 10^4 \text{ lb}}{1 \cancel{\text{ fiber}}} \times \frac{6 \cancel{\text{ fibers}}}{1 \text{ cable}} = 6.30 \times 10^4 \text{ lb/cable}$$

Converting the mass of cable from lb to kg:

$$\text{Mass (kg) of cable} = \frac{6.30 \times 10^4 \cancel{\text{ lb}}}{1 \cancel{\text{ cable}}} \times \frac{1 \text{ kg}}{2.2046 \cancel{\text{ lb}}} = 2.86 \times 10^4 \text{ kg/cable}$$

Check The units are correct. Let's think through the relative sizes of the answers to see if they make sense: The number of m should be 10^3 larger than the number of km. If 1 m of fiber weighs about 10^{-3} lb, then about 10^7 m should weigh about 10^4 lb. The cable mass should be six times as much as that, or about 6×10^4 lb. Since 1 lb is about $\frac{1}{2}$ kg, the number of kg should be about half the number of lb.

FOLLOW-UP PROBLEMS

1.8A An intravenous nutrient solution is delivered to a hospital patient at a rate of 1.5 drops per second. If a drop of solution weighs 65 mg on average, how many kilograms are delivered in 8.0 h? Draw a road map to show how you planned the solution.

Road Map

1.8B Nutritional tables give the potassium content of a standard apple (about 3 apples per pound) as 159 mg. How many grams of potassium are in 3.25 kg of apples? Draw a road map to show how you planned the solution.

SOME SIMILAR PROBLEMS 1.54 and 1.55

Converting Units Raised to a Power When you must convert units that are raised to a power, such as in^2 or cm^3 , both the number and the unit in the conversion factor must be raised to that power. For example:

Convert from in^2 to cm^2 :

$$1 \text{ in} = 2.54 \text{ cm}$$

$$1^2 \text{ in}^2 = (2.54)^2 \text{ cm}^2$$

Convert from cm^3 to m^3 :

$$100 \text{ cm} = 1 \text{ m}$$

$$(100)^3 \text{ cm}^3 = 1^3 \text{ m}^3$$

SAMPLE PROBLEM 1.9 | Converting Units Raised to a Power

Problem A furniture factory needs 31.5 ft^2 of fabric to upholster one chair. Its Dutch supplier sends the fabric in bolts that hold exactly 200 m^2 . How many chairs can be upholstered with 3 bolts of fabric?

Plan We are given a known number of fabric bolts (3 bolts), which can be converted to amount of fabric in m^2 using the given equivalent quantities ($1 \text{ bolt} = 200 \text{ m}^2$ fabric). We convert the amount of fabric from m^2 to ft^2 and use the equivalent quantities (31.5 ft^2 of fabric = 1 chair) to find the number of chairs (see the road map).

Solution Converting from number of bolts to amount of fabric in m^2 :

$$\text{Amount (m}^2\text{) of fabric} = 3 \text{ bolts} \times \frac{200 \text{ m}^2}{1 \text{ bolt}} = 600 \text{ m}^2$$

Converting the amount of fabric from m^2 to ft^2 : since $0.3048 \text{ m} = 1 \text{ ft}$, we have $(0.3048)^2 \text{ m}^2 = (1)^2 \text{ ft}^2$, so

$$\text{Amount (ft}^2\text{) of fabric} = 600 \text{ m}^2 \times \frac{1 \text{ ft}^2}{(0.3048)^2 \text{ m}^2} = 6460 \text{ ft}^2$$

Finding the number of chairs:

$$\text{Number of chairs} = 6460 \text{ ft}^2 \times \frac{1 \text{ chair}}{31.5 \text{ ft}^2} = 205 \text{ chairs}$$

Check Since $1 \text{ ft} = 0.3048 \text{ m}$, 1 ft is a little less than $\frac{1}{3}$ of a meter, which means that 3.3 ft is about the same as 1 m . We are using squared length units, and $(3.3 \text{ ft})^2$, or 11 ft^2 , is about the same as 1 m^2 . Multiplying the amount of fabric in m^2 by 11 gives 6600 ft^2 of fabric. Each chair requires about 30 ft^2 of fabric, so 6600 ft^2 will upholster 220 chairs, a number close to our answer.

Comment When using conversion factors raised to a power, be certain to raise *both* the number *and* unit to that power. In this problem,

Correct: $0.3048 \text{ m} = 1 \text{ ft}$

so $(0.3048)^2 \text{ m}^2 = (1)^2 \text{ ft}^2$ or $0.09290 \text{ m}^2 = 1 \text{ ft}^2$

Incorrect: $0.3048 \text{ m}^2 = 1 \text{ ft}^2$ (squaring only the units and not the numbers)

FOLLOW-UP PROBLEMS

1.9A A landowner wants to spray herbicide on a field that has an area of 2050 m^2 . The herbicide comes in bottles that hold 16 fluid ounces (fl oz), and 1.5 fl oz mixed with 1 gal of water will treat 300 ft^2 . How many bottles of herbicide will the landowner need? Draw a road map to show how you planned the solution.

1.9B From 1946 to 1970, 75,000 kg of mercury was discharged into a lake in New York. The lake has a surface area of 4.5 mi^2 and an average depth of 35 ft. What mass (in g) of mercury is contained in each mL of lake water in 1970? Draw a road map to show how you planned the solution.

Lead	solid	11.3
Gold	solid	19.3

*At room temperature (20°C) and normal atmospheric pressure (1 atm).

Density: A Combination of Units as a Conversion Factor Derived units, combinations of two or more units, can serve as conversion factors (previously we mentioned that speed is length/time). In chemistry, a very important example is **density (d)**, the mass of a sample of a substance divided by its volume (mass/volume ratio):

$$\text{Density} = \frac{\text{mass}}{\text{volume}} \quad (1.5)$$

We isolate each of these variables by treating density as a conversion factor:

$$\text{Mass} = \text{volume} \times \text{density} = \cancel{\text{volume}} \times \frac{\text{mass}}{\cancel{\text{volume}}}$$

or,
$$\text{Volume} = \text{mass} \times \frac{1}{\text{density}} = \cancel{\text{mass}} \times \frac{\text{volume}}{\cancel{\text{mass}}}$$

Because volume can change with temperature, so can density. But, at a given temperature and pressure, the *density of a substance is a characteristic physical property and, thus, has a specific value.*

The SI unit of density is kilograms per cubic meter (kg/m³), but in chemistry, density has units of g/L (g/dm³) or g/mL (g/cm³) (Table 1.7). The densities of gases are much lower than the densities of liquids or solids (see Figure 1.1).

SAMPLE PROBLEM 1.10 | Calculating Density from Mass and Volume

Problem (a) Lithium, a soft, gray solid with the lowest density of any metal, is a key component of advanced batteries, such as the one in your laptop. A slab of lithium weighs 1.49×10^3 mg and has sides that are 20.9 mm by 11.1 mm by 11.9 mm. Find the density of lithium in g/cm³. (b) What is the volume (in mL) of a piece of lithium with a mass of 895 mg?

Plan (a) To find the density in g/cm³, we need the mass of lithium in g and the volume in cm³. The mass is 1.49×10^3 mg, so we convert mg to g. We convert the lengths of the three sides from mm to cm, and then multiply them to find the volume in cm³. Dividing the mass by the volume gives the density (see the road map). (b) We have a known mass of lithium (895 mg); we convert mg to g and then use the density from part (a) as a conversion factor between the mass of lithium in g and its volume in cm³. Finally, we convert cm³ to mL (see the road map).

Solution (a) Converting the mass from mg to g:

$$\text{Mass (g) of lithium} = 1.49 \times 10^3 \cancel{\text{mg}} \left(\frac{10^{-3} \text{ g}}{1 \cancel{\text{mg}}} \right) = 1.49 \text{ g}$$

Converting side lengths from mm to cm:

$$\text{Length (cm) of one side} = 20.9 \cancel{\text{mm}} \times \frac{1 \text{ cm}}{10 \cancel{\text{mm}}} = 2.09 \text{ cm}$$

Similarly, the other side lengths are 1.11 cm and 1.19 cm.

Road Map

Multiplying the sides to get the volume:

$$\text{Volume (cm}^3\text{)} = 2.09 \text{ cm} \times 1.11 \text{ cm} \times 1.19 \text{ cm} = 2.76 \text{ cm}^3$$

Calculating the density:

$$\text{Density of lithium} = \frac{\text{mass}}{\text{volume}} = \frac{1.49 \text{ g}}{2.76 \text{ cm}^3} = 0.540 \text{ g/cm}^3$$

(b) Converting the mass from mg to g:

$$\text{Mass (g) of lithium} = 895 \text{ mg} \times \frac{10^{-3} \text{ g}}{1 \text{ mg}} = 0.895 \text{ g}$$

Converting the mass of lithium to volume (mL):

$$\text{Volume (mL)} = 0.895 \text{ g} \times \frac{1 \text{ cm}^3}{0.540 \text{ g}} \times \frac{1 \text{ mL}}{1 \text{ cm}^3} = 1.66 \text{ mL}$$

Check (a) Since 1 cm = 10 mm, the number of cm in each length should be $\frac{1}{10}$ the number of mm. The units for density are correct, and the size of the answer ($\sim 0.5 \text{ g/cm}^3$) seems correct, since the number of g (1.49) is about half the number of cm^3 (2.76). Also, the problem states that lithium has a very low density, so this answer makes sense.

(b) Since the density of lithium is 0.540 g/cm^3 or 0.540 g/mL , about 0.5 g of lithium has a volume of 1 mL: the volume of a sample of lithium is about twice the value of the mass. Therefore, a mass of about 0.9 g would have a volume of about 1.8 mL.

FOLLOW-UP PROBLEMS

1.10A The density of Venus is similar to that of Earth. The mass of Venus is $4.9 \times 10^{24} \text{ kg}$, and its diameter is 12,100 km. Find the density of Venus in g/cm^3 . The volume of a sphere is given by $\frac{4}{3}\pi r^3$. Draw a road map to show how you planned the solution.

1.10B The volume of aluminum needed to make a soda can is 5.52 cm^3 . The density of aluminum is 2.70 g/cm^3 ; how many soda cans can be made from a block of aluminum that has a mass of 16.2 lb? Draw a road map to show how you planned the solution.

SOME SIMILAR PROBLEMS 1.60–1.63

The mass and volume of the three cubes of copper are different; mass and volume are extensive properties.

For these three cubes of copper,

$$\text{density} = \frac{8.9 \text{ g}}{1.0 \text{ cm}^3} = \frac{71 \text{ g}}{8.0 \text{ cm}^3} = \frac{240 \text{ g}}{27.0 \text{ cm}^3} \approx 8.9 \text{ g/cm}^3$$

The density remains the same regardless of sample size; density is an intensive property.

Figure 1.13 Extensive and intensive properties of matter.

Extensive and Intensive Properties

The variables we measure to study matter fall into two broad categories of properties:

- **Extensive properties** are *dependent* on the amount of substance present; mass and volume, for example, are extensive properties.
- **Intensive properties** are *independent* of the amount of substance; density is an intensive property.

Thus, a gallon of water has four times the mass of a quart of water, but it also has four times the volume, so the density, the *ratio* of mass to volume, is the same for both samples; this concept is illustrated for copper in Figure 1.13. Another important example concerns heat, an extensive property, and temperature, an intensive property: a vat of boiling water has more heat, that is, more energy, than a cup of boiling water, but both samples have the same temperature.

Some intensive properties, like color, melting point, and density, are characteristic of a substance and thus are used to identify it.

Summary of Section 1.5

- › A measured quantity consists of a number and a unit.
- › A conversion factor is a ratio of equivalent quantities (and, thus, equal to 1) that is used to express a quantity in different units.

- › The problem-solving approach used in this book has four parts: (1) plan the steps to the solution, which often includes a flow diagram (road map) of the steps, (2) perform the calculations according to the plan, (3) check to see if the answer makes sense, and (4) practice with similar, follow-up problems and compare your solutions with the ones at the end of the chapter.
- › Density (d), a characteristic physical property of a substance, is the ratio of the mass of a sample to its volume.
- › Extensive properties, such as mass, volume, and energy, depend on the amount of a substance. Intensive properties, such as density and temperature, do not.

CHAPTER REVIEW GUIDE

Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

Understand These Concepts

1. The defining features of the states of matter (§1.1)
2. The distinction between physical and chemical properties and changes (§1.1; SPs 1.1, 1.2)
3. The nature of potential and kinetic energy and their interconversion (§1.1)
4. The process of approaching a phenomenon scientifically and the distinctions among observation, hypothesis, experiment, and model (§1.2)
5. The common units of length, volume, mass, and temperature and their numerical prefixes (§1.3)
6. The distinctions between mass and weight and heat and temperature (§1.3)
7. The meaning of uncertainty in measurements and the use of significant figures and rounding (§1.4)

8. The distinctions between accuracy and precision and between systematic and random error (§1.4)
9. The distinction between intensive and extensive properties (§1.5)

Master These Skills

1. Converting among the Kelvin, Celsius, and Fahrenheit scales (SP 1.3)
2. Determining the number of significant figures (SP 1.4) and rounding to the correct number of digits (SP 1.5)
3. Using conversion factors in calculations and a systematic approach of plan, solution, check, and follow-up for solving problems (§1.5; SPs 1.6–1.9)
4. Finding density from mass and volume (SP 1.10)

Key Terms

Page numbers appear in parentheses.

accuracy (22)	derived unit (11)	liter (L) (13)	scientific method (10)
base (fundamental) unit (11)	dimensional analysis (23)	mass (14)	second (s) (14)
calibration (23)	energy (8)	matter (3)	SI unit (11)
Celsius scale (16)	exact number (21)	meter (m) (12)	significant figures (18)
chemical change (chemical reaction) (5)	experiment (10)	milliliter (mL) (13)	solid (3)
chemical property (5)	extensive property (30)	model (theory) (10)	state of matter (3)
chemistry (3)	gas (3)	natural law (10)	systematic error (22)
combustion (10)	heat (15)	observation (10)	temperature (T) (15)
composition (3)	hypothesis (10)	physical change (4)	thermometer (15)
controlled experiment (10)	intensive property (30)	physical property (4)	uncertainty (18)
conversion factor (23)	Kelvin (absolute) scale (16)	potential energy (8)	variable (10)
cubic meter (m^3) (13)	kelvin (K) (15)	precision (22)	volume (V) (13)
data (10)	kilogram (kg) (14)	property (4)	weight (14)
density (d) (29)	kinetic energy (8)	random error (22)	
	liquid (3)	round off (20)	

Key Equations and Relationships

Page numbers appear in parentheses.

- 1.1** Converting temperature from $^{\circ}\text{C}$ to K (16):

$$T(\text{in K}) = T(\text{in } ^{\circ}\text{C}) + 273.15$$
- 1.2** Converting temperature from K to $^{\circ}\text{C}$ (16):

$$T(\text{in } ^{\circ}\text{C}) = T(\text{in K}) - 273.15$$
- 1.3** Converting temperature from $^{\circ}\text{C}$ to $^{\circ}\text{F}$ (17):

$$T(\text{in } ^{\circ}\text{F}) = \frac{9}{5} T(\text{in } ^{\circ}\text{C}) + 32$$

- 1.4** Converting temperature from $^{\circ}\text{F}$ to $^{\circ}\text{C}$ (17):

$$T(\text{in } ^{\circ}\text{C}) = [T(\text{in } ^{\circ}\text{F}) - 32] \frac{5}{9}$$
- 1.5** Calculating density from mass and volume (29):

$$\text{Density} = \frac{\text{mass}}{\text{volume}}$$

CHAPTER PRACTICE TEST

The answers to the Practice Test problems are shown below and the full solutions can be found in the e-book.

1. Carry out the following calculation and report the answer to the correct number of significant figures.

$$1.68 \left(\frac{23.50 - 2.3}{1.248 \times 10^3} \right)$$

- (a) 0.03 (b) 0.029 (c) 0.0285
(d) 0.02854 (e) 0.028538

2. The density of aluminum is 2.70 g/cm^3 . What volume (in liters) is occupied by 15.5 lb of aluminum?

- (a) 5.74 L (b) 3.84 L (c) 2.60 L
(d) 19.0 L (e) 1.68 L

3. Which **two** of the following values have exactly three significant figures? Select **both** correct answers.

- (a) 960 (b) 0.0120 (c) 723.0
(d) 0.082 (e) 0.006 (f) 5.20×10^5

4. Convert 2.34×10^{22} picograms to megagrams.

- (a) $2.34 \times 10^4 \text{ Mg}$ (b) $2.34 \times 10^7 \text{ Mg}$ (c) $2.34 \times 10^{16} \text{ Mg}$
(d) $2.34 \times 10^{-6} \text{ Mg}$ (e) $2.34 \times 10^{13} \text{ Mg}$ (f) $2.34 \times 10^{-8} \text{ Mg}$

5. Using a graduated cylinder and a balance, four students each determine the density of a liquid four times. The results, in g/mL, are:

Student I	0.62, 0.63, 0.61, 0.62	Average: 0.62 g/mL
Student II	0.78, 0.82, 0.81, 0.79	Average: 0.80 g/mL
Student III	0.88, 0.89, 0.90, 0.89	Average: 0.89 g/mL
Student IV	0.72, 0.88, 0.70, 0.90	Average: 0.80 g/mL

Given that the true density of the liquid is 0.80 g/mL , which **two** of the following statements are correct? Select **both** correct answers.

- (a) A systematic error is evident in the results obtained by Students II and IV.
(b) For the results obtained by Student I, precision was good but accuracy was poor.
(c) Considering *both* accuracy and precision, Student IV had the best results.
(d) The data of all four students contain random error.
(e) The results obtained by Student II had the poorest precision.

6. If the fuel efficiency of a car is 22 miles per gallon, what is its fuel efficiency in kilometers per liter?

- (a) 940 km/L (b) 17 km/L (c) 37 km/L
(d) 5.7 km/L (e) 19 km/L (f) 9.4 km/L

7. The melting point of iron is $2800.^\circ\text{F}$. What is this temperature in kelvins?

- (a) 1538 K (b) 1811 K (c) 5345 K
(d) 1265 K (e) 1846 K

8. A 12-ounce cola drink is advertised as having 34 mg of caffeine. What mass (in grams) of caffeine is in a 2.0-L bottle of this soda?

- (a) 0.24 g (b) 0.35 g (c) 0.19 g
(d) 0.11 g (e) 0.27 g

9. The density of platinum metal is 21.5 g/cm^3 . Express this density in lb/ft^3 .

- (a) 1.44 lb/ft^3 (b) 208 lb/ft^3 (c) 1510 lb/ft^3
(d) 1340 lb/ft^3 (e) 784 lb/ft^3

10. A student has a fish aquarium that is 24 inches long and 13 inches wide. How many liters of water are needed to fill the aquarium to a depth of 10. inches?

- (a) 7.9 L (b) 110 L (c) 42 L
(d) 34 L (e) 51 L

Answers: 1. c; 2. c; 3. b, f; 4. a; 5. b, d; 6. f; 7. b; 8. c; 9. d; 10. e

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

1.1A Chemical. The red-and-blue and separate red particles on the left become paired red and separate blue particles on the right.

1.1B Physical. The red particles are the same on the right and on the left, but they have changed from being close together in the solid state to being far apart in the gaseous state.

1.2A (a) Physical. Solid iodine changes to gaseous iodine.
(b) Chemical. Gasoline burns in air to form different substances.
(c) Chemical. In contact with air, substances in torn skin and blood react to form different substances.

1.2B (a) Physical. Gaseous water (water vapor) changes to droplets of liquid water. (b) Chemical. Different substances are formed in the milk that give it a sour taste. (c) Physical. Solid butter changes to a liquid.

1.3A $T (\text{in } ^\circ\text{C}) = 234 \text{ K} - 273.15 = -39^\circ\text{C}$
 $T (\text{in } ^\circ\text{F}) = \frac{9}{5}(-39^\circ\text{C}) + 32 = -38^\circ\text{F}$

Answers contains two significant figures (see Section 1.4).

1.3B $T (\text{in } ^\circ\text{C}) = (2325^\circ\text{F} - 32) \frac{5}{9} = 1274^\circ\text{C}$
 $T (\text{in } ^\circ\text{K}) = 1274^\circ\text{C} + 273.15 = 1547 \text{ K}$

1.4A (a) 31.070 mg , 5 sf
(b) 0.06060 g , 4 sf
(c) $850.^\circ\text{C}$, 3 sf

1.4B (a) $2.000 \times 10^2 \text{ mL}$, 4 sf
(b) $3.90 \times 10^{-6} \text{ m}$, 3 sf
(c) $4.01 \times 10^{-4} \text{ L}$, 3 sf

1.5A $\frac{45.61 \text{ mL} + 62.3 \text{ mL}}{73.55 \text{ s}} = \frac{107.9}{73.55} = 1.467 \text{ mL/s}$

1.5B $\frac{154.64 \text{ g} - 35.26 \text{ g}}{4.20 \text{ cm} \times 5.12 \text{ cm} \times 6.752 \text{ cm}} = \frac{119.38}{145} = 0.823 \text{ g/cm}^3$

1.6A The known quantity is 10,500 m; start the problem with this value. Use the conversion factor 1 mi/15 min to convert distance in miles to time in minutes.

Time (min)

$$= 10,500 \cancel{\text{m}} \times \frac{1 \cancel{\text{km}}}{1000 \cancel{\text{m}}} \times \frac{1 \cancel{\text{mi}}}{1.6093 \cancel{\text{km}}} \times \frac{15 \text{ min}}{1 \cancel{\text{mi}}} = 98 \text{ min}$$

See Road Map 1.6A.

1.6B Start the problem with the given quantity of 1.0 in; use the conversion factor 1 virus particle/30 nm to convert from length in nm to number of virus particles.

No. of virus particles

$$= 1.0 \text{ in} \times \frac{2.54 \text{ cm}}{1 \text{ in}} \times \frac{1 \text{ m}}{100 \text{ cm}} \times \frac{1 \times 10^9 \text{ nm}}{1 \text{ m}} \times \frac{1 \text{ virus particle}}{30 \text{ nm}}$$

$$= 8.5 \times 10^5 \text{ virus particles}$$

See Road Map 1.6B.

Road Map 1.6A

Road Map 1.6B

1.7A Radius of ribosome (dm) = $\frac{21.4 \text{ nm}}{2} \times \frac{1 \text{ m}}{10^9 \text{ nm}} \times \frac{10 \text{ dm}}{1 \text{ m}}$

$$= 1.07 \times 10^{-7} \text{ dm}$$

Volume of ribosome (dm³) = $\frac{4}{3}\pi r^3 = \frac{4}{3}(3.14)(1.07 \times 10^{-7} \text{ dm})^3$

$$= 5.13 \times 10^{-21} \text{ dm}^3$$

Volume of ribosome (μL)

$$= (5.13 \times 10^{-21} \text{ dm}^3) \left(\frac{1 \text{ L}}{1 \text{ dm}^3} \right) \left(\frac{10^6 \text{ μL}}{1 \text{ L}} \right)$$

$$= 5.13 \times 10^{-15} \text{ μL}$$

See Road Map 1.7A.

1.7B Volume (L) = $8400 \text{ gal} \times \frac{3.7854 \text{ dm}^3}{1 \text{ gal}} \times \frac{1 \text{ L}}{1 \text{ dm}^3}$

$$= 32,000 \text{ L}$$

See Road Map 1.7B.

Road Map 1.7A

Road Map 1.7B

1.8A Start the problem with the given value of 8.0 h. The conversion factors are constructed from the equivalent quantities given in the problem: 1 s = 1.5 drops; 1 drop = 65 mg.

Mass (kg) of solution

$$= 8.0 \text{ h} \times \frac{60 \text{ min}}{1 \text{ h}} \times \frac{60 \text{ s}}{1 \text{ min}} \times \frac{1.5 \text{ drops}}{1 \text{ s}}$$

$$\times \frac{65 \text{ mg}}{1 \text{ drop}} \times \frac{1 \text{ g}}{10^3 \text{ mg}} \times \frac{1 \text{ kg}}{10^3 \text{ g}}$$

$$= 2.8 \text{ kg}$$

See Road Map 1.8A.

1.8B Start the problem with the given quantity of 3.25 kg of apples. The conversion factors are constructed from the equivalent quantities given in the problem: 1 lb = 3 apples; 1 apple = 159 mg potassium.

$$\text{Mass (g)} = 3.25 \text{ kg} \times \frac{1 \text{ lb}}{0.4536 \text{ kg}}$$

$$\times \frac{3 \text{ apples}}{1 \text{ lb}} \times \frac{159 \text{ mg potassium}}{1 \text{ apple}} \times \frac{1 \text{ g}}{10^3 \text{ mg}}$$

$$= 3.42 \text{ g potassium}$$

See Road Map 1.8B.

Road Map 1.8A

Road Map 1.8B

1.9A Start the problem with the given value of 2050 m². The conversion factors are constructed from 300 ft² = 1.5 fl oz and 16 fl oz = 1 bottle.

$$\text{Number of bottles} = 2050 \text{ m}^2 \times \frac{1 \text{ ft}^2}{(0.3048)^2 \text{ m}^2} \times \frac{1.5 \text{ fl oz}}{300 \text{ ft}^2}$$

$$\times \frac{1 \text{ bottle}}{16 \text{ fl oz}}$$

$$= 7 \text{ bottles}$$

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS (continued)

$$\mathbf{1.9B} \text{ Mass (g)} = 75,000 \text{ kg} \times \frac{1000 \text{ g}}{1 \text{ kg}} = 7.5 \times 10^7 \text{ g}$$

$$\begin{aligned} \text{Volume (mL)} &= 4.5 \text{ mi}^2 \times \frac{(5280)^2 \text{ ft}^2}{1 \text{ mi}^2} \times 35 \text{ ft} \times \frac{(0.3048)^3 \text{ m}^3}{1 \text{ ft}^3} \\ &\quad \times \frac{(100)^3 \text{ cm}^3}{1 \text{ m}^3} \times \frac{1 \text{ mL}}{1 \text{ cm}^3} \\ &= 1.2 \times 10^{14} \text{ mL} \end{aligned}$$

$$\begin{aligned} \text{Mass (g) of mercury per mL} &= \frac{7.5 \times 10^7 \text{ g}}{1.2 \times 10^{14} \text{ mL}} \\ &= 6.2 \times 10^{-7} \text{ g/mL} \end{aligned}$$

$$\mathbf{1.10A} \text{ Mass (g)} = 4.9 \times 10^{24} \text{ kg} \times \frac{10^3 \text{ g}}{1 \text{ kg}} = 4.9 \times 10^{27} \text{ g}$$

$$\text{Radius (cm)} = \frac{12,100 \text{ km}}{2} \times \frac{10^3 \text{ m}}{1 \text{ km}} \times \frac{10^2 \text{ cm}}{1 \text{ m}} = 6.05 \times 10^8 \text{ cm}$$

$$\begin{aligned} \text{Volume (cm}^3\text{)} &= \frac{4}{3}\pi r^3 = \frac{4}{3}(3.14)(6.05 \times 10^8 \text{ cm})^3 \\ &= 9.27 \times 10^{26} \text{ cm}^3 \end{aligned}$$

$$\text{Density (g/cm}^3\text{)} = \frac{4.9 \times 10^{27} \text{ g}}{9.27 \times 10^{26} \text{ cm}^3} = 5.3 \text{ g/cm}^3$$

See Road Map 1.10A.

$$\begin{aligned} \mathbf{1.10B} \text{ Number of cans} &= 16.2 \text{ H} \times \frac{453.6 \text{ g}}{1 \text{ H}} \times \frac{1 \text{ cm}^3}{2.70 \text{ g}} \times \frac{1 \text{ can}}{5.52 \text{ cm}^3} \\ &= 493 \text{ cans} \end{aligned}$$

See Road Map 1.10B.

Road Map 1.10A

Road Map 1.10B

PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section.

Some Fundamental Definitions

(Sample Problems 1.1 and 1.2)

Concept Review Question

1.1 Scenes A–D represent atomic-scale views of different samples of substances:

- Under one set of conditions, the substances in A and B mix, and the result is depicted in C. Does this represent a chemical or a physical change?
- Under a second set of conditions, the same substances mix, and the result is depicted in D. Does this represent a chemical or a physical change?
- Under a third set of conditions, the sample depicted in C changes to that in D. Does this represent a chemical or a physical change?
- After the change in part (c) has occurred, does the sample have different chemical properties? Physical properties?

Skill-Building Exercises (grouped in similar pairs)

1.2 Describe solids, liquids, and gases in terms of how they fill a container. Use your descriptions to identify the physical state (at room temperature) of the following: (a) helium in a toy balloon; (b) mercury in a thermometer; (c) soup in a bowl.

1.3 Use your descriptions from Problem 1.2 to identify the physical state (at room temperature) of the following: (a) the air in your room; (b) tablets in a bottle of vitamins; (c) sugar in a packet.

1.4 Define *physical property* and *chemical property*. Identify each type of property in the following statements:

- Yellow-green chlorine gas attacks silvery sodium metal to form white crystals of sodium chloride (table salt).
- A magnet separates a mixture of black iron shavings and white sand.

1.5 Define *physical change* and *chemical change*. State which type of change occurs in each of the following statements:

- Passing an electric current through molten magnesium chloride yields molten magnesium and gaseous chlorine.
- The iron in discarded automobiles slowly forms reddish brown, crumbly rust.

1.6 Which of the following is a chemical change? Explain your reasoning: (a) boiling canned soup; (b) toasting a slice of bread; (c) chopping a log; (d) burning a log.

1.7 Which of the following changes can be reversed by changing the temperature: (a) dew condensing on a leaf; (b) an egg turning hard when it is boiled; (c) ice cream melting; (d) a spoonful of batter cooking on a hot griddle?

1.8 For each pair, which has higher potential energy?

- The fuel in your car or the gaseous products in its exhaust
- Wood in a fire or the ashes after the wood burns

1.9 For each pair, which has higher kinetic energy?

- A sled resting at the top of a hill or a sled sliding down the hill
- Water above a dam or water falling over the dam

The Scientific Approach: Developing a Model

Concept Review Questions

1.10 How are the key elements of scientific thinking used in the following scenario? While making toast, you notice it fails to pop out of the toaster. Thinking the spring mechanism is stuck, you notice that the bread is unchanged. Assuming you forgot to plug in the toaster, you check and find it is plugged in. When you take the toaster into the dining room and plug it into a different outlet, you find the toaster works. Returning to the kitchen, you turn on the switch for the overhead light and nothing happens.

1.11 Why is a quantitative observation more useful than a non-quantitative one? Which of the following is (are) quantitative? (a) The Sun rises in the east. (b) A person weighs one-sixth as much on the Moon as on Earth. (c) Ice floats on water. (d) A hand pump cannot draw water from a well more than 34 ft deep.

1.12 Describe the essential features of a well-designed experiment.

1.13 Describe the essential features of a scientific model.

Units of Measurement

(Sample Problem 1.3)

Concept Review Questions

1.14 Explain the difference between mass and weight. Why is your weight on the Moon one-sixth that on Earth?

1.15 Explain the difference between heat and temperature. Does 1 L of water at 65°F have more, less, or the same quantity of energy as 1 L of water at 65°C?

1.16 A one-step conversion is sufficient to convert a temperature in the Celsius scale to the Kelvin scale, but not to the Fahrenheit scale. Explain.

Skill-Building Exercises (grouped in similar pairs)

1.17 Perform the following conversions:

- 68°F (a pleasant spring day) to °C and K
- −164°C (the boiling point of methane, the main component of natural gas) to K and °F
- 0 K (absolute zero, theoretically the coldest possible temperature) to °C and °F

1.18 Perform the following conversions:

- 106°F (the body temperature of many birds) to K and °C
- 3410°C (the melting point of tungsten, the highest for any metallic element) to K and °F
- 6.1×10^3 K (the surface temperature of the Sun) to °F and °C

Uncertainty in Measurement: Significant Figures

(Sample Problems 1.4 and 1.5)

Concept Review Questions**1.19** What is an exact number? How are exact numbers treated differently from other numbers in a calculation?**1.20** Which procedure(s) decrease(s) the random error of a measurement: (1) taking the average of more measurements; (2) calibrating the instrument; (3) taking fewer measurements? Explain.**1.21** A newspaper reported that the attendance at Slippery Rock's home football game was 16,532. (a) How many significant figures does this number contain? (b) Was the actual number of people counted? (c) After Slippery Rock's next home game, the newspaper reported an attendance of 15,000. If you assume that this number contains two significant figures, how many people could actually have been at the game?**Skill-Building Exercises (grouped in similar pairs)****1.22** Underline the significant zeros in the following numbers: (a) 0.41; (b) 0.041; (c) 0.0410; (d) 4.0100×10^4 .**1.23** Underline the significant zeros in the following numbers: (a) 5.08; (b) 508; (c) 5.080×10^3 ; (d) 0.05080.**1.24** Round off each number to the indicated number of significant figures (sf): (a) 0.0003554 (to 2 sf); (b) 35.8348 (to 4 sf); (c) 22.4555 (to 3 sf).**1.25** Round off each number to the indicated number of significant figures (sf): (a) 231.554 (to 4 sf); (b) 0.00845 (to 2 sf); (c) 144,000 (to 2 sf).**1.26** Round off each number in the following calculation to one fewer significant figure, and find the answer:

$$\frac{19 \times 155 \times 8.3}{3.2 \times 2.9 \times 4.7}$$

1.27 Round off each number in the following calculation to one fewer significant figure, and find the answer:

$$\frac{10.8 \times 6.18 \times 2.381}{24.3 \times 1.8 \times 19.5}$$

1.28 Carry out the following calculations, making sure that your answer has the correct number of significant figures:

(a) $\frac{2.795 \text{ m} \times 3.10 \text{ m}}{6.48 \text{ m}}$

(b) $V = \frac{4}{3}\pi r^3$, where $r = 17.282 \text{ mm}$

(c) $1.110 \text{ cm} + 17.3 \text{ cm} + 108.2 \text{ cm} + 316 \text{ cm}$

1.29 Carry out the following calculations, making sure that your answer has the correct number of significant figures:

(a) $\frac{2.420 \text{ g} + 15.6 \text{ g}}{4.8 \text{ g}}$ (b) $\frac{7.87 \text{ mL}}{16.1 \text{ mL} - 8.44 \text{ mL}}$

(c) $V = \pi r^2 h$, where $r = 6.23 \text{ cm}$ and $h = 4.630 \text{ cm}$

1.30 Write the following numbers in scientific notation: (a) 131,000.0; (b) 0.00047; (c) 210,006; (d) 2160.5.**1.31** Write the following numbers in scientific notation: (a) 282.0; (b) 0.0380; (c) 4270.8; (d) 58,200.9.**1.32** Write the following numbers in standard notation. Use a terminal decimal point when needed.

(a) 5.55×10^3 ; (b) 1.0070×10^4 ; (c) 8.85×10^{-7} ; (d) 3.004×10^{-3} .

1.33 Write the following numbers in standard notation. Use a terminal decimal point when needed.

(a) 6.500×10^3 ; (b) 3.46×10^{-5} ; (c) 7.5×10^2 ; (d) 1.8856×10^2 .

1.34 Convert the following into correct scientific notation:

(a) 802.5×10^2 ; (b) 1009.8×10^{-6} ; (c) 0.077×10^{-9} .

1.35 Convert the following into correct scientific notation:

(a) 14.3×10^1 ; (b) 851×10^{-2} ; (c) 7500×10^{-3} .

1.36 Carry out each calculation, paying special attention to significant figures, rounding, and units (J = joule, the SI unit of energy; mol = mole, the SI unit for amount of substance):

(a) $\frac{(6.626 \times 10^{-34} \text{ J} \cdot \text{s})(2.9979 \times 10^8 \text{ m/s})}{489 \times 10^{-9} \text{ m}}$

(b) $\frac{(6.022 \times 10^{23} \text{ molecules/mol})(1.23 \times 10^2 \text{ g})}{46.07 \text{ g/mol}}$

(c) $(6.022 \times 10^{23} \text{ atoms/mol})(1.28 \times 10^{-18} \text{ J/atom}) \left(\frac{1}{2^2} - \frac{1}{3^2} \right)$, where the numbers 2 and 3 in the last term are exact

1.37 Carry out each calculation, paying special attention to significant figures, rounding, and units:

(a) $\frac{4.32 \times 10^7 \text{ g}}{\frac{4}{3}(3.1416)(1.95 \times 10^2 \text{ cm})^3}$ (The term $\frac{4}{3}$ is exact.)

(b) $\frac{(1.84 \times 10^2 \text{ g})(44.7 \text{ m/s})^2}{2}$ (The term 2 is exact.)

(c) $\frac{(1.07 \times 10^{-4} \text{ mol/L})^2(3.8 \times 10^{-3} \text{ mol/L})}{(8.35 \times 10^{-5} \text{ mol/L})(1.48 \times 10^{-2} \text{ mol/L})^3}$

1.38 Which statements include exact numbers?

- (a) Angel Falls is 3212 ft high.
 (b) There are 8 known planets in the Solar System.
 (c) There are 453.59 g in 1 lb.
 (d) There are 1000 mm in 1 m.

1.39 Which of the following include exact numbers?

- (a) The speed of light in a vacuum is a physical constant; to six significant figures, it is $2.99792 \times 10^8 \text{ m/s}$.
 (b) The density of mercury at 25°C is 13.53 g/mL .
 (c) There are 3600 s in 1 h.
 (d) In 2018, the United States had 50 states.

Problems in Context**1.40** How long is the metal strip shown below? Be sure to answer with the correct number of significant figures.**1.41** A laboratory instructor gives a sample of amino-acid powder to each of four students, I, II, III, and IV, and they weigh the samples. The true value is 8.72 g. Their results for three trials are
 I: 8.72 g, 8.74 g, 8.70 g II: 8.56 g, 8.77 g, 8.83 g
 III: 8.50 g, 8.48 g, 8.51 g IV: 8.41 g, 8.72 g, 8.55 g

- (a) Calculate the average mass from each set of data and tell which set is the most accurate.
 (b) Precision is a measure of the average of the deviations of each piece of data from the average value. Which set of data is the most precise? Is this set also the most accurate?
 (c) Which set of data is both the most accurate and the most precise?
 (d) Which set of data is both the least accurate and the least precise?

1.42 The following dartboards illustrate the types of errors often seen in measurements. The bull's-eye represents the actual value, and the darts represent the data.

- (a) Which experiments yield the same average result?
 (b) Which experiment(s) display(s) high precision?
 (c) Which experiment(s) display(s) high accuracy?
 (d) Which experiment(s) show(s) a systematic error?

Unit and Conversion Factors in Calculations

(Sample Problems 1.6–1.10)

Concept Review Questions

- 1.43** When you convert feet to inches, how do you decide which part of the conversion factor should be in the numerator and which in the denominator?
1.44 For each of the following cases, state whether the density of the object increases, decreases, or remains the same:
 (a) A sample of chlorine gas is compressed.
 (b) A lead weight is carried up a high mountain.
 (c) A sample of water is frozen.
 (d) An iron bar is cooled.
 (e) A diamond is submerged in water.
1.45 Describe the difference between intensive and extensive properties. Which of the following properties are intensive: (a) mass; (b) density; (c) volume; (d) melting point?

Skill-Building Exercises (grouped in similar pairs)

- 1.46** Write the conversion factor(s) for
 (a) in^2 to m^2 (b) km^2 to cm^2
 (c) mi/h to m/s (d) lb/ft^3 to g/cm^3
1.47 Write the conversion factor(s) for
 (a) cm/min to in/s (b) m^3 to in^3
 (c) m/s^2 to km/h^2 (d) gal/h to L/min
1.48 The average radius of a molecule of lysozyme, an enzyme in tears, is 1430 pm. What is its radius in nanometers (nm)?
1.49 The radius of a barium atom is 2.22×10^{-10} m. What is its radius in angstroms (Å)?
1.50 What is the length in inches (in) of a 100.-m soccer field?
1.51 The center on your school's basketball team is 6 ft 10 in tall. How tall is the player in millimeters (mm)?

1.52 A small hole in the wing of a space shuttle requires a 20.7-cm^2 patch. (a) What is the patch's area in square kilometers (km^2)? (b) If the patching material costs NASA $\$3.25/\text{in}^2$, what is the cost of the patch?

1.53 The area of a telescope lens is 7903 mm^2 . (a) What is the area in square feet (ft^2)? (b) If it takes a technician 45 s to polish 135 mm^2 , how long does it take her to polish the entire lens?

1.54 A particular cell phone model has a mass of 6.14 oz (16 oz = 1 lb). Express this mass in grams.

1.55 There are 2.60×10^{15} short tons of oxygen in the atmosphere (1 short ton = 2000 lb). How many metric tons of oxygen are present in the atmosphere (1 metric ton = 1000 kg)?

1.56 The average density of Earth is 5.52 g/cm^3 . What is its density in (a) kg/m^3 ; (b) lb/ft^3 ?

1.57 The speed of light in a vacuum is $2.998 \times 10^8\text{ m/s}$. What is its speed in (a) km/h ; (b) mi/min ?

1.58 The volume of a certain bacterial cell is $2.56\text{ }\mu\text{m}^3$. (a) What is its volume in cubic millimeters (mm^3)? (b) What is the volume of 10^5 cells in liters (L)?

1.59 (a) How many cubic meters of milk are in 1 qt (946.4 mL)? (b) How many liters of milk are in 835 gal (1 gal = 4 qt)?

1.60 An empty vial has a mass of 55.32 g. (a) If the mass of the vial is 185.56 g when filled with liquid mercury ($d = 13.53\text{ g/cm}^3$), what volume of mercury is in the vial? (b) What would the mass of the vial be if it were filled with the same volume of water ($d = 0.997\text{ g/cm}^3$ at 25°C)?

1.61 An empty Erlenmeyer flask has a mass of 241.3 g. When filled with water ($d = 1.00\text{ g/cm}^3$), the flask and its contents have a mass of 489.1 g. (a) What is the volume of water in the flask? (b) What is the mass of the flask when filled with the same volume of chloroform ($d = 1.48\text{ g/cm}^3$)?

1.62 A small cube of aluminum measures 15.6 mm on a side and has a mass of 10.25 g. What is the density of aluminum in g/cm^3 ?

1.63 A steel ball-bearing with a circumference of 32.5 mm has a mass of 4.20 g. What is the density of the steel in g/cm^3 (V of a sphere = $\frac{4}{3}\pi r^3$; circumference of a circle = $2\pi r$)?

Problems in Context

1.64 A 25.0-g sample of each of three unknown metals is added to 25.0 mL of water in graduated cylinders A, B, and C, and the final volumes are depicted in the following circles. Given their densities, identify the metal in each cylinder: zinc (7.14 g/mL), iron (7.87 g/mL), or nickel (8.91 g/mL).

1.65 The distance between two adjacent peaks on a wave is called the *wavelength*.

- (a) The wavelength of a beam of ultraviolet light is 247 nanometers (nm). What is its wavelength in meters?
 (b) The wavelength of a beam of red light is 6760 pm. What is its wavelength in angstroms (Å)?

1.66 Each of the beakers depicted below contains two liquids that do not dissolve in each other. Three of the liquids are designated A, B, and C, and water is designated W.

(a) Which of the liquids is (are) more dense than water and less dense than water?

(b) If the densities of W, C, and A are 1.0 g/mL, 0.88 g/mL, and 1.4 g/mL, respectively, which of the following densities is possible for liquid B: 0.79 g/mL, 0.86 g/mL, 0.94 g/mL, or 1.2 g/mL?

1.67 A cylindrical tube 9.5 cm high and 0.85 cm in diameter is used to collect blood samples. How many cubic decimeters (dm^3) of blood can it hold (V of a cylinder = $\pi r^2 h$)?

1.68 Copper can be drawn into thin wires. How many meters of 34-gauge wire (diameter = 6.304×10^{-3} in) can be produced from the copper in 5.01 lb of covellite, an ore of copper that is 66% copper by mass? (*Hint*: Treat the wire as a cylinder: V of cylinder = $\pi r^2 h$; d of copper = 8.95 g/cm^3 .)

1.69 These organic solvents are used to clean compact discs:

Solvent	Density (g/mL) at 20°C
Chloroform	1.492
Diethyl ether	0.714
Ethanol	0.789
Isopropanol	0.785
Toluene	0.867

(a) If a 15.00-mL sample of CD cleaner weighs 11.775 g at 20°C, which solvent does the sample most likely contain?

(b) The chemist analyzing the cleaner calibrates her equipment and finds that the pipet is accurate to $\pm 0.02 \text{ mL}$, and the balance is accurate to $\pm 0.003 \text{ g}$. Is this equipment precise enough to distinguish between ethanol and isopropanol?

Comprehensive Problems

1.70 Two blank potential energy diagrams appear below. Beneath each diagram are objects to place in the diagram. Draw the objects on the dashed lines to indicate higher or lower potential energy and label each case as more or less stable:

1.71 The scenes below illustrate two different mixtures. When mixture A at 273 K is heated to 473 K, mixture B results.

(a) How many different chemical changes occur?

(b) How many different physical changes occur?

1.72 Bromine is used to prepare the pesticide methyl bromide and flame retardants for plastic electronic housings. It is recovered from seawater, underground brines, and the Dead Sea. The average concentrations of bromine in seawater ($d = 1.024 \text{ g/mL}$) and the Dead Sea ($d = 1.22 \text{ g/mL}$) are 0.065 g/L and 0.50 g/L, respectively. What is the mass ratio of bromine in the Dead Sea to that in seawater?

1.73 An Olympic-size pool is 50.0 m long and 25.0 m wide.

(a) How many gallons of water ($d = 1.0 \text{ g/mL}$) are needed to fill the pool to an average depth of 4.8 ft? (b) What is the mass (in kg) of water in the pool?

1.74 At room temperature (20°C) and pressure, the density of air is 1.189 g/L. An object will float in air if its density is less than that of air. In a buoyancy experiment with a new plastic, a chemist creates a rigid, thin-walled ball with a mass of 0.12 g and a volume of 560 cm^3 .

(a) Will the ball float if it is evacuated?

(b) Will it float if filled with carbon dioxide ($d = 1.830 \text{ g/L}$)?

(c) Will it float if filled with hydrogen ($d = 0.0899 \text{ g/L}$)?

(d) Will it float if filled with oxygen ($d = 1.330 \text{ g/L}$)?

(e) Will it float if filled with nitrogen ($d = 1.165 \text{ g/L}$)?

(f) For any case in which the ball will float, how much weight must be added to make it sink?

1.75 Asbestos is a fibrous silicate mineral with remarkably high tensile strength. But it is no longer used because airborne asbestos particles can cause lung cancer. Grunerite, a type of asbestos, has a tensile strength of $3.5 \times 10^2 \text{ kg/mm}^2$ (thus, a strand of grunerite with a 1-mm^2 cross-sectional area can hold up to $3.5 \times 10^2 \text{ kg}$). The tensile strengths of aluminum and Steel No. 5137 are $2.5 \times 10^4 \text{ lb/in}^2$ and $5.0 \times 10^4 \text{ lb/in}^2$, respectively. Calculate the cross-sectional areas (in mm^2) of wires of aluminum and of Steel No. 5137 that have the same tensile strength as a fiber of grunerite with a cross-sectional area of $1.0 \mu\text{m}^2$.

1.76 Earth's oceans have an average depth of 3800 m, a total surface area of $3.63 \times 10^8 \text{ km}^2$, and an average concentration of dissolved gold of $5.8 \times 10^{-9} \text{ g/L}$. (a) How many grams of gold are in the oceans? (b) How many cubic meters of gold are in the oceans? (c) Assuming the price of gold is \$1595/troy oz, what is the value of gold in the oceans (1 troy oz = 31.1 g; d of gold = 19.3 g/cm^3)?

1.77 Brass is an alloy of copper and zinc. Varying the mass percentages of the two metals produces brasses with different properties. A brass called *yellow zinc* has high ductility and strength and is 34–37% zinc by mass. (a) Find the mass range (in g) of copper in 185 g of yellow zinc. (b) What is the mass range (in g) of zinc in a sample of yellow zinc that contains 46.5 g of copper?

1.78 Liquid nitrogen is obtained from liquefied air and is used industrially to prepare frozen foods. It boils at 77.36 K. (a) What

is this temperature in $^{\circ}\text{C}$? (b) What is this temperature in $^{\circ}\text{F}$? (c) At the boiling point, the density of the liquid is 809 g/L and that of the gas is 4.566 g/L. How many liters of liquid nitrogen are produced when 895.0 L of nitrogen gas is liquefied at 77.36 K?

1.79 A jogger runs at an average speed of 5.9 mi/h. (a) How fast is she running in m/s? (b) How many kilometers does she run in 98 min? (c) If she starts a run at 11:15 am, what time is it after she covers 4.75×10^4 ft?

1.80 Scenes A and B depict changes in matter at the atomic scale:

- (a) Which show(s) a physical change?
- (b) Which show(s) a chemical change?
- (c) Which result(s) in different physical properties?
- (d) Which result(s) in different chemical properties?
- (e) Which result(s) in a change in state?

1.81 If a temperature scale were based on the freezing point (5.5°C) and boiling point (80.1°C) of benzene and the temperature difference between these points were divided into 50 units (called $^{\circ}\text{X}$), what would be the freezing and boiling points of water in $^{\circ}\text{X}$? (See Figure 1.9.)

1.82 Earth's surface area is $5.10 \times 10^8 \text{ km}^2$; its crust has a mean thickness of 35 km and a mean density of 2.8 g/cm^3 . The two most abundant elements in the crust are oxygen ($4.55 \times 10^5 \text{ g/t}$, where t stands for "metric ton"; $1 \text{ t} = 1000 \text{ kg}$) and silicon ($2.72 \times 10^5 \text{ g/t}$), and the two rarest nonradioactive elements are ruthenium and rhodium, each with an abundance of $1 \times 10^{-4} \text{ g/t}$. What is the total mass of each of these elements in Earth's crust?

The simple “lead” pencil does not actually contain lead! Instead, a form of carbon known as graphite is responsible for the pencil marks we make on paper. The graphite pencil tip is composed of stacked flat sheets of carbon atoms that are arranged in rings, an arrangement that looks like chicken wire (*photo*). The carbon sheets can slide past each other, depositing atoms of carbon from the pencil tip to the paper. Atoms not only make up our pencil doodles—atoms are the ultimate particles that make up all things.

The first record of an atomic theory of matter dates back to ancient Greece when the Greek philosopher Democritus (c. 460–370 BC) reasoned that if matter, such as a piece of aluminum foil, were cut into smaller and smaller pieces, there would eventually be a particle of aluminum so small that it could no longer be cut. Therefore, matter is ultimately composed of indivisible particles with nothing but empty space between them. He called the particles *atoms* (Greek *atomos*, “indivisible”). This revolutionary idea about matter was suppressed for 2000 years because the influential philosopher Aristotle rejected it.

Finally, in the 17th century, the English scientist Robert Boyle argued that, by definition, an element is composed of “simple Bodies, not made of any other Bodies, of which all mixed Bodies are compounded, and into which they are ultimately resolved,” a description remarkably close to our idea of an element, with atoms being the “simple Bodies.” The next two centuries saw rapid progress in chemistry and the development of a “billiard-ball” image of the atom. Then, an early 20th-century burst of creativity led to our current model of an atom with a complex internal structure.

IN THIS CHAPTER . . . We examine the properties and composition of matter on the macroscopic and atomic scales.

- › We relate the three types of observable matter—elements, compounds, and mixtures—to the atoms, ions, and molecules they consist of.
- › We classify mixtures and see how to separate them in the lab.
- › We see how the defining properties of the types of matter relate to 18th-century laws concerning the masses of substances that react with each other.
- › We examine the 19th-century atomic model proposed to explain these laws.
- › We describe some 20th- and 21st-century experiments that have led to our current understanding of atomic structure and atomic mass.
- › We focus on the general organization of the elements in the periodic table and introduce the two major ways that elements combine.
- › We derive names and formulas of compounds and calculate their masses on the atomic scale.
- › We examine some of the ways chemists depict molecules.
- › We present a final overview of the components of matter.

2.1 ELEMENTS, COMPOUNDS, AND MIXTURES: AN ATOMIC OVERVIEW

Based on its composition, matter can be broadly classified into two types—substances and mixtures.

A **substance** is matter with a *fixed* composition while a **mixture** consists of two or more substances that are physically combined with a *variable* composition.

Substances

Substances can be further subdivided into elements and compounds:

1. *Elements.* An **element** is the simplest type of matter with unique physical and chemical properties.

The following are some features of elements:

- An element consists of only one kind of **atom**, the smallest unit of an element that retains its chemical nature, and therefore cannot be broken down into a simpler type of matter by any physical or chemical methods.
- Each element is unique because the properties of its atoms are unique. An element has a name, such as silicon, oxygen, or copper. A sample of silicon contains only silicon atoms, and a sample of copper contains only copper atoms. The *macroscopic* properties of a piece of silicon, such as color, density, and combustibility, are different from those of a piece of copper because the *submicroscopic* properties of silicon atoms are different from those of copper atoms.
- In nature, most elements exist as populations of atoms, either separated or in contact with each other, depending on the physical state. Figure 2.1A shows atoms of an element in its gaseous state.
- Several elements occur in molecular form; a **molecule** is an independent structure of two or more atoms bound together (Figure 2.1B). Oxygen, for example, occurs in air as *diatomic* (two-atom) molecules, O_2 .

2. *Compounds.* A **compound** consists of two or more different elements that are bonded chemically (Figure 2.1C). That is, the elements in a compound are not just mixed together: their atoms have joined in a chemical reaction. Many compounds, such as ammonia, water, and carbon dioxide, consist of molecules. But many others, like sodium chloride (which we'll discuss shortly) and silicon dioxide, do not.

All compounds have three defining features:

- *The elements are present in fixed parts by mass* (have a fixed mass ratio). This is so because *each unit of the compound consists of a fixed number of atoms of each element*. For example, consider a sample of ammonia. It is 14 parts nitrogen by mass and 3 parts hydrogen by mass *because* 1 nitrogen atom has 14 times the mass of 1 hydrogen atom, and each ammonia molecule consists of 1 nitrogen atom and 3 hydrogen atoms:

Ammonia gas is 14 parts N by mass and 3 parts H by mass.
1 N atom has 14 times the mass of 1 H atom.

Each ammonia molecule consists of 1 N atom and 3 H atoms.

- *A compound's properties are different from the properties of its elements.* Table 2.1 shows a striking example: soft, silvery sodium metal and yellow-green, poisonous chlorine gas are very different from the compound they form—white, crystalline sodium chloride, or common table salt!
- *A compound, unlike an element, can be broken down into simpler substances—its component elements—by a chemical change.* For example, an electric current breaks down molten sodium chloride into metallic sodium and chlorine gas.

Mixtures

In a mixture, two or more substances (elements and/or compounds) are physically intermingled, *not* chemically combined.

Mixtures differ from compounds as follows:

- *The components of a mixture can vary in their parts by mass.* A mixture of the compounds sodium chloride and water, for example, can have many different parts by mass of salt to water.

A Atoms of an element

B Molecules of an element

C Molecules of a compound

D Mixture of two elements and a compound

Figure 2.1 Elements, compounds, and mixtures on the atomic scale. The samples depicted here are gases, but the types of matter also occur as liquids and solids.

Table 2.1 | Some of the Very Different Properties of Sodium, Chlorine, and Sodium Chloride

Property	Sodium	+	Chlorine	→	Sodium Chloride	
Melting point	97.8°C		−101°C		801°C	
Boiling point	881.4°C		−34°C		1413°C	
Color	Silvery		Yellow-green		Colorless (white)	
Density	0.97 g/cm ³		0.0032 g/cm ³		2.16 g/cm ³	
Behavior in water	Reacts		Dissolves slightly		Dissolves freely	

Source: (Sodium, Chlorine, Sodium chloride) Stephen Frisch/McGraw Hill

- *A mixture retains many of the properties of its components.* Saltwater, for instance, is colorless like water and tastes salty like sodium chloride. The component properties are maintained because, on the atomic scale, a mixture consists of the individual units of its component elements and/or compounds (Figure 2.1D).
- *Mixtures, unlike compounds, can be separated into their components by physical changes; chemical changes are not needed.* For example, the water in saltwater can be boiled off, a physical process that leaves behind solid sodium chloride. Some other separation methods are discussed below.

Classification and Separation of Mixtures

In the natural world, *matter usually occurs as mixtures*. A sample of clean air, for example, consists of many elements and compounds physically mixed together, including oxygen, nitrogen, carbon dioxide, water vapor, and a few other gaseous elements. The oceans are mixtures of numerous substances dissolved in water, and living things contain thousands of substances—carbohydrates, proteins, and nuclei acids, to name a few.

The two broad classes of mixtures—**heterogeneous mixtures** and **homogeneous mixtures (solutions)**—are detailed in Table 2.2.

Table 2.2 | Heterogeneous and Homogeneous Mixtures

Heterogeneous Mixtures	Homogeneous Mixtures (Solutions)
• One or more visible boundaries among the components • The composition is not uniform throughout the mixture, but rather varies from one region of the mixture to another • In some heterogeneous mixtures like milk, the boundaries can only be seen with a microscope • Example: sand (colored blue) mixed with water	• Has no visible boundaries • Has a uniform composition • The components of a homogenous mixture are uniformly intermingled on a molecular level • Cannot visually tell whether a sample of matter is a homogeneous mixture or an element or compound. • Example: blue copper(II) sulfate mixed with water

Source: Holly Curry/McGraw Hill; Matt Meadows/McGraw Hill

Figure 2.2 The distinction between mixtures and compounds. **A**, A mixture of iron and sulfur consists of the two elements. **B**, The compound iron(II) sulfide consists of an array of Fe^{2+} and S^{2-} ions. Source: Stephen Frisch/McGraw Hill

The difference between a mixture and a compound is well illustrated using iron and sulfur as components (Figure 2.2). Any proportions of iron metal filings and powdered sulfur form a mixture. The components can be separated with a magnet because iron metal is magnetic. But if we heat the container strongly, the components will form the compound iron(II) sulfide (FeS). The magnet can then no longer remove the iron because it has undergone a chemical change and lost its magnetic properties.

Chemists have devised many procedures for separating a mixture into its components; the techniques depend on the differences in the *physical properties* of the substances in the mixture; no chemical changes occur:

- **Filtration** is based on *differences in particle size* and is often used to separate a solid from a liquid, which flows through the tiny holes in filter paper as the solid is retained. In vacuum filtration, reduced pressure below the filter speeds the flow of the liquid through it.
- **Crystallization** is based on *differences in solubility*. The *solubility* of a substance is the amount that dissolves in a fixed volume of solvent at a given temperature. Since solubility often increases with temperature, the impure solid is dissolved in hot solvent and, when the mixture cools, the purified compound solidifies (crystallizes).
- **Distillation** separates components through *differences in volatility*, the tendency of a substance to become a gas. *Simple distillation* separates components with *large* differences in volatility, such as water from dissolved ionic compounds. The mixture is boiled, producing a vapor that is richer in the more volatile component—in this case, water. The water boils off and is condensed and collected separately, leaving the solid compound behind. *Fractional distillation* (discussed in Chapter 13) uses many vaporization-condensation steps to separate components with small volatility differences, such as those in petroleum.
- **Chromatography** is also based on *differences in solubility*. The mixture is dissolved in a gas or liquid, and the components are separated as this solution, called the *mobile phase*, flows through a solid (or viscous liquid) called the *stationary phase*. A component with lower solubility in the stationary phase moves through it faster than a component with a higher solubility. In one technique, called *gas-liquid chromatography (GLC)*, the mobile phase is an inert gas, such as helium, that carries a gaseous mixture of components into a long tube packed with the stationary phase (Figure 2.3A). The components emerge separately and reach a detector. A chromatogram has numerous peaks, each representing the amount of a specific component (Figure 2.3B). *High-performance (high-pressure) liquid chromatography (HPLC)* is similar to GLC, but the mixture need not be vaporized, since the mobile phase is a liquid, so more heat-sensitive components can be separated.

Figure 2.3 Principle of gas-liquid chromatography (GLC). The stationary phase is shown as a viscous liquid (gray circles) coating the solid beads (yellow) of an inert packing.

The following sample problem will help you to differentiate elements, compounds, and mixtures.

SAMPLE PROBLEM 2.1

Distinguishing Elements, Compounds, and Mixtures at the Atomic Scale

Problem The scenes below represent atomic-scale views of three samples of matter:

Describe each sample as an element, a compound, or a mixture.

Plan We have to determine the type of matter by examining the component particles. If a sample contains only one type of particle, it is either an element or a compound; if it contains more than one type, it is a mixture. Particles of an element have only one kind of atom (one color of sphere in an atomic-scale view), and particles of a compound have two or more kinds of atoms.

Solution (a) **Mixture:** there are three different types of particles. Two types contain only one kind of atom, either green or purple, so they are elements (composed of diatomic molecules), and the third type contains two red atoms for every one yellow, so it is a compound.

(b) **Element:** the sample consists of only blue atoms.

(c) **Compound:** the sample consists of molecules that each have two black and six blue atoms.

FOLLOW-UP PROBLEMS

Brief Solutions for all Follow-up Problems appear at the end of the chapter.

2.1A Does each of the following scenes best represent an element, a compound, or a mixture?

2.1B Describe the following representation of a reaction in terms of elements, compounds, and mixtures.

SOME SIMILAR PROBLEMS 2.3, 2.4, and 2.14

Figure 2.4 The classification of matter.

Figure 2.4 summarizes the classification of matter that we have discussed in this section.

› Summary of Section 2.1

- › All matter exists as either elements, compounds, or mixtures.
- › Every element or compound is a substance, matter with a fixed composition.
- › An element consists of only one type of atom and occurs as a collection of individual atoms or molecules; a molecule consists of two or more atoms chemically bonded together.
- › A compound contains two or more elements chemically combined and exhibits different properties from its component elements. The elements occur in fixed parts by mass because each unit of the compound has a fixed number of each type of atom. Only a chemical change can break down a compound into its elements.
- › A mixture consists of two or more substances mixed together, *not* chemically combined. The components exhibit their individual properties, can be present in any proportion, and can be separated by physical changes.
- › Heterogeneous mixtures have visible boundaries among the components.
- › Homogeneous mixtures (solutions) have no visible boundaries because mixing occurs at the molecular level.
- › Separation methods are based on differences in physical properties and include filtration (particle size), crystallization (solubility), distillation (volatility), and chromatography (solubility).

2.2 THE OBSERVATIONS THAT LED TO AN ATOMIC VIEW OF MATTER

Any model of the composition of matter had to explain three so-called mass laws: the *law of mass conservation*, the *law of definite (or constant) composition*, and the *law of multiple proportions*.

Mass Conservation

The first mass law, stated by Lavoisier on the basis of combustion experiments, was the most fundamental chemical observation of the 18th century:

- **Law of mass conservation:** *the total mass of substances does not change during a chemical reaction.*

Figure 2.5 The law of mass conservation. Source: Stephen Frisch/McGraw Hill

The *number* of substances may change and, by definition, their properties must, but the *total amount* of matter remains constant. Figure 2.5 illustrates mass conservation because the lead nitrate and sodium chromate solutions (*left*) have the same mass as the solid lead chromate in sodium nitrate solution (*right*) that forms after their reaction.

Even in a complex biochemical change, such as the metabolism of the sugar glucose, which involves many reactions, mass is conserved. For example, in the reaction of, say, 180 g of glucose, with oxygen, we have

Mass conservation means that, based on all chemical experience, *matter cannot be created or destroyed*.

To be precise about it, however, we now know, based on the work of Albert Einstein (1879–1955), that the mass before and after a reaction is not *exactly* the same. Some mass is converted to energy, or vice versa, but the difference is too small to measure, even with the best balance. For example, when 100 g of carbon burns, the carbon dioxide formed weighs 0.000000036 g (3.6×10^{-8} g) less than the sum of the carbon and oxygen that reacted. Because the energy changes of *chemical* reactions are so small, for all practical purposes, mass *is* conserved. Later in the text, you'll see that energy changes in *nuclear* reactions are so large that mass changes are easy to measure.

Definite Composition

We stated earlier that there is a fixed proportion of elements in a particular compound; we can express that fixed proportion in two ways:

- The **fraction by mass (mass fraction)** is the part of the compound's mass that each element contributes. It is obtained by dividing the mass of each element in the compound by the mass of the compound:

$$\text{Mass fraction} = \frac{\text{mass of element X in compound A}}{\text{mass of compound A}}$$

- The **percent by mass (mass percent, mass %)** is the fraction by mass expressed as a percentage (multiplied by 100):

$$\text{Mass percent} = \text{mass fraction} \times 100$$

For an everyday example, consider a box that contains three types of marbles: yellow ones weigh 1.0 g each, purple 2.0 g each, and red 3.0 g each. Each type

Figure 2.6 The law of definite composition. Calcium carbonate occurs in many forms (such as marble, *top*, and coral, *bottom*).

Source: (top): Matthia Cortesi (Roman sculptor active 100–150 CE)/atthiam/123RF; (bottom): Alexander Cherednichenko/Shutterstock

makes up a fraction of the total mass of marbles, 16.0 g. The *mass fraction* of yellow marbles is their number times their mass divided by the total mass:

$$\begin{aligned}\text{Mass fraction of yellow marbles} &= \frac{\text{no. of yellow marbles} \times \text{mass of yellow marbles}}{\text{total mass of marbles}} \\ &= \frac{3 \text{ marbles} \times 1.0 \text{ g / marble}}{16.0 \text{ g}} = 0.19\end{aligned}$$

The *mass percent* (parts per 100 parts) of yellow marbles is $0.19 \times 100 = 19\%$ by mass. Similarly, the purple marbles have a mass fraction of 0.25 and represent 25% by mass of the total, and the red marbles have a mass fraction of 0.56 and represent 56% by mass of the total.

Now let's apply this idea to the compound calcium carbonate, composed of three elements—calcium, carbon, and oxygen. Calcium carbonate is the major compound in seashells, marble, and coral. Let's consider a 20.0 g sample of calcium carbonate from a marble statue (Sample I) and a 45.0 g sample from coral (Sample II):

	Analysis by Mass	Mass Fraction	Mass Percent
Sample I 20.0 g	8.0 g calcium	$\frac{8.0 \text{ g calcium}}{20.0 \text{ g calcium carbonate}} = 0.40$	$0.40 \times 100 = 40\%$
	2.4 g carbon	$\frac{2.4 \text{ g carbon}}{20.0 \text{ g calcium carbonate}} = 0.12$	$0.12 \times 100 = 12\%$
	9.6 g oxygen	$\frac{9.6 \text{ g oxygen}}{20.0 \text{ g calcium carbonate}} = 0.48$	$0.48 \times 100 = 48\%$
Sample II 45.0 g	18.0 g calcium	$\frac{18.0 \text{ g calcium}}{45.0 \text{ g calcium carbonate}} = 0.40$	$0.40 \times 100 = 40\%$
	5.4 g carbon	$\frac{5.4 \text{ g carbon}}{45.0 \text{ g calcium carbonate}} = 0.12$	$0.12 \times 100 = 12\%$
	21.6 g oxygen	$\frac{21.6 \text{ g oxygen}}{45.0 \text{ g calcium carbonate}} = 0.48$	$0.48 \times 100 = 48\%$

We can draw two conclusions from this data:

- The sum of the mass fractions (or mass percents) equals 1.00 part (or 100%) by mass.
- Both samples of this compound contain 40.% calcium, 12% carbon, and 48% oxygen by mass (Figure 2.6).

The second conclusion is expressed as the second mass law:

- **Law of definite (or constant) composition:** *no matter what its source, a particular compound is composed of the same elements in the same parts (fractions) by mass.*

Because a given element always constitutes the same mass fraction of a given compound, we can use that mass fraction to find the actual mass of the element in any sample of the compound:

$$\begin{aligned}\text{Mass of element in sample} \\ = \text{mass of compound in sample} \times \frac{\text{mass of element in compound}}{\text{mass of compound}}\end{aligned}\quad (2.1)$$

For example, knowing that a 20.0-g sample of calcium carbonate contains 8.0 g of calcium, the mass of calcium in a 75.0-g sample of calcium carbonate can be calculated:

$$\begin{aligned}\text{Mass (g) of calcium} &= 75.0 \text{ g calcium carbonate} \times \frac{8.0 \text{ g calcium}}{20.0 \text{ g calcium carbonate}} \\ &= 30.0 \text{ g calcium}\end{aligned}$$

SAMPLE PROBLEM 2.2 | Calculating the Mass of an Element in a Compound

Problem Pitchblende is the most important compound of uranium. Mass analysis of an 84.2-g sample of pitchblende shows that it contains 71.4 g of uranium, with oxygen the only other element. How many grams of uranium and of oxygen are in 102 kg of pitchblende?

Plan We have to find the masses (in g) of uranium and of oxygen in a known mass (102 kg) of pitchblende, given the mass of uranium (71.4 g) in a different mass of pitchblende (84.2 g) and knowing that oxygen is the only other element present. The mass *ratio* of uranium to pitchblende in grams is the same as it is in kilograms. Therefore, using Equation 2.1, we multiply the mass (in kg) of the pitchblende sample by the ratio of uranium to pitchblende (in kg) from the mass analysis. This gives the mass (in kg) of uranium, and we convert kilograms to grams. To find the mass of oxygen, the only other element in the pitchblende, we subtract the calculated mass of uranium (in kg) from the given mass of pitchblende (102 kg) and convert kilograms to grams.

Solution Finding the mass (kg) of uranium in 102 kg of pitchblende:

$$\begin{aligned}\text{Mass (kg) of uranium} &= \text{mass (kg) of pitchblende} \times \frac{\text{mass (kg) of uranium in pitchblende}}{\text{mass (kg) of pitchblende}} \\ &= 102 \text{ kg pitchblende} \times \frac{71.4 \text{ kg uranium}}{84.2 \text{ kg pitchblende}} = 86.5 \text{ kg uranium}\end{aligned}$$

Converting the mass of uranium from kg to g:

$$\text{Mass (g) of uranium} = 86.5 \text{ kg uranium} \times \frac{1000 \text{ g}}{1 \text{ kg}} = 8.65 \times 10^4 \text{ g uranium}$$

Finding the mass (in kg) of oxygen in 102 kg of pitchblende:

$$\begin{aligned}\text{Mass (kg) of oxygen} &= \text{mass (kg) of pitchblende} - \text{mass (kg) of uranium} \\ &= 102 \text{ kg} - 86.5 \text{ kg} = 15.5 \text{ kg oxygen}\end{aligned}$$

Converting the mass of oxygen from kg to g:

$$\text{Mass (g) of oxygen} = 15.5 \text{ kg oxygen} \times \frac{1000 \text{ g}}{1 \text{ kg}} = 1.55 \times 10^4 \text{ g oxygen}$$

Check The analysis showed that most of the mass of pitchblende is due to uranium, so the large mass of uranium makes sense. Rounding off to check the math gives

$$\sim 100 \text{ kg pitchblende} \times \frac{70}{85} = 82 \text{ kg uranium}$$

FOLLOW-UP PROBLEMS

2.2A The mineral “fool’s gold” does not contain any gold; instead, it is a compound composed only of the elements iron and sulfur. A 110.0-g sample of fool’s gold contains 51.2 g of iron. What mass of sulfur is in a sample of fool’s gold that contains 86.2 g of iron?

2.2B Silver bromide is the light-sensitive compound coated onto black-and-white film. A 26.8-g sample contains 15.4 g of silver, with bromine as the only other element. How many grams of each element are on a roll of film that contains 3.57 g of silver bromide?

Road Map

Student Hot Spot

Student data indicate that you may struggle with using mass fraction to calculate the mass of an element in a compound. Access the eBook to view an additional Learning Resource video on this topic.

Multiple Proportions

It’s quite common for the same two elements to form more than one compound—sulfur and fluorine do this, as do phosphorus and chlorine and many other pairs of elements. The third mass law we consider applies in these cases:

- **Law of multiple proportions:** *if elements A and B react to form two compounds, the different masses of B that combine with a fixed mass of A can be expressed as a ratio of small whole numbers.*

Consider two compounds of carbon and oxygen; let's call them carbon oxides I and II. These compounds have very different properties: the density of carbon oxide I is 1.25 g/L, whereas that of II is 1.98 g/L; I is poisonous and flammable, but II is not. Mass analysis shows that

Carbon oxide I is 57.1 mass % oxygen and 42.9 mass % carbon
Carbon oxide II is 72.7 mass % oxygen and 27.3 mass % carbon

To demonstrate the phenomenon of multiple proportions, we use the mass percents of oxygen and of carbon to find their masses in a given mass, say 100 g, of each compound. Then we divide the mass of oxygen by the mass of carbon in each compound to obtain the mass of oxygen that combines with a fixed mass of carbon:

	Carbon Oxide I	Carbon Oxide II
g oxygen/100 g compound	57.1	72.7
g carbon/100 g compound	42.9	27.3
g oxygen/g carbon	$\frac{57.1}{42.9} = 1.33$	$\frac{72.7}{27.3} = 2.66$

If we then divide the grams of oxygen per gram of carbon in II by that in I, we obtain a ratio of small whole numbers:

$$\frac{2.66 \text{ g oxygen/g carbon in II}}{1.33 \text{ g oxygen/g carbon in I}} = \frac{2}{1}$$

The law of multiple proportions tells us that, in two compounds of the same elements, the mass fraction of one element relative to that of the other element changes in *increments based on ratios of small whole numbers*. In this case, the ratio is 2/1—for a given mass of carbon, compound II contains 2 *times* as much oxygen as I, not 1.583 times, 1.716 times, or any other intermediate amount.

The *simplest* arrangement consistent with the mass data for carbon oxides I and II is that one atom of oxygen combines with one atom of carbon in compound I (carbon monoxide) and that two atoms of oxygen combine with one atom of carbon in compound II (carbon dioxide):

Dalton's Atomic Theory

With over 200 years of hindsight, it may be easy to see how the mass laws could be explained by the idea that matter exists in indestructible units, each with a particular mass and set of properties, but it was a major breakthrough in 1808 when John Dalton (1766–1844) presented his atomic theory of matter.

Postulates of the Atomic Theory Dalton expressed his theory in a series of postulates, presented here in modern terms:

1. All matter consists of atoms—tiny, indivisible units of an element that cannot be created or destroyed.
2. Atoms of one element *cannot* be converted into atoms of another element. In chemical reactions, the atoms of the original substances recombine to form different substances.
3. Atoms of an element are identical in mass and other properties and are different from atoms of any other element.
4. Compounds result from the chemical combination of a specific ratio of atoms of different elements.

How the Theory Explains the Mass Laws Let's see how Dalton's postulates explain the mass laws:

- *Mass conservation.* Atoms cannot be created or destroyed (postulate 1) or converted into other types of atoms (postulate 2). Therefore, a chemical reaction cannot possibly result in a mass change because atoms are just combined differently.

- **Definite composition.** A compound is a combination of a *specific* ratio of different atoms (postulate 4), each of which has a particular mass (postulate 3). Thus, each element in a compound must constitute a fixed fraction of the total mass.
- **Multiple proportions.** Atoms of an element have the same mass (postulate 3) and are indivisible (postulate 1). The masses of element B that combine with a fixed mass of element A must give a small, whole-number ratio because different numbers of B atoms combine with each A atom in different compounds, as we saw in the previous example with carbon monoxide and carbon dioxide.

Let's work through a sample problem that reviews the mass laws.

SAMPLE PROBLEM 2.3 | Visualizing the Mass Laws

Problem The scenes below represent an atomic-scale view of a chemical reaction:

Which of the mass laws—mass conservation, definite composition, and/or multiple proportions—is (are) illustrated?

Plan From the depictions, we note the numbers, colors, and combinations of atoms (spheres) to see which mass laws pertain. If the numbers of each atom are the same before and after the reaction, the total mass did not change (mass conservation). If a compound forms that always has the same atom ratio, the elements are present in fixed parts by mass (definite composition). If the same elements form different compounds and the ratio of the atoms of one element that combine with one atom of the other element is a small whole number, the ratio of their masses is a small whole number as well (multiple proportions).

Solution There are seven purple and nine green atoms in each circle, so mass is conserved. The compound formed has one purple and two green atoms, so it has definite composition. Only one compound forms, so the law of multiple proportions does not pertain.

FOLLOW-UP PROBLEMS

2.3A The following scenes represent a chemical change. Which of the mass laws is (are) illustrated?

2.3B Which sample(s) best display(s) the fact that compounds of bromine (orange) and fluorine (yellow) exhibit the law of multiple proportions? Explain.

SOME SIMILAR PROBLEMS 2.22 and 2.23

› Summary of Section 2.2

- › The law of mass conservation states that the total mass remains constant during a chemical reaction.
- › The law of definite composition states that any sample of a given compound has the same elements present in the same parts by mass.
- › The law of multiple proportions states that, in different compounds of the same elements, the masses of one element that combine with a fixed mass of the other can be expressed as a ratio of small whole numbers.
- › Dalton's atomic theory explained the mass laws by proposing that all matter consists of indivisible, unchangeable atoms of fixed, unique mass.
- › Mass is conserved during a reaction because the atoms retain their identities but are combined differently.
- › Each compound has a fixed mass fraction of each of its elements because it is composed of a fixed number of each type of atom.
- › Different compounds of the same elements exhibit multiple proportions because they each consist of whole atoms.

2.3 THE OBSERVATIONS THAT LED TO THE NUCLEAR ATOM MODEL

One of the postulates of Dalton's atomic theory was that atoms were indivisible and thus it did not predict the existence of subatomic charged particles, which were observed in experiments at the turn of the 20th century that led to the discovery of *electrons* and the atomic *nucleus*. Let's examine some of the experiments that resolved questions about Dalton's model and led to our current model of atomic structure.

Discovery of the Electron and Its Properties

For many years, scientists knew that matter and electric charge are related. When amber is rubbed with fur, or glass with silk, positive and negative charges form—the same charges that make your hair crackle and cling to your comb on a dry day (*see photo*). Scientists also knew that an electric current can decompose certain compounds into their elements. But they did not know what a current is made of.

Cathode Rays To discover the nature of an electric current, some investigators tried passing it through nearly evacuated glass tubes fitted with metal electrodes. When the electric power source was turned on, a “ray” could be seen striking the phosphor-coated end of the tube, which emitted a glowing spot of light. The rays were called **cathode rays** because they originated at the negative electrode (cathode) and moved to the positive electrode (anode).

Figure 2.7 shows some properties of cathode rays based on these observations. The main conclusion was that *cathode rays consist of negatively charged particles found in all matter*. The rays become visible as their particles collide with the few remaining gas molecules in the evacuated tube. Cathode ray particles were later named *electrons*. There are many familiar cases of the effects of charged particles colliding with gas particles or hitting a phosphor-coated screen:

- In a “neon” sign, electrons collide with the gas particles in the tube, causing them to give off light.
- The aurora borealis, or northern lights (*see photo*), occurs when Earth's magnetic field bends streams of charged particles coming from the Sun, which then collide with gas particles in the atmosphere to give off light.

Effect of electric charges.

Source: Bob Coyle/McGraw Hill

Aurora borealis display.

Source: Roman Krochuk/Shutterstock

Figure 2.7 Observations that established the properties of cathode rays.

- In older televisions and computer monitors, the cathode ray passes back and forth over the phosphor-coated screen, creating a pattern that we see as a picture.

Mass and Charge of the Electron Two classic experiments and their conclusion revealed the mass and charge of the electron:

1. *Charge/mass ratio.* In 1897, the British physicist J. J. Thomson (1856–1940) used a cathode ray tube to measure the ratio of the electron's electrical charge to its mass and obtained a value of -1.76×10^8 coulombs/g (the coulomb, C, is the SI unit of electrical charge). This value indicated that the electron was about 2000 times lighter than hydrogen, the lightest atom! Thomson was shocked because this implied that, contrary to Dalton's atomic theory, *atoms contain even smaller particles*. Fellow scientists reacted with disbelief to Thomson's conclusion; some even thought he was joking.

2. *Charge.* In 1909, the American physicist Robert Millikan (1868–1953) measured the *charge* of the electron. He did so by observing the movement of tiny oil droplets in an apparatus that contained electrically charged plates and an x-ray source (Figure 2.8). X-rays knocked electrons from gas molecules in the air within the apparatus, and the

Figure 2.8 Millikan's oil-drop experiment for measuring an electron's charge. The total charge on an oil droplet is some whole-number multiple of the charge of the electron.

electrons stuck to an oil droplet falling through a hole in a positively charged plate. With the electric field off, Millikan measured the mass of the now negatively charged droplet from its rate of fall. Then, by adjusting the field's strength, he made the droplet slow and hang suspended, which allowed him to measure its total charge.

After many tries, Millikan found that the total charge of the various droplets was always some *whole-number multiple of a minimum charge*. If different oil droplets picked up different numbers of electrons, Millikan reasoned that this minimum charge must be the charge of the electron itself. Remarkably, the value that he calculated over a century ago was within 1% of the modern value of the electron's charge, -1.602×10^{-19} C.

3. *Conclusion: calculating the electron's mass.* The value of the electron's charge multiplied by its mass/charge ratio gives the electron's mass, which is *extremely small*:

$$\text{Mass of electron} = \cancel{\text{charge}} \times \frac{\text{mass}}{\cancel{\text{charge}}} = -1.602 \times 10^{-19} \text{ C} \times \frac{\text{g}}{-1.76 \times 10^8 \text{ C}} = 9.10 \times 10^{-28} \text{ g}$$

Discovery of the Atomic Nucleus

The presence of electrons in all matter brought up two major questions about the structure of atoms. Matter is electrically neutral, so atoms must be also. But if atoms contain negatively charged electrons, what positive charges balance them? And if an electron has such a tiny mass, what accounts for an atom's much larger mass? To address these issues, Thomson proposed his “plum-pudding” model—a spherical atom composed of diffuse, positively charged matter with electrons embedded in it like “raisins in a plum pudding.”

In 1910, New Zealand-born physicist Ernest Rutherford (1871–1937) tested this model and obtained a very unexpected result (Figure 2.9):

1. *Experimental design.* Figure 2.9A shows the experimental setup, in which tiny, dense, positively charged alpha (α) particles emitted from radium are aimed at gold foil. A circular, zinc-sulfide screen registers the deflection (scattering angle) of the α particles emerging from the foil by emitting light flashes when the particles strike it.

Figure 2.9 Rutherford's α -scattering experiment and discovery of the atomic nucleus.

2. *Hypothesis and expected results.* With Thomson's model in mind (Figure 2.9B), Rutherford expected only minor, if any, deflections of the α particles because they should act as bullets and go right through the gold atoms. After all, he reasoned, an electron should not be able to deflect an α particle any more than a Ping-Pong ball could deflect a baseball.
3. *Actual results.* Initial results were consistent with this hypothesis, but then the unexpected happened (Figure 2.9C). As Rutherford recalled: "I remember two or three days later Geiger [one of his coworkers] coming to me in great excitement and saying, 'We have been able to get some of the α particles coming backwards . . . ' It was quite the most incredible event that has ever happened to me in my life. It was almost as incredible as if you fired a 15-inch shell at a piece of tissue paper and it came back and hit you." The data showed very few α particles deflected at all and only 1 in 20,000 deflected by more than 90° ("coming backwards").
4. *Rutherford's conclusion.* Rutherford concluded that these few α particles were being repelled by something small, dense, and positive within the gold atoms. Calculations based on the mass, charge, and velocity of the α particles and the fraction of these large-angle deflections showed that
 - An atom is mostly space occupied by electrons.
 - In the center is a tiny region, which Rutherford called the **nucleus**, that contains all the positive charge and essentially all the mass of the atom.

He proposed that positive particles lay within the nucleus and called them *protons*.

Rutherford's model explained the charged nature of matter, but it could not account for all the atom's mass. After more than 20 years, in 1932, James Chadwick (1891–1974) discovered the *neutron*, an uncharged, dense particle that also resides in the nucleus.

› Summary of Section 2.3

- › Several major discoveries at the turn of the 20th century resolved questions about Dalton's model and led to our current model of atomic structure.
- › Cathode rays were shown to consist of negative particles (electrons) that exist in all matter. J. J. Thomson measured their charge/mass ratio and concluded that they are much smaller and lighter than atoms.
- › Robert Millikan determined the charge of the electron, which he combined with other data to calculate its mass.
- › Ernest Rutherford proposed that atoms consist of a tiny, massive, positively charged nucleus surrounded by electrons.

2.4 THE ATOMIC THEORY TODAY

Dalton's model of an indivisible particle has given way to our current model of an atom with an elaborate internal architecture of subatomic particles.

Structure of the Atom

An *atom* is an electrically neutral, spherical entity composed of a positively charged central nucleus surrounded by one or more negatively charged electrons (Figure 2.10).

Let's examine some of its features:

- The electrons move rapidly within the available volume, held there by the attraction of the nucleus. (To indicate their motion, they are often depicted as a cloudy blur of color, darkest around a central dot—the nucleus—and becoming paler toward the outer edge.)
- The nucleus consists of protons and neutrons (the only exception is the simplest nucleus of the element hydrogen, which is just a proton).
- The **proton** (p^+) has a positive charge and the **neutron** (n^0) has no charge; all of the positive charge of the nucleus results from its protons.
- The charge of the proton is the same magnitude as the charge of an **electron** (e^-) but with the opposite sign. *An atom is neutral because the number of protons in the nucleus equals the number of electrons surrounding the nucleus.*

The Tiny, Massive Nucleus

A few analogies can help you grasp the incredible properties of the atomic nucleus. A nucleus the size of the period at the end of a sentence would weigh about 100 tons, as much as 50 cars! An atom the size of the Houston Astrodome would have a nucleus the size of a green pea that would contain virtually all the stadium's mass. If the nucleus were about 1 cm in diameter, the atom would be about 200 m across, or more than the length of two football fields!

Figure 2.10 General features of the atom.

- The mass of a proton or neutron is nearly 2000 times larger than the mass of the electron.
- An atom's diameter ($\sim 1 \times 10^{-10}$ m) is about 20,000 times the diameter of its nucleus ($\sim 5 \times 10^{-15}$ m).
- The nucleus contributes 99.97% of the atom's mass but occupies only about 1 quadrillionth of its volume, so it is incredibly dense: about 10^{14} g/mL! ➤

Some properties of these three subatomic particles are listed in Table 2.3.

Atomic Number, Mass Number, and Atomic Symbol

We use a standard atom notation to describe an atom of an element; this atom notation has three parts (Figure 2.11A):

1. Atomic number:
 - The **atomic number** (Z) of an element equals the number of protons in the nucleus of each of its atoms.
 - The Z value is written as a left subscript in the notation.
 - Since the number of protons must equal the number of electrons in an atom, the atomic number also equals the number of electrons in the atom.
 - All atoms of an element have the same atomic number, and the atomic number of each element is different from that of any other element. All carbon atoms ($Z = 6$) have 6 protons, all oxygen atoms ($Z = 8$) have 8 protons, and all uranium atoms ($Z = 92$) have 92 protons.
2. Mass number:
 - The **mass number** (A) is the total number of protons and neutrons in the nucleus of an atom.
 - The A value is written as a left superscript in the notation.
 - Each proton and each neutron contributes one unit to the mass number. Thus, a carbon atom with 6 protons and 6 neutrons in its nucleus has a mass number of 12, and a uranium atom with 92 protons and 146 neutrons in its nucleus has a mass number of 238.

Table 2.3 | Properties of the Three Key Subatomic Particles

Name (Symbol)	Charge		Mass		Location in Atom
	Relative	Absolute (C)*	Relative (amu) [†]	Absolute (g)	
Proton (p^+)	1+	$+1.60218 \times 10^{-19}$	1.00727	1.67262×10^{-24}	Nucleus
Neutron (n^0)	0	0	1.00866	1.67493×10^{-24}	Nucleus
Electron (e^-)	1−	-1.60218×10^{-19}	0.00054858	9.10939×10^{-28}	Outside nucleus

*The coulomb (C) is the SI unit of charge.
[†]The atomic mass unit (amu) equals 1.66054×10^{-24} g; it is discussed later in this section.

3. Atomic symbol:

- The **atomic symbol** (or *element symbol*), designated as X in Figure 2.11A, is a one- or two-letter abbreviation for the English, Latin, or Greek name of an element.
- Examples are C for carbon, Cl for chlorine, and Na for sodium (Latin *natrium*).

The number of neutrons (N) is not formally part of the atom notation. But since the mass number is the sum of protons and neutrons, the number of neutrons in an atom can be calculated by subtracting the atomic number from the mass number:

$$\text{Number of neutrons} = \text{mass number} - \text{atomic number, or } N = A - Z \quad (2.2)$$

Thus, a chlorine atom, symbolized ${}^{35}_{17}\text{Cl}$, has $A = 35$, $Z = 17$, and $N = 35 - 17 = 18$. Because each element has its own atomic number, we also know the atomic number from the symbol. For example, instead of writing ${}^{12}_6\text{C}$ for carbon with mass number 12, we can write ${}^{12}\text{C}$ (spoken “carbon twelve”), with $Z = 6$ understood. Another way to name this atom is carbon-12.

Isotopes

All atoms of an element have the same atomic number but not the same mass number.

Isotopes of an element are atoms that have *different numbers of neutrons* and therefore different mass numbers. Most elements occur in nature in a particular *isotopic composition*, which specifies the proportional abundance of each of its isotopes. For example, all carbon atoms ($Z = 6$) have 6 protons and 6 electrons, but only 98.89% of naturally occurring carbon atoms have 6 neutrons ($A = 12$). A small percentage (1.11%) have 7 neutrons ($A = 13$), and even fewer (less than 0.01%) have 8 ($A = 14$). These are carbon’s three naturally occurring isotopes— ${}^{12}\text{C}$, ${}^{13}\text{C}$, and ${}^{14}\text{C}$. A natural sample of carbon has these three isotopes in these relative proportions. Five other carbon isotopes— ${}^9\text{C}$, ${}^{10}\text{C}$, ${}^{11}\text{C}$, ${}^{15}\text{C}$, and ${}^{16}\text{C}$ —have been created in the laboratory. Figure 2.11B depicts the atomic number, mass number, and symbol for four atoms, two of which are isotopes of the element uranium.

A key point is that the chemical properties of an element are primarily determined by the number of electrons, so *all isotopes of an element have nearly identical chemical behavior*, even though they have different masses.

SAMPLE PROBLEM 2.4

Determining the Numbers of Subatomic Particles in the Isotopes of an Element

Problem Silicon (Si) is a major component of semiconductor chips. It has three naturally occurring isotopes: ${}^{28}\text{Si}$, ${}^{29}\text{Si}$, and ${}^{30}\text{Si}$. Determine the numbers of protons, electrons, and neutrons in an atom of each silicon isotope.

Plan The mass number (A ; left superscript) of each of the three isotopes is given, which is the sum of protons and neutrons. From the List of Elements in the front of the book, we find the atomic number (Z , number of protons), which equals the number of electrons. We obtain the number of neutrons by subtracting Z from A (Equation 2.2).

Solution From the List of Elements, the atomic number of silicon is 14. Therefore,

${}^{28}\text{Si}$ has 14p^+ , 14e^- , and 14n^0 ($28 - 14$)

${}^{29}\text{Si}$ has 14p^+ , 14e^- , and 15n^0 ($29 - 14$)

${}^{30}\text{Si}$ has 14p^+ , 14e^- , and 16n^0 ($30 - 14$)

FOLLOW-UP PROBLEMS

2.4A Titanium, the ninth most abundant element, is used structurally in many objects, such as electric turbines, aircraft bodies, and bicycle frames. It has five naturally occurring isotopes: ${}^{46}\text{Ti}$, ${}^{47}\text{Ti}$, ${}^{48}\text{Ti}$, ${}^{49}\text{Ti}$, and ${}^{50}\text{Ti}$. How many protons, electrons, and neutrons are in an atom of each isotope?

2.4B An atom has a mass number of 88 and has 50 neutrons. (a) What is the element? (b) Another isotope of this element has a mass number of 86. How many neutrons does this isotope have?

SOME SIMILAR PROBLEMS 2.46–2.49

Atomic Masses of the Elements

The mass of an atom is measured *relative* to the mass of an atomic standard. The modern standard is the carbon-12 atom, whose mass is defined as *exactly* 12 atomic mass units. Thus, the **atomic mass unit (amu)** is $\frac{1}{12}$ the mass of a carbon-12 atom. Based on this standard, the ^1H atom has a mass of 1.008 amu; in other words, a ^{12}C atom has almost 12 times the mass of an ^1H atom. We will continue to use the term *atomic mass unit* in the text, although the name of the unit has been changed to the **dalton (Da)**; thus, one ^{12}C atom has a mass of 12 daltons (12 Da, or 12 amu). The atomic mass unit is a relative unit of mass, but it is equivalent to an absolute mass of 1.66054×10^{-24} g.

Finding Atomic Mass from Isotopic Composition The isotopic composition of an element is determined by **mass spectrometry**, a method for measuring the relative masses and abundances of atomic-scale particles very precisely.

In this powerful technique, high-energy electrons collide with a particle—say, an atom of neon-20—knocking away one of the atom’s electrons to produce a particle that has one positive charge, Ne^+ (Figure 2.12A). Thus, the particle has a mass/charge ratio (m/e) that equals its mass divided by 1^+ . Figure 2.12B depicts the process for a sample of neon’s three naturally occurring isotopes. The positively charged particles are attracted toward a series of negatively charged plates with slits in them. Some particles pass through the slits into an evacuated tube exposed to a magnetic field. As the particles enter this region, their paths are bent; the lightest particles (lowest m/e) are deflected most and the heaviest particles (highest m/e) least. At the end of the region, the particles strike a detector, which records their relative positions and abundances (Figure 2.12C). The relative abundance is the percentage (or fraction) of each isotope in a sample of the element. For example, the relative abundance of ^{20}Ne is 90.48% (or 0.9048), which

Figure 2.12 The mass spectrometer and its data.
A, Formation of a positively charged neon particle (Ne^+).
B, Particles are separated by their m/e values. **C**, The percent abundance of each isotope.

means that 90.48% of the neon atoms in a naturally occurring sample of neon have a mass number of 20. The remainder of a neon sample is 0.27% ^{21}Ne and 9.25% ^{22}Ne .

The mass spectrometer also provides the mass ratio of an isotope, such as ^{20}Ne , to ^{12}C :

$$\frac{\text{Mass of } ^{20}\text{Ne atom}}{\text{Mass of } ^{12}\text{C standard}} = 1.666037$$

From this mass ratio, we find the **isotopic mass** of the ^{20}Ne atom, the mass of this neon isotope relative to that of ^{12}C :

$$\begin{aligned}\text{Isotopic mass of } ^{20}\text{Ne} &= \text{measured mass ratio} \times \text{mass of } ^{12}\text{C} \\ &= 1.666037 \times 12 \text{ amu} = 19.99244 \text{ amu}\end{aligned}$$

From the isotopic mass and relative abundance data, we can obtain the **atomic mass** (also called *atomic weight*) of an element, the *average* of the masses of its naturally occurring isotopes *weighted according to their abundances*. Each naturally occurring isotope of an element contributes a certain portion to the atomic mass; that portion is calculated by multiplying the mass of each naturally occurring isotope by its fractional abundance. The individual portions are summed to find the average atomic mass of the element:

$$\text{Atomic mass} = \Sigma(\text{isotopic mass})(\text{fractional abundance of isotope}) \quad (2.3)$$

where the fractional abundance of an isotope is the percent natural abundance of the isotope divided by 100 and the symbol Σ indicates a sum. For instance, we use the data from the mass spectrometric analysis of neon (Figure 2.12C) to calculate the average atomic mass of neon:

Isotope	Isotopic Mass (amu)	% Relative Abundance	Fractional Abundance	Isotopic Mass $\times$ Fractional Abundance
^{20}Ne	19.99244	90.48	0.9048	$19.99244 \text{ amu} \times 0.9048 = 18.0892 \text{ amu}$
^{21}Ne	20.99385	0.27	0.0027	$20.99385 \text{ amu} \times 0.0027 = 0.05668 \text{ amu}$
^{22}Ne	21.99139	9.25	0.0925	$21.99139 \text{ amu} \times 0.0925 = 2.0342 \text{ amu}$
				Average atomic mass = Sum = 20.18008 amu = 20.18 amu

The atomic mass is an average value; that is, while no individual neon atom has a mass of 20.18 amu, in the laboratory, we consider a sample of neon to consist of atoms with this average mass. Notice that, since the ^{20}Ne isotope is much more abundant (90.48%) than the other two isotopes, the atomic mass of neon is much closer to the mass of that isotope than to the masses of the two heavier isotopes.

SAMPLE PROBLEM 2.5 | Calculating the Atomic Mass of an Element

Problem Silver (Ag; $Z = 47$) has 46 known isotopes, but only 2 occur naturally, ^{107}Ag and ^{109}Ag . Given the following data, calculate the atomic mass of Ag:

Isotope	Mass (amu)	Abundance (%)
^{107}Ag	106.90509	51.84
^{109}Ag	108.90476	48.16

Plan From the mass and abundance of the two Ag isotopes, we have to find the atomic mass of Ag (weighted average of the isotopic masses). We divide each percent abundance by 100 to get the fractional abundance and then multiply that by each isotopic mass to find the portion of the atomic mass contributed by each isotope. The sum of the isotopic portions is the atomic mass (Equation 2.3).

Road Map

Solution Finding the fractional abundances:

$$\text{Fractional abundance of } ^{107}\text{Ag} = 51.84/100 = 0.5184; \text{ similarly, } ^{109}\text{Ag} = 0.4816$$

Finding the portion of the atomic mass from each isotope:

$$\begin{aligned} \text{Portion of atomic mass from } ^{107}\text{Ag} &= \text{isotopic mass} \times \text{fractional abundance} \\ &= 106.90509 \text{ amu} \times 0.5184 = 55.42 \text{ amu} \end{aligned}$$

$$\text{Portion of atomic mass from } ^{109}\text{Ag} = 108.90476 \text{ amu} \times 0.4816 = 52.45 \text{ amu}$$

Finding the atomic mass of silver:

$$\text{Atomic mass of Ag} = 55.42 \text{ amu} + 52.45 \text{ amu} = 107.87 \text{ amu}$$

Or, in one step using Equation 2.3:

$$\begin{aligned} \text{Atomic mass of Ag} &= (\text{isotopic mass of } ^{107}\text{Ag})(\text{fractional abundance of } ^{107}\text{Ag}) \\ &\quad + (\text{isotopic mass of } ^{109}\text{Ag})(\text{fractional abundance of } ^{109}\text{Ag}) \\ &= (106.90509 \text{ amu})(0.5184) + (108.90476 \text{ amu})(0.4816) \\ &= 107.87 \text{ amu} \end{aligned}$$

Check The individual portions seem right: $\sim 100 \text{ amu} \times 0.50 = 50 \text{ amu}$. The portions should be almost the same because the two isotopic abundances are almost the same. We rounded each portion to four significant figures because that is the number of significant figures in the abundance values.

FOLLOW-UP PROBLEMS

2.5A Silicon, an important semiconductor, has three naturally occurring isotopes: ^{28}Si , ^{29}Si , and ^{30}Si . Use the following information to determine the atomic mass of silicon: ^{28}Si has a mass of 27.97693 amu and an abundance of 92.23%, ^{29}Si has a mass of 28.976495 amu and an abundance of 4.67%, and ^{30}Si has a mass of 29.973770 amu and an abundance of 3.10%.

2.5B Boron (B; $Z = 5$) has two naturally occurring isotopes. Find the percent abundances of ^{10}B and ^{11}B given these data: atomic mass of B = 10.81 amu, isotopic mass of ^{10}B = 10.0129 amu, and isotopic mass of ^{11}B = 11.0093 amu. (*Hint:* The sum of the fractional abundances is 1. If x = abundance of ^{10}B , then $1 - x$ = abundance of ^{11}B .)

SOME SIMILAR PROBLEMS 2.54–2.57

The Atomic-Mass Interval From the time Dalton proposed his atomic theory through much of the 20th century, atomic masses were considered constants of nature, like the speed of light. However, in 1969, the International Union of Pure and Applied Chemistry (IUPAC) rejected this idea because results from more advanced mass spectrometers showed consistent variations in isotopic composition from source to source.

In 2009, IUPAC proposed that an *atomic-mass interval* be used for 10 elements with exceptionally large variations in isotopic composition: hydrogen (H), lithium (Li), boron (B), carbon (C), nitrogen (N), oxygen (O), silicon (Si), sulfur (S), chlorine (Cl), and thallium (Th). More recently, magnesium (Mg), bromine (Br), and argon (Ar) have each been assigned an atomic-mass interval as well. For example, because the isotopic composition of hydrogen from oceans, rivers, and lakes, from various minerals, and from organic sediments varies so much, its atomic mass is now given as the interval [1.00784; 1.00811], which means that the mass is greater than or equal to 1.00784 and less than or equal to 1.00811. It's important to realize that *the mass of any given isotope of an element is constant, but the proportion of isotopes varies from source to source.*

The atomic-mass interval is important for very precise work; however, because this text uses only four or five significant figures for atomic masses in calculations—for

example, 1.008 amu for the atomic mass of H—the change does not affect our discussions (see the List of Elements in the front of the book). Also, such small differences in composition do not overturn the basic idea of the law of definite composition: elements occur in a fixed proportion by mass in a compound, no matter what the source (Section 2.2).

› Summary of Section 2.4

- › An atom has a central nucleus, which contains positively charged protons and uncharged neutrons and is surrounded by negatively charged electrons. An atom is neutral because the number of electrons equals the number of protons.
- › An atom is represented by the notation ${}_Z^AX$, in which Z is the atomic number (number of protons), A the mass number (sum of protons and neutrons), and X the atomic symbol.
- › An element occurs naturally as a mixture of isotopes, atoms with the same number of protons but different numbers of neutrons. Each isotope has a mass relative to the ^{12}C mass standard.
- › The atomic mass of an element is the average of its isotopic masses weighted according to their natural abundances. It is determined using a mass spectrometer.

2.5 ELEMENTS: A FIRST LOOK AT THE PERIODIC TABLE

At the end of the 18th century, 23 elements were known; by 1870, 65 were known; by 1925, 88; today, there are 118 (90 occur in nature and 28 have been synthesized by nuclear scientists)! By the mid-19th century, enormous amounts of information concerning reactions, properties, and atomic masses of the elements had been accumulated. Several researchers noted recurring, or *periodic*, patterns of behavior and proposed schemes to organize the elements according to some fundamental property.

In 1871, the Russian chemist Dmitri Mendeleev (1836–1907) published the most successful of these organizing schemes as a table of the elements listed by increasing atomic mass and arranged so that elements with similar chemical properties fell in the same column. The modern **periodic table of the elements**, based on Mendeleev's version (but arranged by *atomic number*, not mass), is one of the great classifying schemes in science and an indispensable tool to chemists—and chemistry students.

Organization of the Periodic Table One common version of the modern periodic table appears in the front of the book and in Figure 2.13. It is formatted as follows:

- Each element has a box that contains its atomic number, atomic symbol, and atomic mass. (A mass in parentheses is the mass number of the most stable isotope of that element.)
- The boxes lie, from left to right, in order of *increasing atomic number*, Z (number of protons in the nucleus).
- The boxes are arranged into a grid of **periods** (horizontal rows) and **groups** (vertical columns).
- Each period has a number from 1 to 7; each group has a number from 1 to 18.*
- Groups 1, 2 and 13–18 contain the *main-group elements*.
- Groups 3–12 contain the *transition elements*.
- Two horizontal series of *inner transition elements*, the lanthanides and actinides, fit between the elements in Groups 3 and 4 and are placed below the main body of the table.

*In some versions of the periodic table, Groups 1, 2, and 13–18 are labeled Groups 1A–8A, while Groups 3–12 are given "B" designations.

Period

- The **metals** (*three shades of blue* in Figure 2.13) lie in the large, lower-left portion of the table. About three-quarters of the elements are metals, including many main-group elements and all the transition and inner transition elements. They are generally shiny solids at room temperature (mercury is the only liquid) that conduct heat and electricity well. They can be tooled into sheets (are malleable) and wires (are ductile).
- The **nonmetals** (*yellow*) lie in the small, upper-right portion of the table (with the exception of the nonmetal hydrogen in the upper-left corner). They are generally gases or dull, brittle solids at room temperature (bromine is the only liquid) and conduct heat and electricity poorly.
- The **metalloids** (*green*; also called **semimetals**), which lie along the staircase line, have properties between those of metals and nonmetals.

Following are two major points to keep in mind:

1. In general, elements in a group have *similar* chemical properties, and elements in a period have *different* chemical properties.

Figure 2.14 Some metals, metalloids, and nonmetals. Source: Stephen Frisch/McGraw Hill

2. Despite the classification of elements into three types, in reality there is a gradation in properties from left to right and top to bottom.

It is important to learn some of the group (family) names:

- Group 1 (except for hydrogen)—*alkali metals* (reactive metals)
- Group 2—*alkaline earth metals* (reactive metals)
- Group 17—*halogens* (reactive nonmetals)
- Group 18—*noble gases* (relatively nonreactive nonmetals)

Other main groups, 13 to 16, are often named for the first element in the group; for example, Group 16 is the *oxygen family*.

SAMPLE PROBLEM 2.6 | Identifying an Element from Its Z Value

Problem From each of the following Z values, give the name, symbol, and group and period numbers of the element, and classify it as a main-group metal, transition metal, inner transition metal, nonmetal, or metalloid: (a) $Z = 38$; (b) $Z = 17$; (c) $Z = 27$.

Plan The Z value is the atomic number of an element. The List of Elements in the front of the book is alphabetical, so we look up the name and symbol of the element. Then we use the periodic table to find the group number (top of the column) and the period number (left end of the row) in which the element is located. We classify the element from the color coding in the periodic table.

Solution

(a) Strontium, Sr, is in Group 2 and Period 5, and it is a main-group metal.

(b) Chlorine, Cl, is in Group 17 and Period 3, and it is a nonmetal.

(c) Cobalt, Co, is in Group 9 and Period 4, and it is a transition metal.

Check You can work backwards by starting at the top of the group and moving down to the period to check that you get the correct Z value.

Comment Strontium is one of the alkaline earth metals, and chlorine is a halogen.

FOLLOW-UP PROBLEMS

2.6A Identify each of the following elements from its Z value; give the name, symbol, and group and period numbers, and classify it as a main-group metal, transition metal, inner transition metal, nonmetal, or metalloid: (a) $Z = 14$; (b) $Z = 55$; (c) $Z = 54$.

2.6B Identify each of the following elements from its Z value; give the name, symbol, and group and period numbers, and classify it as a main-group metal, transition metal, inner transition metal, nonmetal, or metalloid: (a) $Z = 12$; (b) $Z = 7$; (c) $Z = 30$.

SOME SIMILAR PROBLEMS 2.63 and 2.64

Summary of Section 2.5

- › In the periodic table, the elements are arranged by atomic number into horizontal periods and vertical groups.
- › Nonmetals appear in the upper-right portion of the table, metalloids lie along a staircase line, and metals fill the rest of the table.
- › Elements within a group have similar behavior, whereas elements within a period have dissimilar behavior.

2.6 COMPOUNDS: INTRODUCTION TO BONDING

Aside from a few exceptions, *the overwhelming majority of elements occur in nature in compounds combined with other elements.*

Only a few elements occur free in nature:

- The noble gases—helium (He), neon (Ne), argon (Ar), krypton (Kr), xenon (Xe), and radon (Rn)—occur in air as separate atoms.
- Oxygen (O), nitrogen (N), and sulfur (S) occur in their most common elemental form as the molecules O_2 , N_2 , and S_8 .
- Carbon (C) occurs in vast, nearly pure deposits of coal.
- Some metals—copper (Cu), silver (Ag), gold (Au), and platinum (Pt)—are sometimes found uncombined.

Elements combine in two general ways, and both involve *the electrons of the atoms of interacting elements*:

1. *Transferring electrons* from atoms of one element to atoms of another to form **ionic compounds**
2. *Sharing electrons* between atoms of different elements to form **covalent compounds**

These processes generate **chemical bonds**, the forces that hold the atoms together in a compound. This section introduces compound formation, which we'll discuss in much more detail in later chapters.

The Formation of Ionic Compounds

Ionic compounds are composed of **ions**, charged particles that form when an atom (or small group of atoms) gains or loses one or more electrons. The simplest type of ionic compound is a **binary ionic compound**, one composed of ions of two elements. It typically forms *when a metal reacts with a nonmetal*:

- Each metal atom *loses* one or more electrons and becomes a **cation**, a positively charged ion.
- Each nonmetal atom *gains* one or more of the electrons lost by the metal atom and becomes an **anion**, a negatively charged ion.

In effect, the metal atoms *transfer electrons* to the nonmetal atoms. The resulting large numbers of oppositely charged cations and anions attract each other by *electrostatic*

Figure 2.15 The formation of an ionic compound. **A**, The two elements as seen in the laboratory. **B**, The elements on the atomic scale. **C**, The electron transfer from Na atom to Cl atom to form Na^+ and Cl^- ions, shown schematically. **D**, Countless Na^+ and Cl^- ions attract each other and form a regular three-dimensional array. **E**, Crystalline NaCl occurs naturally as the mineral halite. Source: A(1–2), E: Stephen Frisch/McGraw Hill

forces and form the ionic compound. A cation or an anion derived from a single atom is called a **monatomic ion**; we'll discuss *polyatomic ions*, those derived from a small group of atoms, later.

The Case of Sodium Chloride All binary ionic compounds are solid arrays of oppositely charged ions. The formation of the binary ionic compound sodium chloride, common table salt, from its elements, solid sodium metal and chlorine gas, is depicted in Figure 2.15:

- A sodium atom loses one electron and forms a sodium cation, Na^+ . (The charge on the ion is written as a *right superscript*. For a charge of $1+$ or $1-$, the 1 is not written; for charges of larger magnitude, the sign is written *after* the number: $2+$.)
- A chlorine atom *gains* the electron lost by the sodium atom and becomes a chloride anion, Cl^- . (The name change—chlorine to *chloride*—when the nonmetal atom becomes an anion is discussed in Section 2.7.)
- The oppositely charged ions (Na^+ and Cl^-) attract each other, and the similarly charged ions (Na^+ and Na^+ , or Cl^- and Cl^-) repel each other.
- The resulting solid aggregation is a regular array of alternating Na^+ and Cl^- ions that extends in all three dimensions. Even the tiniest visible grain of table salt contains an enormous number of sodium and chloride ions.

Predicting the Number of Electrons Lost or Gained Ionic compounds are neutral because they contain equal numbers of positive and negative charges. Thus, there are equal numbers of Na^+ and Cl^- ions in sodium chloride because both ions are singly charged. But there are two Na^+ ions for each oxide ion, O^{2-} , in sodium oxide because it takes two $1+$ ions to balance one $2-$ ion.

Can we predict the number of electrons a given atom will lose or gain when it forms an ion? For main-group elements, we usually find that metal atoms lose electrons and nonmetal atoms gain electrons to form ions with the same number of electrons as in an atom of the nearest noble gas (Group 18). Noble gases have a stability that is related to their number (and arrangement) of electrons. Thus, a sodium atom ($11e^-$) can attain the stability of a neon atom ($10e^-$), the nearest noble gas, by losing one electron. Similarly, a chlorine atom ($17e^-$) attains the stability of an argon atom ($18e^-$), its nearest noble gas, by gaining one electron. Thus, in general, when an element located near a noble gas forms a monatomic ion,

- *Metals lose electrons:* elements in Group 1 lose one electron, elements in Group 2 lose two, and aluminum in Group 3 loses three.
- *Nonmetals gain electrons:* elements in Group 17 gain one electron, oxygen and sulfur in Group 16 gain two, and nitrogen in Group 15 gains three.

In the periodic table in Figure 2.13, it looks like the elements in Group 17 are “closer” to the noble gases than the elements in Group 1. In truth, both groups are only one electron away from having the number of electrons in the nearest noble gas. Figure 2.16 shows a periodic table of monatomic ions that has the left and right sides joined so that it forms a cylinder. Note that fluorine (F; $Z = 9$) has one electron *fewer* than the noble gas neon (Ne; $Z = 10$) and sodium (Na; $Z = 11$) has one electron *more*; thus, they form the F^- and Na^+ ions. Similarly, oxygen (O; $Z = 8$) gains two electrons and magnesium (Mg; $Z = 12$) loses two to form the O^{2-} and Mg^{2+} ions and attain the same number of electrons as neon. In Figure 2.16, species in a row have the same number of electrons.

Species in a row (e.g., S^{2-} , Cl^- , Ar, K^+ , Ca^{2+}) have the same number of electrons.

15	16	17	18	1	2	13
		H^-	He	Li^+		
N^{3-}	O^{2-}	F^-	Ne	Na^+	Mg^{2+}	Al^{3+}
	S^{2-}	Cl^-	Ar	K^+	Ca^{2+}	
		Br^-	Kr	Rb^+	Sr^{2+}	
		I^-	Xe	Cs^+	Ba^{2+}	

Figure 2.16 The relationship between the ion an element forms and the nearest noble gas.

Atoms far apart: No interactions.

Atoms closer: Attractions (green arrows) between nucleus of one atom and electron of the other increase. Repulsions between nuclei and between electrons are very weak.

Optimum distance: H_2 molecule forms because attractions (green arrows) balance repulsions (red arrows).

SAMPLE PROBLEM 2.7 Predicting the Ion an Element Forms

Problem What monatomic ions would you expect the following elements to form?

(a) Iodine ($Z = 53$) (b) Calcium ($Z = 20$) (c) Aluminum ($Z = 13$)

Plan We use the given Z value to find the element in the periodic table and see where its group lies relative to the noble gases. Elements in Groups 1, 2, and 13 *lose* electrons to attain the same number as the nearest noble gas and become positive ions; those in Groups 15, 16, and 17 *gain* electrons and become negative ions.

Solution (a) I^- Iodine ($_{53}I$) is in Group 17, the halogens. Like any member of this group, it gains one electron to attain the same number as the nearest Group 18 member—in this case, $_{54}Xe$.

(b) Ca^{2+} Calcium ($_{20}Ca$) is in Group 2, the alkaline earth metals. Like any Group 2 member, it loses two electrons to attain the same number as the nearest noble gas, $_{18}Ar$.

(c) Al^{3+} Aluminum ($_{13}Al$) is a metal in the boron family (Group 13) and thus loses three electrons to attain the same number as its nearest noble gas, $_{10}Ne$.

FOLLOW-UP PROBLEMS

2.7A What monatomic ion would you expect each of the following elements to form:

(a) $_{16}S$; (b) $_{37}Rb$; (c) $_{56}Ba$?

2.7B Identify each of the following elements from its description:

(a) The third period element that forms the monoatomic ion, X^{2+}

(b) The fourth period element that forms the monoatomic ion X^-

(c) The second period element that forms the monoatomic ion X^{2-}

SOME SIMILAR PROBLEMS 2.76 and 2.77

The Formation of Covalent Substances

Covalent substances form when atoms of elements share electrons, which usually occurs between nonmetals.

Covalent Bonding in Elements and Some Simple Compounds The simplest case of electron sharing occurs not in a compound but in elemental hydrogen, between two hydrogen atoms (H ; $Z = 1$); the formation of the covalent bond is shown in Figure 2.17:

- Two separated H atoms approach each other; as they get closer, the nucleus of each atom attracts the electron of the other atom more and more strongly.
- As the separated atoms begin to interpenetrate each other, repulsions between the nuclei and between the electrons begin to increase.
- At some optimum distance between the nuclei, the two atoms form a **covalent bond**, a pair of electrons mutually attracted by the two nuclei.
- The result is a hydrogen molecule, in which each electron no longer “belongs” to a particular H atom: the two electrons are *shared* by the two nuclei.
- A sample of hydrogen gas consists of these diatomic molecules (H_2)—pairs of atoms that are chemically bound, each pair behaving as a unit—not separate H atoms.

Figure 2.18 shows other nonmetal elements that exist as covalently bonded molecules at room temperature.

Atoms of **different** elements share electrons to form the molecules of a covalent compound. A sample of hydrogen fluoride, for example, consists of molecules in which one H atom forms a covalent bond with one F atom; water consists of molecules in which one O atom forms covalent bonds with two H atoms (see margin).

Distinguishing the Entities in Covalent and Ionic Substances There are two key distinctions between the chemical entities in covalent substances and those in ionic substances.

	1	2		13	14	15	16	17	18
1	H ₂								
2						N ₂	O ₂	F ₂	
3						P ₄	S ₈	Cl ₂	
4							Se ₈	Br ₂	
5								I ₂	
6									
7									

■ Diatomic molecules
■ Tetratomic molecules
■ Octatomic molecules

Figure 2.18 Elements that occur as molecules.

1. *Most covalent substances consist of molecules.* A cup of water, for example, consists of individual water molecules lying near each other. In contrast, under ordinary conditions, *there are no molecules in an ionic compound.* A piece of sodium chloride, for example, is a continuous array in three dimensions of oppositely charged sodium and chloride ions, *not* a collection of individual sodium chloride “molecules.”
2. *The nature of the particles attracting each other in covalent and in ionic substances is fundamentally different.* Covalent bonding involves the mutual attraction between two (positively charged) nuclei and the two (negatively charged) electrons that reside between them. Ionic bonding involves the mutual attraction between positive and negative ions.

Polyatomic Ions: Covalent Bonds Within Ions Many ionic compounds contain **polyatomic ions**, which consist of two or more atoms bonded *covalently* and have a net positive or negative charge. For example, Figure 2.19 shows that a crystalline form of calcium carbonate (*left*) occurs on the atomic scale (*center*) as an array of polyatomic carbonate anions and monatomic calcium cations. The carbonate ion (*right*) consists of a carbon atom *covalently* bonded to three oxygen atoms, and two additional electrons give the ion its 2− charge. In many reactions, the polyatomic ion stays together as a unit.

Figure 2.19 The carbonate ion in calcium carbonate.

› Summary of Section 2.6

- › Although a few elements occur uncombined in nature, the great majority exist in compounds.
- › Ionic compounds form when a metal *transfers* electrons to a nonmetal, and the resulting positive and negative ions attract each other to form a three-dimensional array. In many cases, metal atoms lose and nonmetal atoms gain enough electrons to attain the same number of electrons as in atoms of the nearest noble gas.
- › Covalent compounds form when elements, usually nonmetals, *share* electrons. Each covalent bond is an electron pair mutually attracted by two atomic nuclei.
- › Monatomic ions are derived from single atoms. Polyatomic ions consist of two or more covalently bonded atoms that have a net positive or negative charge due to a deficit or an excess of electrons.

Table 2.4 Common Monatomic Ions*

Charge	Formula	Name
Cations		
1+	H ⁺	hydrogen
	Li ⁺	lithium
	Na ⁺	sodium
	K ⁺	potassium
	Rb ⁺	rubidium
	Cs ⁺	cesium
2+	Ag ⁺	silver
	Mg ²⁺	magnesium
	Ca ²⁺	calcium
	Sr ²⁺	strontium
	Ba ²⁺	barium
	Zn ²⁺	zinc
3+	Cd ²⁺	cadmium
	Al ³⁺	aluminum
Anions		
1−	H [−]	hydride
	F [−]	fluoride
	Cl [−]	chloride
	Br [−]	bromide
2−	I [−]	iodide
	O ^{2−}	oxide
2−	S ^{2−}	sulfide
3−	N ^{3−}	nitride

*Listed by charge; those in **boldface** are most common.

2.7 COMPOUNDS: FORMULAS, NAMES, AND MASSES

In a **chemical formula**, element symbols and, often, numerical subscripts show the type and number of each atom in the smallest unit of the substance. In this section, you'll learn how to write the names and formulas of ionic and simple covalent compounds, how to calculate the mass of a compound from its formula, and how to visualize molecules with three-dimensional models. To make learning the names and formulas of compounds easier, we'll rely on various rules, so be prepared for a bit of memorization and a lot of practice.

Ionic Compounds

We'll start with ionic compounds. Recall that ionic compounds are generally composed of a metal cation and a nonmetal anion. The names and formulas of all ionic compounds give the cation (the positive ion) first and the anion (the negative ion) second. Let's look at the naming rules for four types of ionic compounds.

Binary Ionic Compounds of Elements That Form One Ion Most main-group elements and a few transition metals form an ion with only one charge as listed in Table 2.4. Notice the following to help you remember these monoatomic ion charges:

- Group 1 elements form ions with a 1+ charge
- Group 2 elements form ions with a 2+ charge.
- The element Al in Group 13 forms ions with a 3+ charge.
- The transition metal Ag forms ions with a 1+ charge; Zn and Cd form ions with a 2+ charge.
- Main-group nonmetal elements form anions whose charge equals the group number minus 18; for example, S is in Group 16 (16 − 18 = −2) and thus forms S^{2−}.

Figure 2.20 illustrates the naming rules for binary ionic compounds of elements that form ions with only one charge:

- The cation is named first and the anion second.
- The name of the cation is the name of the metal.
- The anion name has the suffix *-ide* added to the root of the nonmetal name.

We can use the charges of the ions in an ionic compound to write the formula of the compound. The compound has zero net charge, so the positive charges of the cations balance the negative charges of the anions. For example, calcium bromide is composed of Ca²⁺ ions and Br[−] ions, so two Br[−] balance each Ca²⁺ and the formula is CaBr₂. In this and all other formulas,

- The subscript refers to the element symbol *preceding* it.
- The *subscript "1" is understood* from the presence of the element symbol alone (that is, we do not write Ca₁Br₂).
- The charge (without the sign) of one ion becomes the subscript of the other:

- The subscripts are reduced to the smallest whole numbers that retain the ratio of ions. Thus, for example, for the Ca²⁺ and O^{2−} ions in calcium oxide, we get Ca₂O₂, which we reduce to the formula CaO.*

The following sample problem applies these rules.

Figure 2.20 Naming binary ionic compounds in which the metal forms a single ion.

*Compounds of the mercury(I) ion, such as Hg₂Cl₂, and peroxides of the alkali metals, such as Na₂O₂, are the only two common exceptions to this step: reducing the subscripts for these compounds would give the incorrect formulas HgCl and NaO.

SAMPLE PROBLEM 2.8

Determining Names and Formulas of Binary Ionic Compounds of Elements That Form One Ion

Problem Give the name and formula of the ionic compound formed from the following pairs of elements:

- (a) Magnesium and nitrogen
- (b) Iodine and cadmium
- (c) Strontium and fluorine
- (d) Sulfur and cesium

Plan The key to naming a binary ionic compound is to recognize which element is the metal and which is the nonmetal. When in doubt, check the periodic table. We place the cation name first, add the suffix *-ide* to the nonmetal root, and place the anion name second. Use the periodic table or Table 2.4 to find the charge of each monatomic ion. We write the formula by finding the smallest number of each ion that gives the neutral compound. These numbers appear as *right subscripts* to the element symbol.

Solution (a) Magnesium is the metal; *nitr-* is the nonmetal root: **magnesium nitride**.

Mg^{2+} and N^{3-} ; three Mg^{2+} ions (6+) balance two N^{3-} ions (6-): **Mg_3N_2** .

(b) Cadmium is the metal; *iod-* is the nonmetal root: **cadmium iodide**.

Cd^{2+} and I^- ; one Cd^{2+} ion (2+) balances two I^- ions (2-): **CdI_2** .

(c) Strontium is the metal; *fluor-* is the nonmetal root: **strontium fluoride**. (Note the spelling is *fluoride*, not *flouride*.)

Sr^{2+} and F^- ; one Sr^{2+} ion (2+) balances two F^- ions (2-): **SrF_2** .

(d) Cesium is the metal; *sulf-* is the nonmetal root: **cesium sulfide**.

Cs^+ and S^{2-} ; two Cs^+ ions (2+) balance one S^{2-} ion (2-): **Cs_2S** .

Comment 1. The subscript “1” is understood and so not written; thus, in (b), we do *not* write Cd_1I_2 .

2. Ion charges do *not* appear in the compound formula; for example, in (c), we do *not* write $\text{Sr}^{2+}\text{F}_2^-$.

FOLLOW-UP PROBLEMS

2.8A Give the name and formula of the ionic compound formed from the following pairs of elements:

- (a) Zinc and oxygen
- (b) Bromine and silver
- (c) Lithium and chlorine
- (d) Sulfur and aluminum

2.8B Give the name and formula of the ionic compound formed from the following pairs of elements:

- (a) Potassium and sulfur
- (b) Iodine and barium
- (c) Nitrogen and cesium
- (d) Sodium and hydrogen

SOME SIMILAR PROBLEMS 2.88–2.91

Binary Ionic Compounds of Metals That Form More Than One Ion Many metals, particularly the transition elements, can form more than one ion; Table 2.5 lists some of these elements. For example, copper can form Cu^+ and Cu^{2+} ions and so can form two different compounds with oxygen: Cu_2O and CuO . We cannot give the same name, copper oxide, to the two different compounds, so we need a way to distinguish between them. Ionic compounds with metals that form more than one ion are named like those of elements that form only one monoatomic ion, but with one additional rule (Figure 2.21):

- The cation is named first and the anion second.
- The name of the cation is the name of the metal.
- A roman numeral within parentheses immediately follows the metal ion’s name to indicate its ionic charge.
- The anion name has the suffix *-ide* added to the root of the nonmetal name.

Figure 2.21 Naming binary ionic compounds in which the metal can form more than one ion.

Table 2.5 | Some Metals That Form More Than One Monatomic Ion*

Element	Ion Formula	Systematic Name	Common (Trivial) Name
Chromium	Cr^{2+}	chromium(II)	chromous
	Cr^{3+}	chromium(III)	chromic
Cobalt	Co^{2+}	cobalt(II)	
	Co^{3+}	cobalt(III)	
Copper	Cu^{+}	copper(I)	cuprous
	Cu^{2+}	copper(II)	cupric
Iron	Fe^{2+}	iron(II)	ferrous
	Fe^{3+}	iron(III)	ferric
Lead	Pb^{2+}	lead(II)	
	Pb^{4+}	lead(IV)	
Mercury	Hg_2^{2+}	mercury(I)	mercurous
	Hg^{2+}	mercury(II)	mercuric
Tin	Sn^{2+}	tin(II)	stannous
	Sn^{4+}	tin(IV)	stannic

*Listed alphabetically by metal name; the ions in **boldface** are most common.

Note that the roman numeral indicates the charge, not the subscript, of the ion.

We are focusing here on systematic names, but some common (trivial) names are still used. In common names for certain metal ions, the Latin root of the metal is followed by either of two suffixes (see Table 2.5):

- The suffix *-ous* for the ion with the lower charge
- The suffix *-ic* for the ion with the higher charge

Thus, copper(I) oxide is also called cuprous oxide and copper(II) oxide is cupric oxide. (Memory aid: there is an *o* in *-ous* and *lower*, and an *i* in *-ic* and *higher*.)

SAMPLE PROBLEM 2.9**Determining Names and Formulas of Ionic Compounds of Metals That Form More Than One Ion**

Problem Give the systematic name for the formula or the formula for the name:

- (a) Tin(II) fluoride (b) CrI_3 (c) Ferric oxide (d) CoS

Solution (a) Tin(II) ion is Sn^{2+} ; fluoride is F^- . Two F^- ions balance one Sn^{2+} ion: tin(II) fluoride is SnF_2 . (The common name is stannous fluoride.)

(b) The anion is I^- , iodide, and the formula shows three I^- . Therefore, the cation must be Cr^{3+} , chromium(III) ion: CrI_3 is chromium(III) iodide. (The common name is chromic iodide.)

(c) *Ferric* is the common name for the iron(III) ion, Fe^{3+} ; oxide ion is O^{2-} . To balance the charges, the formula is Fe_2O_3 . [The systematic name is iron(III) oxide.]

(d) The anion is sulfide, S^{2-} , which requires that the cation be Co^{2+} . The name is cobalt(II) sulfide.

FOLLOW-UP PROBLEMS

2.9A Give the systematic name for the formula or the formula for the name:

- (a) lead(IV) oxide (a component of car batteries); (b) Cu_2S ; (c) FeBr_2 ; (d) mercuric chloride

2.9B Give the systematic name for the formula or the formula for the name:

- (a) copper(II) nitride; (b) PbI_2 ; (c) chromic sulfide; (d) FeO

SOME SIMILAR PROBLEMS 2.92 and 2.93

Ionic Compounds That Contain Polyatomic Ions Many ionic compounds contain polyatomic ions, some of the more common of which are listed in Table 2.6. Remember that *the polyatomic ion stays together as a charged unit*. Ionic compounds containing polyatomic ions are named like binary ionic compounds with the exception of the name of the anion (Figure 2.22):

- The cation is named first and the anion second.
- The name of the cation is the name of the metal (unless the cation is a polyatomic ion—then use the polyatomic name).
- A roman numeral within parentheses immediately follows the metal ion's name to indicate its ionic charge if the metal can form more than one ion.
- The name of the anion is the name of the polyatomic ion; the suffix *-ide* is not added unless the name of the polyatomic ion, such as hydroxide, already contains that suffix.

When two or more of the same polyatomic ion are present in the formula unit, that ion appears in parentheses with the subscript written outside. For example, calcium nitrate contains one Ca^{2+} and two NO_3^- ions and has the formula $\text{Ca}(\text{NO}_3)_2$. Parentheses and a subscript are *only* used if *more than one* of a given polyatomic ion is present; thus, sodium nitrate is NaNO_3 , *not* $\text{Na}(\text{NO}_3)$.

Families of Oxoanions As Table 2.6 shows, most polyatomic ions are **oxoanions** (or *oxyanions*), those in which an element, usually a nonmetal, is bonded to one or more oxygen atoms. There are several families of two or four oxoanions that differ only in the number of oxygen atoms. The following naming conventions are used with these ions.

With two oxoanions in the family:

- The ion with *more* O atoms takes the nonmetal root and the suffix *-ate*.
- The ion with *fewer* O atoms takes the nonmetal root and the suffix *-ite*.

For example, SO_4^{2-} is the sulf ate ion, and SO_3^{2-} is the sulf ite ion; similarly, NO_3^- is nitr ate , and NO_2^- is nitr ite .

With four oxoanions in the family (a halogen bonded to O) (Figure 2.23):

- The ion with the *most* O atoms has the prefix *per-*, the nonmetal root, and the suffix *-ate*.
- The ion with *one fewer* O atom has just the root and the suffix *-ate*.
- The ion with *two fewer* O atoms has just the root and the suffix *-ite*.
- The ion with the *least (three fewer)* O atoms has the prefix *hypo-*, the root, and the suffix *-ite*.

For example, for the four chlorine oxoanions,

ClO_4^- is *perchlorate*, ClO_3^- is *chlorate*, ClO_2^- is *chlorite*, ClO^- is *hypochlorite*

Hydrated Ionic Compounds Ionic compounds called **hydrates** have a specific number of water molecules in each formula unit. The water molecules are shown after a centered dot in the formula and named with a Greek numerical prefix before the word *hydrate* (Table 2.7). To give just two examples,

Epsom salt: $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ magnesium sulfate *heptahydrate*
(seven water molecules in each formula unit)

Washing soda: $\text{Na}_2\text{CO}_3 \cdot 10\text{H}_2\text{O}$ sodium carbonate *decahydrate*
(ten water molecules in each formula unit)

The water molecules, referred to as “waters of hydration,” are part of the hydrate's structure. Heating can remove some or all of them, leading to a different substance. For example, when heated strongly, blue copper(II) sulfate *pentahydrate* ($\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$) is converted to white copper(II) sulfate (CuSO_4).

Table 2.6	Common Polyatomic Ions*
Formula	Name
Cations	
NH_4^+	ammonium
H_3O^+	hydronium
Anions	
$\text{C}_2\text{H}_3\text{O}_2^-$ (or CH_3COO^-)	acetate
CN^-	cyanide
OH^-	hydroxide
ClO^-	hypochlorite [†]
ClO_2^-	chlorite [†]
ClO_3^-	chlorate [†]
ClO_4^-	perchlorate [†]
NO_2^-	nitrite
NO_3^-	nitrate
MnO_4^-	permanganate
CO_3^{2-}	carbonate
HCO_3^-	hydrogen carbonate (or bicarbonate)
CrO_4^{2-}	chromate
$\text{Cr}_2\text{O}_7^{2-}$	dichromate
O_2^{2-}	peroxide
PO_4^{3-}	phosphate
HPO_4^{2-}	hydrogen phosphate
H_2PO_4^-	dihydrogen phosphate
SO_3^{2-}	sulfite
SO_4^{2-}	sulfate
HSO_4^-	hydrogen sulfate (or bisulfate)

***Boldface** ions are the most common.

[†]Replace Cl with any halogen (Group 17) atom for more ions. Example: BrO^- = hypobromite.

Figure 2.22 Naming ionic compounds containing polyatomic ions.

	Prefix	Root	Suffix
No. of O atoms ↑	per	root	ate
		root	ate
		root	ite
	hypo	root	ite

Figure 2.23 Naming oxoanions. Prefixes and suffixes indicate the number of O atoms in the anion.

Copper(II) sulfate pentahydrate

Copper(II) sulfate

Source: Charles D. Winters/McGraw Hill

Table 2.7 Numerical Prefixes for Hydrates and Binary Covalent Compounds*

Number	Prefix
1	mono-
2	di-
3	tri-
4	tetra-
5	penta-
6	hexa-
7	hepta-
8	octa-
9	nona-
10	deca-

*It is common practice to drop the final *a* from the prefix when naming binary covalent oxides (see the Comment in Sample Problem 2.13).

Student Hot Spot

Student data indicate that you may struggle with writing formulas of ionic compounds containing polyatomic ions. Access the eBook to view an additional Learning Resource video on this topic.

SAMPLE PROBLEM 2.10

Determining Names and Formulas of Ionic Compounds Containing Polyatomic Ions (Including Hydrates)

Problem Give the systematic name for the formula or the formula for the name:

- (a) $\text{Fe}(\text{ClO}_4)_2$ (b) Sodium sulfite (c) $\text{Ba}(\text{OH})_2 \cdot 8\text{H}_2\text{O}$

Solution (a) ClO_4^- is perchlorate, which has a 1− charge, so the cation must be Fe^{2+} . The name is **iron(II) perchlorate**. (The common name is ferrous perchlorate.)

(b) Sodium is Na^+ ; sulfite is SO_3^{2-} , and two Na^+ ions balance one SO_3^{2-} ion. The formula is Na_2SO_3 .

(c) Ba^{2+} is barium; OH^- is hydroxide. There are eight (*octa-*) water molecules in each formula unit. The name is **barium hydroxide octahydrate**.

FOLLOW-UP PROBLEMS

2.10A Give the systematic name for the formula or the formula for the name:

- (a) cupric nitrate trihydrate; (b) zinc hydroxide; (c) LiCN .

2.10B Give the systematic name for the formula or the formula for the name:

- (a) ammonium sulfate; (b) $\text{Ni}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$; (c) potassium bicarbonate.

SOME SIMILAR PROBLEMS 2.94 and 2.95

SAMPLE PROBLEM 2.11

Recognizing Incorrect Names and Formulas of Ionic Compounds

Problem Explain what is wrong with the name or formula at the end of each statement, and correct it:

- (a) $\text{Ba}(\text{C}_2\text{H}_3\text{O}_2)_2$ is called barium diacetate.
 (b) Sodium sulfide has the formula $(\text{Na})_2\text{SO}_3$.
 (c) Iron(II) sulfate has the formula $\text{Fe}_2(\text{SO}_4)_3$.
 (d) Cesium carbonate has the formula $\text{Cs}_2(\text{CO}_3)$.

Solution (a) The charge of the Ba^{2+} ion *must* be balanced by *two* $\text{C}_2\text{H}_3\text{O}_2^-$ ions, so the prefix *di-* is unnecessary. For ionic compounds, we do not indicate the number of ions with numerical prefixes. The correct name is **barium acetate**.

(b) Two mistakes occur here. The sodium ion is monatomic, so it does *not* require parentheses. The sulfide ion is S^{2-} , *not* SO_3^{2-} (which is sulfite). The correct formula is Na_2S .

(c) The roman numeral refers to the charge of the ion, *not* the number of ions in the formula. Fe^{2+} is the cation, so it requires one SO_4^{2-} to balance its charge. The correct formula is FeSO_4 . [$\text{Fe}_2(\text{SO}_4)_3$ is the formula for iron(III) sulfate.]

(d) Parentheses are *not* required when only one polyatomic ion of a particular kind is present. The correct formula is Cs_2CO_3 .

FOLLOW-UP PROBLEMS

2.11A State why the formula or name at the end of each statement is incorrect, and correct it:

- (a) Ammonium phosphate is $(\text{NH}_3)_4\text{PO}_4$.
 (b) Aluminum hydroxide is AlOH_3 .
 (c) $\text{Mg}(\text{HCO}_3)_2$ is manganese(II) carbonate.

2.11B State why the formula or name at the end of each statement is incorrect, and correct it:

- (a) $\text{Cr}(\text{NO}_3)_3$ is chromic(III) nitride.
 (b) $\text{Ca}(\text{NO}_2)_2$ is cadmium nitrate.
 (c) Potassium chlorate is $\text{P}(\text{ClO}_4)$.

SOME SIMILAR PROBLEMS 2.96 and 2.97

Acid Names from Anion Names

Acids are an important group of hydrogen-containing compounds that have been used in chemical reactions for centuries. When naming them and writing their formulas, we consider acids as anions that have one or more hydrogen ions (H^+) added to them to give a neutral compound. The two common types of acids are binary acids and oxoacids:

1. *Binary acid* solutions form when certain gaseous compounds dissolve in water. For example, when gaseous hydrogen chloride (HCl) dissolves in water, it forms hydrochloric acid, which is named as follows:

Prefix *hydro-* + nonmetal *root* + suffix *-ic* + separate word *acid*
 hydro + chlor + ic + acid

or *hydrochloric acid*. This naming pattern holds for many compounds in which hydrogen combines with an anion that has an *-ide* suffix.

2. *Oxoacid* names are similar to those of the oxoanions, except for two suffix changes:

- *-ate* in the anion becomes *-ic* in the acid
- *-ite* in the anion becomes *-ous* in the acid

thus following this pattern:

Oxoanion *root* + suffix *-ic* or *-ous* + separate word *acid*

IO_3^- is iodate, and HIO_3 is iodic acid.

NO_3^- is nitrate, and HNO_3 is nitric acid.

The oxoanion prefixes *hypo-* and *per-* are retained:

BrO_4^- is perbromate, and HBrO_4 is perbromic acid.

Note that the prefix *hydro-* is *not* used when naming oxoacids.

SAMPLE PROBLEM 2.12 | Determining Names and Formulas of Anions and Acids

Problem Name each of the following anions, and give the name and formula of the acid derived from it: (a) Br^- ; (b) IO_3^- ; (c) CN^- ; (d) HSO_4^- .

Solution (a) The anion is bromide; the acid is hydrobromic acid, HBr .

(b) The anion is iodate; the acid is iodic acid, HIO_3 .

(c) The anion is cyanide; the acid is hydrocyanic acid, HCN .

(d) The anion is hydrogen sulfate; the acid is sulfuric acid, H_2SO_4 . (In this case, the suffix is added to the element name *sulfur*, not to the root, *sulf-*.)

FOLLOW-UP PROBLEMS

2.12A Write the formula and name for the anion of each acid: (a) chloric acid; (b) hydrofluoric acid; (c) acetic acid; (d) nitrous acid.

2.12B Name each of the following acids, and give the name and formula of its anion:

- (a) H_2SO_3 (two anions); (b) HBrO ; (c) HClO_2 ; (d) HI .

SOME SIMILAR PROBLEMS 2.98 and 2.99

Binary Covalent Compounds

Binary covalent compounds are typically formed by the combination of two nonmetals. Some are so familiar that we use their common names, such as ammonia (NH_3), methane (CH_4), and water (H_2O), but most are named systematically (Figure 2.24):

- The element with the lower group number in the periodic table comes first in the name. The element with the higher group number comes second and is named with its root and the suffix *-ide*. For example, nitrogen (Group 15) and fluorine (Group 17) form a compound that has three fluorine atoms for every nitrogen atom. The name and formula are nitrogen trifluoride, NF_3 . (*Exception:* When the compound contains oxygen and any of the halogens chlorine, bromine, or iodine, the halogen is named first.)
- If both elements are in the same group, the one with the higher period number is named first. Thus, one compound that the Group 16 elements sulfur (Period 3) and oxygen (Period 2) form is sulfur dioxide, SO_2 .
- Covalent compounds use Greek numerical prefixes (see Table 2.7) to indicate the number of atoms of each element. The first element in the name has a prefix *only* when more than one atom of it is present; the second element *usually* has a prefix.

Figure 2.24 Naming binary covalent compounds.

SAMPLE PROBLEM 2.13

Determining Names and Formulas of Binary Covalent Compounds

Problem (a) What is the formula of carbon disulfide?

(b) What is the name of PCl_5 ?

(c) Give the name and formula of the compound whose molecules each consist of two N atoms and four O atoms.

Solution (a) The prefix *di-* means “two.” The formula is CS_2 .

(b) P is the symbol for phosphorus; there are five chlorine atoms, which is indicated by the prefix *penta-*. The name is **phosphorus pentachloride**.

(c) Nitrogen (N) comes first in the name (lower group number). The compound is **dinitrogen tetroxide**, N_2O_4 .

Comment Note that, as the first elements in the name, carbon in (a) and phosphorus in (b) do not have the prefix *mono-*. In (c), the *a* at the end of the Greek prefix is dropped when the prefix is added to *-oxide*. Similarly, “hexa-oxide” becomes *hexoxide*, “deca-oxide” becomes *decoxide*, and so forth.

FOLLOW-UP PROBLEMS

2.13A Give the name or formula for (a) SO_3 ; (b) SiO_2 ; (c) dinitrogen monoxide; (d) selenium hexafluoride.

2.13B Give the name or formula for (a) SCl_2 ; (b) N_2O_5 ; (c) boron trifluoride; (d) iodine tribromide.

SOME SIMILAR PROBLEMS 2.102 and 2.103

SAMPLE PROBLEM 2.14

Recognizing Incorrect Names and Formulas of Binary Covalent Compounds

Problem Explain what is wrong with the name or formula at the end of each statement, and correct it:

(a) SF_4 is monosulfur pentafluoride.

(b) Dichlorine heptoxide is Cl_2O_6 .

(c) N_2O_3 is dinitrotrioxide.

Solution (a) There are two mistakes. *Mono-* is not needed if there is only one atom of the first element, and the prefix for four is *tetra-*, not *penta-*. The correct name is **sulfur tetrafluoride**.

- (b) The prefix *hepta-* indicates seven, not six. The correct formula is Cl_2O_7 .
 (c) The full name of the first element is needed, and a space separates the two element names. The correct name is dinitrogen trioxide.

FOLLOW-UP PROBLEMS

2.14A Explain what is wrong with the name or formula at the end of each statement, and correct it:

- (a) S_2Cl_2 is disulfurous dichloride.
 (b) Nitrogen monoxide is N_2O .
 (c) BrCl_3 is trichlorine bromide.

2.14B Explain what is wrong with the name or formula at the end of each statement, and correct it:

- (a) P_4O_6 is tetraphosphorous hexaoxide.
 (b) SF_6 is hexafluorosulfide.
 (c) Nitrogen tribromide is NiBr_3 .

SOME SIMILAR PROBLEMS 2.104 and 2.105

Figure 2.25 will help you think through the naming process for most of the types of compounds we have discussed so far. The best way to learn the rules is to practice!

The Simplest Organic Compounds: Straight-Chain Alkanes

Organic compounds typically have complex structures that consist of chains, branches, and/or rings of carbon atoms that are also bonded to hydrogen atoms and, often, to atoms of oxygen, nitrogen, and a few other elements. At this point, we'll name just the simplest organic compounds. Rules for naming other organic compounds are provided in Chapter 15.

Hydrocarbons, the simplest type of organic compound, contain *only* carbon and hydrogen. *Alkanes* are the simplest type of hydrocarbon; many function as important fuels, such as methane, propane, butane, and the mixture that makes up gasoline. The

Figure 2.25 Naming rules for ionic and covalent compounds.

Table 2.8

The First 10
Straight-Chain
Alkanes

Name (Formula)	Model
Methane (CH ₄)	
Ethane (C ₂ H ₆)	
Propane (C ₃ H ₈)	
Butane (C ₄ H ₁₀)	
Pentane (C ₅ H ₁₂)	
Hexane (C ₆ H ₁₄)	
Heptane (C ₇ H ₁₆)	
Octane (C ₈ H ₁₈)	
Nonane (C ₉ H ₂₀)	
Decane (C ₁₀ H ₂₂)	

Figure 2.26 Formula unit for sodium chloride, NaCl. While the compound consists of an array of many Na⁺ and Cl⁻ ions, the formula unit of NaCl consists of just one Na⁺ ion and one Cl⁻ ion.

simplest alkanes to name are the *straight-chain alkanes* because the carbon chains have no branches. Alkanes are named with a *root*, based on the number of C atoms in the chain, followed by the suffix *-ane*.

Table 2.8 gives names, molecular formulas, and space-filling models (discussed shortly) for the first 10 straight-chain alkanes. Note that the roots of the four smallest alkanes are new, but those for the larger ones are the same as the Greek prefixes shown in Table 2.7 (with the final *-a* dropped).

Molecular Masses from Chemical Formulas

In Section 2.6, we saw that most covalent substances consist of molecules, but that there are no molecules in an ionic compound; instead, an ionic compound is composed of oppositely charged ions arranged in a continuous, three-dimensional array. Because an ionic compound consists of an array of ions rather than separate molecules, its formula represents a **formula unit**, which contains the relative numbers of cations and anions in the compound (Figure 2.26).

Using the periodic table and the formula of a compound, we can calculate the **molecular mass** (also called the molecular weight) of a molecule of a covalent compound or the **formula mass** of a formula unit of ionic compound as the sum of the atomic masses:

$$\text{Molecular mass or formula mass} = \text{sum of atomic masses} \quad (2.4)$$

The molecular mass of a water molecule is

$$\begin{aligned} \text{Molecular mass of H}_2\text{O} &= (2 \times \text{atomic mass of H}) + (1 \times \text{atomic mass of O}) \\ &= (2 \times 1.008 \text{ amu}) + 16.00 \text{ amu} = 18.02 \text{ amu} \end{aligned}$$

The formula mass of the formula unit of calcium chloride is

$$\begin{aligned} \text{Formula mass of CaCl}_2 &= (1 \times \text{atomic mass of Ca}) + (2 \times \text{atomic mass of Cl}) \\ &= 40.08 \text{ amu} + (2 \times 35.45 \text{ amu}) = 110.98 \text{ amu} \end{aligned}$$

We can use atomic masses, not ionic masses, because electron loss equals electron gain, so electron mass is balanced.

To calculate the formula mass of a compound with a polyatomic ion, *the number of atoms of each element inside the parentheses is multiplied by the subscript outside the parentheses*. For barium nitrate, Ba(NO₃)₂,

$$\begin{aligned} \text{Formula mass of Ba(NO}_3)_2 &= (1 \times \text{atomic mass of Ba}) + (2 \times \text{atomic mass of N}) + (6 \times \text{atomic mass of O}) \\ &= 137.33 \text{ amu} + (2 \times 14.01 \text{ amu}) + (6 \times 16.00 \text{ amu}) = 261.35 \text{ amu} \end{aligned}$$

In the next two sample problems, the name or molecular depiction is used to find a compound's molecular or formula mass.

SAMPLE PROBLEM 2.15 | Calculating the Molecular Mass of a Compound

Problem Using the periodic table, calculate the molecular (or formula) mass of

- Tetraphosphorus trisulfide
- Ammonium nitrate

Plan We first write the formula, then multiply the number of atoms (or ions) of each element by its atomic mass (from the periodic table), and find the sum.

Solution

- The formula is P₄S₃.

$$\begin{aligned} \text{Molecular mass} &= (4 \times \text{atomic mass of P}) + (3 \times \text{atomic mass of S}) \\ &= (4 \times 30.97 \text{ amu}) + (3 \times 32.06 \text{ amu}) \\ &= 220.06 \text{ amu} \end{aligned}$$

(b) The formula is NH_4NO_3 . We count the total number of N atoms, even though they belong to different ions:

Formula mass

$$\begin{aligned} &= (2 \times \text{atomic mass of N}) + (4 \times \text{atomic mass of H}) + (3 \times \text{atomic mass of O}) \\ &= (2 \times 14.01 \text{ amu}) + (4 \times 1.008 \text{ amu}) + (3 \times 16.00 \text{ amu}) \\ &= 80.05 \text{ amu} \end{aligned}$$

Check You can often find large errors by rounding atomic masses to the nearest 5 and adding: (a) $(4 \times 30) + (3 \times 30) = 210 \approx 220.06$. The sum has two decimal places because the atomic masses have two. (b) $(2 \times 15) + 4 + (3 \times 15) = 79 \approx 80.05$.

FOLLOW-UP PROBLEMS

2.15A What is the molecular (or formula) mass of each of the following?

- (a) Hydrogen peroxide
- (b) Cesium carbonate

2.15B What is the molecular (or formula) mass of each of the following?

- (a) Sulfuric acid
- (b) Copper(II) chlorate

SOME SIMILAR PROBLEMS 2.106–2.109

SAMPLE PROBLEM 2.16

Using Molecular Depictions to Determine Formula, Name, and Mass

Problem Each scene represents a binary compound. Determine its formula, name, and molecular (or formula) mass.

Plan Each of the compounds contains only two elements, so, to find the formula, we find the simplest whole-number ratio of one atom to the other. From the formula, we determine the name and the molecular (or formula) mass.

Solution (a) There is one purple sphere (sodium) for each green sphere (fluorine), so the formula is NaF . A metal and nonmetal form an ionic compound, in which the metal is named first: **sodium fluoride**.

$$\begin{aligned} \text{Formula mass} &= (1 \times \text{atomic mass of Na}) + (1 \times \text{atomic mass of F}) \\ &= 22.99 \text{ amu} + 19.00 \text{ amu} = 41.99 \text{ amu} \end{aligned}$$

(b) There are three green spheres (fluorine) for each blue sphere (nitrogen), so the formula is NF_3 . Two nonmetals form a covalent compound. Nitrogen has a lower group number, so it is named first: **nitrogen trifluoride**.

$$\begin{aligned} \text{Molecular mass} &= (1 \times \text{atomic mass of N}) + (3 \times \text{atomic mass of F}) \\ &= 14.01 \text{ amu} + (3 \times 19.00 \text{ amu}) = 71.01 \text{ amu} \end{aligned}$$

Check (a) Sodium is a Group 1 element, so Na forms a $1+$ ion; fluorine is a Group 17 element, so F forms a $1-$ ion. The charges balance with one Na^+ per F^- . Also, ionic compounds are solids, consistent with the picture. (b) Covalent compounds often occur as individual molecules, as in the picture. Rounding in (a) gives $25 + 20 = 45$; in (b), we get $15 + (3 \times 20) = 75$, so there are no large errors.

FOLLOW-UP PROBLEMS

2.16A Determine the name, formula, and molecular (or formula) mass of the compound in each scene below:

2.16B Determine the name, formula, and molecular (or formula) mass of the compound in each scene below:

SOME SIMILAR PROBLEMS 2.112, 2.113, and 2.115

Representing Molecules with Formulas and Models

In order to represent objects too small to see, chemists employ a variety of formulas and models. Each conveys different information, as shown for water:

- A *molecular formula* uses element symbols and, often, numerical subscripts to give the *actual* number of atoms of each element in a molecule of the compound. (Recall that, for ionic compounds, the *formula unit* gives the *relative* number of each type of ion.) The molecular formula of water is H_2O : there are two H atoms and one O atom in each molecule.

- A *structural formula* shows the relative placement and connections of atoms in the molecule. It uses symbols for the atoms *and* either a pair of dots (*electron-dot formula*, left) or a line (*bond-line formula*, right) to show the bonds between the atoms. In water, each H atom is bonded to the O atom, but not to the other H atom.

In models shown throughout this text, colored balls represent atoms.

- A *ball-and-stick model* shows atoms as balls and bonds as sticks, and the angles between the bonds are accurate. Note that water is a bent molecule (with a bond angle of 104.5°). This type of model doesn't show the bonded atoms overlapping or their accurate sizes, so it exaggerates the distance between them.
- A *space-filling model* is an accurately scaled-up image of the molecule, so it shows the relative sizes of the atoms, the relative distances between the nuclei (centers of the spheres), and the angles between the bonds. However, bonds are not shown, and it can be difficult to see each atom in a complex molecule.

Every molecule is minute, but the range of molecular sizes, and thus molecular masses, is enormous. Table 2.9 shows the two types of formulas and models for some diatomic and small polyatomic molecules, as well as a space-filling model of a portion of one extremely large molecule, called a *macromolecule*, deoxyribonucleic acid (DNA).

Table 2.9 | Representing Molecules

Name	Molecular Formula (Molecular Mass, in amu)	Structural Formula	Ball-and-Stick Model	Space-Filling Model
Carbon monoxide	CO (28.01)	$\text{C}\equiv\text{O}$		
Nitrogen dioxide	NO_2 (46.01)			
Aspirin (acetylsalicylic acid)	$\text{C}_9\text{H}_8\text{O}_4$ (180.15)			

Deoxyribonucleic acid (DNA) (~10,000,000 amu)

An Overview of the Components of Matter

Understanding matter at the observable and atomic scales is the essence of chemistry.

Figure 2.27 is a visual overview of many key terms and ideas in this chapter.

› Summary of Section 2.7

- › An ionic compound is named with cation first and anion second: metal name + nonmetal root + *-ide*. For metals that can form more than one ion, the charge is shown with a roman numeral: metal name(charge) + nonmetal root + *-ide*.
- › Oxoanions have suffixes, and sometimes prefixes, attached to the root of the element name to indicate the number of oxygen atoms.
- › Names of hydrates have a numerical prefix indicating the number of associated water molecules.
- › Acid names are based on anion names.
- › For binary covalent compounds, the first word of the name is the element farther left or lower down in the periodic table, and prefixes show the numbers of each atom.

- › The molecular (or formula) mass of a compound is the sum of the atomic masses.
- › Chemical formulas give the number of atoms (molecular) or the arrangement of atoms (structural) of one unit of a compound.
- › Molecular models convey information about bond angles (ball-and-stick) and relative atomic sizes and distances between atoms (space-filling).

Figure 2.27 The classification of matter from a chemical point of view.

CHAPTER REVIEW GUIDE

Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

Understand These Concepts

1. The defining characteristics of the three types of matter—element, compound, and mixture—on the macroscopic and atomic levels, and of the particles within them—atoms, molecules, and ions (§2.1)
2. The types of mixtures and their properties (§2.1)
3. The significance of the three mass laws—mass conservation, definite composition, and multiple proportions (§2.2)
4. The postulates of Dalton's atomic theory and how it explains the mass laws (§2.2)
5. The major contribution of experiments by Thomson, Millikan, and Rutherford to our understanding of atomic structure (§2.3)
6. The structure of the atom, the main features of the subatomic particles, and the importance of isotopes in determining atomic mass (§2.4)
7. The format of the periodic table and the general location and characteristics of metals, metalloids, and nonmetals (§2.5)
8. The essential features of ionic and covalent compounds and the distinction between them (§2.6)

Master These Skills

1. Distinguishing elements, compounds, and mixtures at the atomic scale (SP 2.1)
2. Using the mass ratio of element to compound to find the mass of an element in a compound (SP 2.2)
3. Visualizing the mass laws (SP 2.3)
4. Determining the numbers of subatomic particles in the isotopes of an element (SP 2.4)
5. Calculating an atomic mass from isotopic composition (SP 2.5)
6. Identifying an element from its Z value (SP 2.6)
7. Predicting the ion an element forms (SP 2.7)
8. Naming and writing the formula of an ionic compound formed from the ions in Tables 2.4–2.6 (SPs 2.8–2.11, 2.16)
9. Naming and writing the formula of an acid and its anion (SP 2.12)
10. Naming and writing the formula of a binary covalent compound (SPs 2.13, 2.14, 2.16)
11. Calculating the molecular or formula mass of a compound (SP 2.15, 2.16)

Key Terms

Page numbers appear in parentheses.

anion (64)	covalent compound (64)	ion (64)	monatomic ion (65)
atom (42)	crystallization (44)	ionic compound (64)	neutron (n^0) (55)
atomic mass (59)	dalton (Da) (58)	isotopes (57)	nonmetal (62)
atomic mass unit (amu) (58)	distillation (44)	isotopic mass (59)	nucleus (55)
atomic number (Z) (56)	electron (e^-) (55)	law of definite (or constant) composition (48)	oxoanion (71)
atomic symbol (57)	element (42)	law of mass conservation (46)	percent by mass (mass percent, mass %) (47)
binary covalent compound (74)	filtration (44)	law of multiple proportions (49)	period (61)
binary ionic compound (64)	formula mass (76)	mass number (A) (56)	periodic table of the elements (61)
cathode ray (52)	formula unit (76)	mass spectrometry (58)	polyatomic ion (67)
cation (64)	fraction by mass (mass fraction) (47)	metal (62)	proton (p^+) (55)
chemical bond (64)	group (61)	metalloid (semimetal) (62)	substance (41)
chemical formula (68)	heterogeneous mixture (43)	mixture (41)	volatility (44)
chromatography (44)	homogeneous mixture (solution) (43)	molecular mass (76)	
compound (42)	hydrate (71)	molecule (42)	
covalent bond (66)			

Key Equations and Relationships

Page numbers appear in parentheses.

2.1 Finding the mass of an element in a given mass of compound (48):

$$\text{Mass of element in sample} = \text{mass of compound in sample} \times \frac{\text{mass of element in compound}}{\text{mass of compound}}$$

2.2 Calculating the number of neutrons in an atom (57):

$$\text{Number of neutrons} = \text{mass number} - \text{atomic number}$$

or, $N = A - Z$

2.3 Calculating the average atomic mass of the isotopes of an element (59):

$$\text{Atomic mass} = \Sigma(\text{isotopic mass})(\text{fractional abundance of isotope})$$

2.4 Determining the molecular mass of a formula unit of a compound (76):

$$\text{Molecular mass or formula mass} = \text{sum of atomic masses}$$

CHAPTER PRACTICE TEST

The answers to the Practice Test problems are shown below and the full solutions can be found in the e-book.

1. Which of the following **two** statements are *not* correct? Select **both** answers.

- (a) The atomic number gives the number of electrons in a neutral atom.
- (b) SrF_2 is an ionic compound.
- (c) Group 16 nonmetals have a charge of $2-$ in binary ionic compounds.
- (d) The inner transition elements are all metals.
- (e) In the compound carbon tetrachloride, carbon forms ions with a $4+$ charge.
- (f) Mixtures and compounds can be separated into their pure component substances by physical means.

2. How many protons, neutrons, and electrons does $^{90}\text{Zr}^{3+}$ have?

- (a) 50 protons, 40 neutrons, and 47 electrons
- (b) 40 protons, 50 neutrons, and 40 electrons
- (c) 50 protons, 50 neutrons, and 53 electrons
- (d) 40 protons, 50 neutrons, and 43 electrons
- (e) 40 protons, 50 neutrons, and 37 electrons
- (f) 43 protons, 90 neutrons, and 40 electrons

3. What is the formula of cobalt(III) sulfite?

- (a) CoSO_4
- (b) Co_2S_3
- (c) $\text{Co}_2(\text{SO}_3)_3$
- (d) $\text{Co}_2(\text{SO}_4)_3$
- (e) $\text{Co}_3(\text{SO}_3)_2$
- (f) Co_3S_2

4. A metallic element forms an ionic compound with bromine, having the formula XBr_4 . This ion of element X has 70 electrons. What is the identity of the element?

- (a) Yb
- (b) Hf
- (c) Pb
- (d) Ho
- (e) W

5. Which is the correct formula for the compound formed between the 6th period alkali metal and the hypobromite ion?

- (a) Rb_2BrO_3
- (b) $\text{Sr}(\text{BrO}_2)_2$
- (c) CsBrO_2
- (d) RbBrO
- (e) $\text{Ba}(\text{BrO})_2$
- (f) CsBrO

6. **Two** of the following compounds are incorrectly named. Select **both** compounds that are incorrectly named.

- (a) CuF_2 copper(II) fluoride
- (b) As_4O_6 tetraarsenic hexoxide
- (c) AlCl_3 aluminum chlorite
- (d) K_3PO_4 potassium phosphide
- (e) H_2SO_3 sulfurous acid

7. A compound is composed of carbon, hydrogen, and oxygen. If a sample of the compound has a mass of 171.2 g and the compound is 42.1% carbon and 51.4% oxygen, what is the mass of hydrogen in the sample?

- (a) 6.50 g
- (b) 11.1 g
- (c) 18.7 g
- (d) 21.4 g
- (e) 26.3 g

8. Calcium has five stable isotopes: ^{40}Ca (39.96 amu), ^{42}Ca (41.96 amu), ^{43}Ca (42.96 amu), ^{44}Ca (43.96 amu), and ^{46}Ca (45.96 amu). Which one of these isotopes is the most abundant?

- (a) ^{40}Ca
- (b) ^{42}Ca
- (c) ^{43}Ca
- (d) ^{44}Ca
- (e) ^{46}Ca

9. The element antimony has two naturally occurring isotopes: ^{121}Sb and ^{123}Sb . Given that the isotopic masses of these two isotopes are 120.9038 amu and 122.9042 amu, respectively, and the average atomic mass of antimony is 121.76 amu, calculate the percent abundance of ^{121}Sb .

- (a) 42.80%
- (b) 57.20%
- (c) 32.12%
- (d) 66.54%
- (e) 61.42%

10. A sample of a compound contains 2.04 kg of aluminum and 1.81 kg of oxygen. What mass of aluminum is in a 7.11 kg sample of the compound?

- (a) 3.56 kg
- (b) 3.14 kg
- (c) 3.77 kg
- (d) 4.11 kg
- (e) 5.02 kg

Answers: 1. e, f; 2. e; 3. c; 4. e; 5. f; 6. c, d; 7. b; 8. a; 9. b; 10. c

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

2.1A (a) There is only one type of atom (*blue*) present, so this is an element. (b) Two different atoms (*orange* and *green*) appear in a fixed ratio of 1/1, so this is a compound. (c) These molecules consist of one type of atom (*orange*), so this is an element.

2.1B There are two types of particles reacting (*left circle*), one with two blue atoms and the other with two orange; the depiction shows a mixture of two elements. In the product (*right circle*), all the particles have one blue atom and one orange; this is a compound.

2.2A Mass (g) of fool's gold

$$= 86.2 \text{ g iron} \times \frac{110.0 \text{ g fool's gold}}{51.2 \text{ g iron}}$$

$$= 185 \text{ g fool's gold}$$

$$\text{Mass (g) of sulfur} = 185 \text{ g fool's gold} - 86.2 \text{ g iron}$$

$$= 98.8 \text{ g sulfur}$$

2.2B Mass (g) of silver

$$= 3.57 \text{ g silver bromide} \times \frac{15.4 \text{ g silver}}{26.8 \text{ g silver bromide}}$$

$$= 2.05 \text{ g silver}$$

$$\text{Mass (g) of bromine} = 3.57 \text{ g silver bromide} - 2.05 \text{ g silver}$$

$$= 1.52 \text{ g bromine}$$

2.3A There are 12 black atoms and 14 red atoms in each circle (mass conservation). In the right circle, there are molecules of two compounds—one compound has one black and one red atom, and the other has one black and two red atoms (multiple proportions). Each compound has a fixed ratio of black-to-red atoms (definite composition).

2.3B Sample B. Two bromine-fluorine compounds appear. In one, there are three fluorine atoms for each bromine; in the other, there is one fluorine for each bromine. Therefore, the masses of fluorine that combine with a given mass of bromine are in a 3/1 ratio.

2.4A Titanium has an atomic number of 22. Mass number – 22 = number of neutrons.

^{46}Ti has 22p^+ , 22e^- , and $(46 - 22) = 24\text{n}^0$.

^{47}Ti has 22p^+ , 22e^- , and $(47 - 22) = 25\text{n}^0$.

^{48}Ti has 22p^+ , 22e^- , and $(48 - 22) = 26\text{n}^0$.

^{49}Ti has 22p^+ , 22e^- , and $(49 - 22) = 27\text{n}^0$.

^{50}Ti has 22p^+ , 22e^- , and $(50 - 22) = 28\text{n}^0$.

2.4B (a) Mass number – number of neutrons = $88 - 50 = 38$ = atomic number. The element is strontium. (b) Mass number – atomic number = $86 - 38 = 48$ = number of neutrons.

2.5A First, divide the percent abundance value by 100 to obtain the fractional value for each isotope. Multiply each isotopic mass by the fractional value, and add the resulting masses to obtain silicon's atomic mass:

Atomic mass of Si

$$\begin{aligned} &= (\text{isotopic mass of } ^{28}\text{Si})(\text{fractional abundance of } ^{28}\text{Si}) \\ &\quad + (\text{isotopic mass of } ^{29}\text{Si})(\text{fractional abundance of } ^{29}\text{Si}) \\ &\quad + (\text{isotopic mass of } ^{30}\text{Si})(\text{fractional abundance of } ^{30}\text{Si}) \\ &= (27.97693 \text{ amu})(0.9223) + 28.976495 \text{ amu}(0.0467) \\ &\quad + (29.973770 \text{ amu})(0.0310) \\ &= 28.09 \text{ amu} \end{aligned}$$

2.5B $10.0129x + [11.0093(1 - x)] = 10.81$; $0.9964x = 0.1993$; $x = 0.2000$ and $1 - x = 0.8000$; percent abundance of $^{10}\text{B} = 20.00\%$; percent abundance of $^{11}\text{B} = 80.00\%$

2.6A (a) Silicon, Si; Group 14 and Period 3; metalloid
(b) Cesium, Cs; Group 1 and Period 6; main-group metal
(c) Xenon, Xe; Group 18 and Period 5; nonmetal

2.6B (a) Magnesium, Mg; Group 2 and Period 3; main-group metal
(b) Nitrogen, N; Group 15 and Period 2; nonmetal
(c) Zinc, Zn; Group 12 and Period 4; transition metal

2.7A (a) S^{2-} ; (b) Rb^+ ; (c) Ba^{2+}

2.7B (a) Mg; (b) Br; (c) O

2.8A (a) Zinc oxide, ZnO; (b) silver bromide, AgBr; (c) lithium chloride LiCl; (d) aluminum sulfide, Al_2S_3

2.8B (a) Potassium sulfide, K_2S ; (b) barium iodide, BaI_2 ;
(c) cesium nitride, Cs_3N ; (d) sodium hydride, NaH

2.9A (a) PbO_2 ; (b) copper(I) sulfide (cuprous sulfide); (c) iron(II) bromide (ferrous bromide); (d) HgCl_2

2.9B (a) Cu_3N_2 ; (b) lead(II) iodide; (c) Cr_2S_3 ; (d) iron(II) oxide

2.10A (a) $\text{Cu}(\text{NO}_3)_2 \cdot 3\text{H}_2\text{O}$; (b) $\text{Zn}(\text{OH})_2$; (c) lithium cyanide

2.10B (a) $(\text{NH}_4)_2\text{SO}_4$; (b) nickel(II) nitrate hexahydrate; (c) KHCO_3

2.11A (a) $(\text{NH}_4)_3\text{PO}_4$; ammonium is NH_4^+ and phosphate is PO_4^{3-} .
(b) $\text{Al}(\text{OH})_3$; parentheses are needed around the polyatomic ion OH^- .

(c) Magnesium hydrogen carbonate; Mg^{2+} is magnesium and can have only a 2+ charge, so (II) is not needed in the name; HCO_3^- is hydrogen carbonate (or bicarbonate).

2.11B (a) Chromium(III) nitrate; the *-ic* ending is not used with roman numerals; NO_3^- is nitrate.

(b) Calcium nitrite; Ca^{2+} is calcium and NO_2^- is nitrite.

(c) KClO_3 ; potassium is K^+ and chlorate is ClO_3^- ; parentheses are not needed when only one polyatomic ion is present.

2.12A (a) ClO_3^- , chlorate; (b) F^- , fluoride; (c) CH_3COO^- (or $\text{C}_2\text{H}_3\text{O}_2^-$), acetate; (d) NO_2^- , nitrite

2.12B (a) Sulfurous acid; add one H^+ ion to hydrogen sulfite, HSO_3^- , or two H^+ to sulfite, SO_3^{2-} ; (b) hypobromous acid, hypobromite, BrO^- ; (c) chlorous acid, chlorite, ClO_2^- ;
(d) hydriodic acid, iodide, I^-

2.13A (a) Sulfur trioxide; (b) silicon dioxide; (c) N_2O ; (d) SeF_6

2.13B (a) Sulfur dichloride; (b) dinitrogen pentoxide;
(c) BF_3 ; (d) IBr_3

2.14A (a) Disulfur dichloride; the *-ous* suffix is not used.

(b) NO; the name indicates one nitrogen.

(c) Bromine trichloride; Br is in a higher period in Group 17, so it is named first.

2.14B (a) Tetraphosphorus hexoxide; the name of the element phosphorus ends in *-us* not *-ous*, and the prefix *hexa-* is shortened to *hex-* before *oxide*. (b) Sulfur hexafluoride; sulfur has a lower group number, so it comes first, and fluorine gets the *-ide* ending. (c) NBr_3 ; nitrogen's symbol is N, and the second letter of a symbol is lowercase: bromine is Br.

2.15A (a) Hydrogen peroxide is H_2O_2 .

Molecular mass

$$\begin{aligned} &= (2 \times \text{atomic mass of H}) + (2 \times \text{atomic mass of O}) \\ &= (2 \times 1.008 \text{ amu}) + (2 \times 16.00 \text{ amu}) = 34.02 \text{ amu} \end{aligned}$$

(b) Cesium carbonate is Cs_2CO_3 .

Formula mass

$$\begin{aligned} &= (2 \times \text{atomic mass of Cs}) + (1 \times \text{atomic mass of C}) \\ &\quad + (3 \times \text{atomic mass of O}) \\ &= (2 \times 132.91 \text{ amu}) + 12.01 \text{ amu} + (3 \times 16.00 \text{ amu}) \\ &= 325.83 \text{ amu} \end{aligned}$$

2.15B (a) Sulfuric acid is H_2SO_4 .

Molecular mass

$$\begin{aligned} &= (2 \times \text{atomic mass of H}) + (1 \times \text{atomic mass of S}) \\ &\quad + (4 \times \text{atomic mass of O}) \\ &= (2 \times 1.008 \text{ amu}) + 32.06 \text{ amu} + (4 \times 16.00 \text{ amu}) \\ &= 98.08 \text{ amu} \end{aligned}$$

(b) Copper(II) chlorate is $\text{Cu}(\text{ClO}_3)_2$.

Formula mass

$$\begin{aligned} &= (1 \times \text{atomic mass of Cu}) + (2 \times \text{atomic mass of Cl}) \\ &\quad + (6 \times \text{atomic mass of O}) \\ &= (1 \times 63.55 \text{ amu}) + (2 \times 35.45 \text{ amu}) + (6 \times 16.00 \text{ amu}) \\ &= 230.45 \text{ amu} \end{aligned}$$

2.16A (a) Na_2O . This is an ionic compound, so the name is sodium oxide.

Formula mass

$$\begin{aligned} &= (2 \times \text{atomic mass of Na}) + (1 \times \text{atomic mass of O}) \\ &= (2 \times 22.99 \text{ amu}) + 16.00 \text{ amu} = 61.98 \text{ amu} \end{aligned}$$

(b) NO_2 . This is a covalent compound, and N has the lower group number, so the name is nitrogen dioxide.

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS (continued)

Molecular mass

$$= (1 \times \text{atomic mass of N}) + (2 \times \text{atomic mass of O})$$

$$= 14.01 \text{ amu} + (2 \times 16.00 \text{ amu}) = 46.01 \text{ amu}$$

2.16B (a) Magnesium chloride, MgCl_2

Formula mass

$$= (1 \times \text{atomic mass of Mg}) + (2 \times \text{atomic mass of Cl})$$

$$= (1 \times 24.30 \text{ amu}) + (2 \times 35.45 \text{ amu}) = 95.20 \text{ amu}$$

(b) Chlorine trifluoride, ClF_3

Molecular mass

$$= (1 \times \text{atomic mass of Cl}) + (3 \times \text{atomic mass of F})$$

$$= 35.45 \text{ amu} + (3 \times 19.00 \text{ amu}) = 92.45 \text{ amu}$$

PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

Elements, Compounds, and Mixtures: An Atomic Overview (Sample Problem 2.1)

Concept Review Questions

2.1 What is the key difference between an element and a compound?

2.2 List two differences between a compound and a mixture.

2.3 Which of the following are pure substances? Explain.

- (a) Calcium chloride, used to melt ice on roads, consists of two elements, calcium and chlorine, in a fixed mass ratio.
 (b) Sulfur consists of sulfur atoms combined into octatomic molecules.
 (c) Baking powder, a leavening agent, contains 26–30% sodium hydrogen carbonate and 30–35% calcium dihydrogen phosphate by mass.
 (d) Cytosine, a component of DNA, consists of H, C, N, and O atoms bonded in a specific arrangement.

2.4 Classify each substance in Problem 2.3 as an element, a compound, or a mixture, and explain your answers.

2.5 Explain the following statement: The smallest particles unique to an element may be atoms or molecules.

2.6 Explain the following statement: The smallest particles unique to a compound cannot be atoms.

2.7 Can the relative amounts of the components of a mixture vary? Can the relative amounts of the components of a compound vary? Explain.

2.8 In what main way is separating the components of a mixture different from separating the components of a compound?

2.9 What is the difference between a homogeneous and a heterogeneous mixture?

2.10 Is a solution a homogeneous or a heterogeneous mixture?

Skill-Building Exercises (grouped in similar pairs)

2.11 Classify each of the following as a compound, a homogeneous mixture, or a heterogeneous mixture: (a) distilled water; (b) gasoline; (c) beach sand; (d) wine; (e) air.

2.12 Classify each of the following as a compound, a homogeneous mixture, or a heterogeneous mixture: (a) orange juice; (b) vegetable soup; (c) cement; (d) calcium sulfate; (e) tea.

Problems in Context

2.13 The tap water found in many areas of the United States leaves white deposits when it evaporates. Is this tap water a mixture or a compound? Explain.

2.14 Each scene below represents a mixture. Describe each one in terms of the number(s) of elements and/or compounds present.

2.15 Samples of illicit “street” drugs often contain an inactive component, such as ascorbic acid (vitamin C). After obtaining a sample of cocaine, government chemists calculate the mass of vitamin C per gram of drug sample and use it to track the drug’s distribution. For example, if different samples of cocaine obtained on the streets of New York, Los Angeles, and Paris all contain 0.6384 g of vitamin C per gram of sample, they very likely come from a common source. Do these street samples consist of a compound, an element, or a mixture? Explain.

2.16 Name the technique(s) and briefly describe the procedure for separating each of the following mixtures into pure components: (a) table salt and pepper; (b) drinking water contaminated with soot; (c) crushed ice and crushed glass; (d) table sugar dissolved in ethanol; (e) two pigments (chlorophyll *a* and chlorophyll *b*) from spinach leaves.

2.17 Which separation method is operating in each of the following procedures?

- (a) Pouring a mixture of cooked pasta and boiling water into a colander
- (b) Removing colored impurities from raw sugar to make refined sugar

2.18 A quality-control laboratory analyzes a product mixture using gas-liquid chromatography. The separation of components is more than adequate, but the process takes too long. Suggest two ways, other than changing the stationary phase, to shorten the analysis time.

The Observations That Led to an Atomic View of Matter

(Sample Problems 2.2 and 2.3)

Concept Review Questions

2.19 Why was it necessary for separation techniques and methods of chemical analysis to be developed before the laws of definite composition and multiple proportions could be formulated?

2.20 To which class(es) of matter—elements, compounds, and/or mixtures—do the following apply: (a) law of mass conservation; (b) law of definite composition; (c) law of multiple proportions?

2.21 In our modern view of matter and energy, is the law of mass conservation still relevant to chemical reactions? Explain.

2.22 Identify the mass law that each of the following observations demonstrates, and explain your reasoning:

- (a) A sample of potassium chloride from Chile contains the same percent by mass of potassium as one from Poland.
- (b) A flashbulb contains magnesium and oxygen before use and magnesium oxide afterward, but its mass does not change.
- (c) Arsenic and oxygen form one compound that is 65.2 mass % arsenic and another that is 75.8 mass % arsenic.

2.23 Which of the following scenes illustrate(s) the fact that compounds of chlorine (*green*) and oxygen (*red*) exhibit the law of multiple proportions? Name the compounds.

2.24 (a) Does the percent by mass of each element in a compound depend on the amount of compound? Explain.

(b) Does the mass of each element in a compound depend on the amount of compound? Explain.

2.25 Does the percent by mass of each element in a compound depend on the amount of that element used to make the compound? Explain.

Skill-Building Exercises (grouped in similar pairs)

2.26 State the mass law(s) demonstrated by the following experimental results, and explain your reasoning:

Experiment 1: A student heats 1.00 g of a blue compound and obtains 0.64 g of a white compound and 0.36 g of a colorless gas.

Experiment 2: A second student heats 3.25 g of the same blue compound and obtains 2.08 g of a white compound and 1.17 g of a colorless gas.

2.27 State the mass law(s) demonstrated by the following experimental results, and explain your reasoning:

Experiment 1: A student heats 1.27 g of copper and 3.50 g of iodine to produce 3.81 g of a white compound; 0.96 g of iodine remains.

Experiment 2: A second student heats 2.55 g of copper and 3.50 g of iodine to form 5.25 g of a white compound; 0.80 g of copper remains.

2.28 Fluorite, a mineral of calcium, is a compound of the metal with fluorine. Analysis shows that a 2.76-g sample of fluorite contains 1.42 g of calcium. Calculate the (a) mass of fluorine in the sample; (b) mass fractions of calcium and fluorine in fluorite; (c) mass percents of calcium and fluorine in fluorite.

2.29 Galena, a mineral of lead, is a compound of the metal with sulfur. Analysis shows that a 2.34-g sample of galena contains 2.03 g of lead. Calculate the (a) mass of sulfur in the sample; (b) mass fractions of lead and sulfur in galena; (c) mass percents of lead and sulfur in galena.

2.30 Magnesium oxide (MgO) forms when the metal burns in air. (a) If 1.25 g of MgO contains 0.754 g of Mg, what is the mass ratio of magnesium to magnesium oxide? (b) How many grams of Mg are in 534 g of MgO?

2.31 Zinc sulfide (ZnS) occurs in the zincblende crystal structure. (a) If 2.54 g of ZnS contains 1.70 g of Zn, what is the mass ratio of zinc to zinc sulfide? (b) How many kilograms of Zn are in 3.82 kg of ZnS?

2.32 A compound of copper and sulfur contains 88.39 g of metal and 44.61 g of nonmetal. How many grams of copper are in 5264 kg of compound? How many grams of sulfur?

2.33 A compound of iodine and cesium contains 63.94 g of metal and 61.06 g of nonmetal. How many grams of cesium are in 38.77 g of compound? How many grams of iodine?

2.34 Show, with calculations, how the following data illustrate the law of multiple proportions:

Compound 1: 47.5 mass % sulfur and 52.5 mass % chlorine

Compound 2: 31.1 mass % sulfur and 68.9 mass % chlorine

2.35 Show, with calculations, how the following data illustrate the law of multiple proportions:

Compound 1: 77.6 mass % xenon and 22.4 mass % fluorine

Compound 2: 63.3 mass % xenon and 36.7 mass % fluorine

Problems in Context

2.36 Dolomite is a carbonate of magnesium and calcium. Analysis shows that 7.81 g of dolomite contains 1.70 g of Ca. Calculate the mass percent of Ca in dolomite. On the basis of the mass percent of Ca, and neglecting all other factors, which is the richer source of Ca, dolomite or fluorite (see Problem 2.28)?

2.37 The mass percent of sulfur in a sample of coal is a key factor in the environmental impact of the coal because the sulfur

combines with oxygen when the coal is burned and the oxide can then be incorporated into acid rain. Which of the following coals would have the smallest environmental impact?

	Mass (g) of Sample	Mass (g) of Sulfur in Sample
Coal A	378	11.3
Coal B	495	19.0
Coal C	675	20.6

The Observations That Led to the Nuclear Atom Model

Concept Review Questions

2.38 Thomson was able to determine the charge/mass ratio of the electron but not its mass. How did Millikan's experiment allow determination of the electron's mass?

2.39 The following charges on individual oil droplets were obtained during an experiment similar to Millikan's: -3.204×10^{-19} C; -4.806×10^{-19} C; -8.010×10^{-19} C; -1.442×10^{-18} C. Determine a charge for the electron (in C, coulombs), and explain your answer.

2.40 Describe Thomson's model of the atom. How might it account for the production of cathode rays?

2.41 When Rutherford's coworkers bombarded gold foil with α particles, they obtained results that overturned the existing (Thomson) model of the atom. Explain.

The Atomic Theory Today

(Sample Problems 2.4 and 2.5)

Concept Review Questions

2.42 Define *atomic number* and *mass number*. Which can vary without changing the identity of the element?

2.43 Choose the correct answer. The difference between the mass number of an isotope and its atomic number is (a) directly related to the identity of the element; (b) the number of electrons; (c) the number of neutrons; (d) the number of isotopes.

2.44 Even though several elements have only one naturally occurring isotope and all atomic nuclei have whole numbers of protons and neutrons, no atomic mass is a whole number. Use the data from Table 2.2 to explain this fact.

2.45 Chlorine has two naturally occurring isotopes, ^{35}Cl (abundance 76%) and ^{37}Cl (abundance 24%), and it occurs as diatomic (two-atom) molecules. In a mass spectrum, peaks are seen for the molecule and for the separated atoms.

- (a) How many peaks are in the mass spectrum?
 (b) What is the m/e value for the heaviest particle and for the lightest particle?

Skill-Building Exercises (grouped in similar pairs)

2.46 Argon has three naturally occurring isotopes, ^{36}Ar , ^{38}Ar , and ^{40}Ar . What is the mass number of each isotope? How many protons, neutrons, and electrons are present in each?

2.47 Chlorine has two naturally occurring isotopes, ^{35}Cl and ^{37}Cl . What is the mass number of each isotope? How many protons, neutrons, and electrons are present in each?

2.48 Do both members of the following pairs have the same number of protons? Neutrons? Electrons?

- (a) ^{16}O and ^{17}O (b) ^{40}Ar and ^{41}K (c) ^{60}Co and ^{60}Ni

Which pair(s) consist(s) of atoms with the same Z value? N value? A value?

2.49 Do both members of the following pairs have the same number of protons? Neutrons? Electrons?

- (a) ^1H and ^3He (b) ^{14}C and ^{15}N (c) ^{19}F and ^{18}F

Which pair(s) consist(s) of atoms with the same Z value? N value? A value?

2.50 Write the ^A_ZX notation for each atomic depiction:

2.51 Write the ^A_ZX notation for each atomic depiction:

2.52 Draw atomic depictions similar to those in Problem 2.50 for (a) $^{48}_{22}\text{Ti}$; (b) $^{79}_{34}\text{Se}$; (c) $^{11}_5\text{B}$.

2.53 Draw atomic depictions similar to those in Problem 2.50 for (a) $^{207}_{82}\text{Pb}$; (b) ^9_4Be ; (c) $^{75}_{33}\text{As}$.

2.54 Gallium has two naturally occurring isotopes, ^{69}Ga (isotopic mass = 68.9256 amu, abundance = 60.11%) and ^{71}Ga (isotopic mass = 70.9247 amu, abundance = 39.89%). Calculate the atomic mass of gallium.

2.55 Magnesium has three naturally occurring isotopes, ^{24}Mg (isotopic mass = 23.9850 amu, abundance = 78.99%), ^{25}Mg (isotopic mass = 24.9858 amu, abundance = 10.00%), and ^{26}Mg (isotopic mass = 25.9826 amu, abundance = 11.01%). Calculate the atomic mass of magnesium.

2.56 Chlorine has two naturally occurring isotopes, ^{35}Cl (isotopic mass = 34.9689 amu) and ^{37}Cl (isotopic mass = 36.9659 amu). If chlorine has an atomic mass of 35.4527 amu, what is the percent abundance of each isotope?

2.57 Copper has two naturally occurring isotopes, ^{63}Cu (isotopic mass = 62.9296 amu) and ^{65}Cu (isotopic mass = 64.9278 amu). If copper has an atomic mass of 63.546 amu, what is the percent abundance of each isotope?

Elements: A First Look at the Periodic Table

(Sample Problem 2.6)

Concept Review Questions

2.58 How can iodine ($Z = 53$) have a higher atomic number yet a lower atomic mass than tellurium ($Z = 52$)?

2.59 Correct each of the following statements:

- (a) In the modern periodic table, the elements are arranged in order of increasing atomic mass.
- (b) Elements in a period have similar chemical properties.
- (c) Elements can be classified as either metalloids or nonmetals.

2.60 What class of elements lies along the “staircase” line in the periodic table? How do the properties of these elements compare with those of metals and nonmetals?

2.61 What are some characteristic properties of elements to the left of the elements along the “staircase”? To the right?

2.62 The elements in Groups 1 and 17 are all quite reactive. What is a major difference between them?

Skill-Building Exercises (grouped in similar pairs)

2.63 Give the name, atomic symbol, and group number of the element with each Z value, and classify it as a metal, metalloid, or nonmetal:

- (a) $Z = 32$ (b) $Z = 15$ (c) $Z = 2$ (d) $Z = 3$ (e) $Z = 42$

2.64 Give the name, atomic symbol, and group number of the element with each Z value, and classify it as a metal, metalloid, or nonmetal:

- (a) $Z = 33$ (b) $Z = 20$ (c) $Z = 35$ (d) $Z = 19$ (e) $Z = 13$

2.65 Fill in the blanks:

- (a) The symbol and atomic number of the heaviest alkaline earth metal are _____ and _____.
- (b) The symbol and atomic number of the lightest metalloid in Group 14 are _____ and _____.
- (c) Group 11 consists of the *coinage metals*. The symbol and atomic mass of the coinage metal whose atoms have the fewest electrons are _____ and _____.
- (d) The symbol and atomic mass of the halogen in Period 4 are _____ and _____.

2.66 Fill in the blanks:

- (a) The symbol and atomic number of the heaviest nonradioactive noble gas are _____ and _____.
- (b) The symbol and group number of the Period 5 transition element whose atoms have the fewest protons are _____ and _____.
- (c) The elements in Group 16 are sometimes called the *chalcogens*. The symbol and atomic number of the first metallic chalcogen are _____ and _____.
- (d) The symbol and number of protons of the Period 4 alkali metal atom are _____ and _____.

Compounds: Introduction to Bonding

(Sample Problem 2.7)

Concept Review Questions

2.67 Describe the type and nature of the bonding that occurs between reactive metals and nonmetals.

2.68 Describe the type and nature of the bonding that often occurs between two nonmetals.

2.69 How can ionic compounds be neutral if they consist of positive and negative ions?

2.70 Are molecules present in a sample of BaF_2 ? Explain.

2.71 Are ions present in a sample of P_4O_6 ? Explain.

2.72 The monatomic ions of Groups 1 and 17 are all singly charged. In what major way do they differ? Why?

2.73 Describe the formation of solid magnesium chloride (MgCl_2) from large numbers of magnesium and chlorine atoms.

2.74 Describe the formation of solid potassium sulfide (K_2S) from large numbers of potassium and sulfur atoms.

2.75 Does potassium nitrate (KNO_3) incorporate ionic bonding, covalent bonding, or both? Explain.

Skill-Building Exercises (grouped in similar pairs)

2.76 What monatomic ions would you expect potassium ($Z = 19$) and bromine ($Z = 35$) to form?

2.77 What monatomic ions would you expect radium ($Z = 88$) and selenium ($Z = 34$) to form?

2.78 For each ionic depiction, give the name of the parent atom, its mass number, and its group and period numbers:

2.79 For each ionic depiction, give the name of the parent atom, its mass number, and its group and period numbers:

2.80 An ionic compound forms when lithium ($Z = 3$) reacts with oxygen ($Z = 8$). If a sample of the compound contains 8.4×10^{21} lithium ions, how many oxide ions does it contain?

2.81 An ionic compound forms when calcium ($Z = 20$) reacts with iodine ($Z = 53$). If a sample of the compound contains 7.4×10^{21} calcium ions, how many iodide ions does it contain?

Compounds: Formulas, Names, and Masses

(Sample Problems 2.8 to 2.16)

Concept Review Questions

2.82 What information about the relative numbers of ions and the percent masses of elements is contained in the formula MgF_2 ?

2.83 How is a structural formula similar to a molecular formula? How is it different?

2.84 Consider a mixture of 10 billion O_2 molecules and 10 billion H_2 molecules. In what way is this mixture similar to a sample containing 10 billion hydrogen peroxide (H_2O_2) molecules? In what way is it different?

2.85 For what type(s) of compound do we use roman numerals in the names?

2.86 For what type(s) of compound do we use Greek numerical prefixes in the names?

2.87 For what type of compound are we unable to write a molecular formula?

Skill-Building Exercises (grouped in similar pairs)

2.88 Give the name and formula of the compound formed from each pair of elements: (a) sodium and nitrogen; (b) oxygen and strontium; (c) aluminum and chlorine.

2.89 Give the name and formula of the compound formed from each pair of elements: (a) cesium and bromine; (b) sulfur and barium; (c) calcium and fluorine.

2.90 Give the name and formula of the compound formed from each pair of elements:

(a) $_{12}\text{L}$ and $_{9}\text{M}$ (b) $_{30}\text{L}$ and $_{16}\text{M}$ (c) $_{17}\text{L}$ and $_{38}\text{M}$

2.91 Give the name and formula of the compound formed from each pair of elements:

(a) $_{37}\text{Q}$ and $_{35}\text{R}$ (b) $_{8}\text{Q}$ and $_{13}\text{R}$ (c) $_{20}\text{Q}$ and $_{53}\text{R}$

2.92 Give the systematic names for the formulas or the formulas for the names: (a) tin(IV) chloride; (b) FeBr_3 ; (c) cuprous bromide; (d) Mn_2O_3 .

2.93 Give the systematic names for the formulas or the formulas for the names: (a) CoO ; (b) mercury(I) chloride; (c) chromic oxide; (d) CuBr_2 .

2.94 Give the systematic names for the formulas or the formulas for the names: (a) Na_2HPO_4 ; (b) ammonium perchlorate; (c) $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2 \cdot 3\text{H}_2\text{O}$; (d) sodium nitrite.

2.95 Give the systematic names for the formulas or the formulas for the names: (a) $\text{Sn}(\text{SO}_3)_2$; (b) potassium dichromate; (c) FeCO_3 ; (d) potassium carbonate dihydrate.

2.96 Correct each of the following formulas:

(a) Barium oxide is BaO_2 .
 (b) Iron(II) nitrate is $\text{Fe}(\text{NO}_3)_3$.
 (c) Magnesium sulfide is MnSO_3 .
 (d) Potassium iodide is P_2I_3 .

2.97 Correct each of the following names:

(a) CuI is cobalt(II) iodide.
 (b) $\text{Fe}(\text{HSO}_4)_3$ is iron(II) sulfate.
 (c) MgCr_2O_7 is magnesium dichromium heptaoxide.
 (d) CaCl_2 is calcium(II) dichloride.

2.98 Give the name and formula for the acid derived from each of the following anions:

(a) hydrogen carbonate (b) IO_4^- (c) cyanide (d) HS^-

2.99 Give the name and formula for the acid derived from each of the following anions:

(a) perchlorate (b) NO_3^- (c) bromite (d) H_2PO_4^-

2.100 Many chemical names are similar at first glance. Give the formulas of the species in each set:

(a) Ammonium ion and ammonia
 (b) Magnesium sulfide, magnesium sulfite, and magnesium sulfate
 (c) Hydrochloric acid, chloric acid, and chlorous acid
 (d) Cuprous bromide and cupric bromide

2.101 Give the formulas of the compounds in each set:

(a) Lead(II) oxide and lead(IV) oxide
 (b) Lithium nitride, lithium nitrite, and lithium nitrate
 (c) Strontium hydride and strontium hydroxide
 (d) Magnesium oxide and manganese(II) oxide

2.102 Give the name and formula of the compound whose molecules consist of two sulfur atoms and four fluorine atoms.

2.103 Give the name and formula of the compound whose molecules consist of two chlorine atoms and one oxygen atom.

2.104 Correct each of the following formulas:

(a) Tetraphosphorus decoxide is P_4O_6 .
 (b) Diboron trioxide is B_3O_2 .
 (c) Phosphorus trifluoride is F_3P .

2.105 Correct each of the following names:

(a) CBr_4 is carbon bromide.
 (b) IF_7 is iodine pentafluoride.
 (c) NO is nitrogen(I) oxide.

2.106 Write the formula of each compound, and determine its molecular (formula) mass: (a) ammonium sulfate; (b) sodium dihydrogen phosphate; (c) potassium bicarbonate.

2.107 Write the formula of each compound, and determine its molecular (formula) mass: (a) sodium dichromate; (b) ammonium perchlorate; (c) magnesium nitrite trihydrate.

2.108 Calculate the molecular (formula) mass of each compound: (a) dinitrogen pentoxide; (b) lead(II) nitrate; (c) calcium peroxide.

2.109 Calculate the molecular (formula) mass of each compound: (a) iron(II) acetate tetrahydrate; (b) sulfur tetrachloride; (c) potassium permanganate.

2.110 Give the number of atoms of the specified element in a formula unit of each of the following compounds, and calculate the molecular (formula) mass:

(a) Oxygen in aluminum sulfate, $\text{Al}_2(\text{SO}_4)_3$
 (b) Hydrogen in ammonium hydrogen phosphate, $(\text{NH}_4)_2\text{HPO}_4$
 (c) Oxygen in the mineral azurite, $\text{Cu}_3(\text{OH})_2(\text{CO}_3)_2$

2.111 Give the number of atoms of the specified element in a formula unit of each of the following compounds, and calculate the molecular (formula) mass:

(a) Hydrogen in ammonium benzoate, $\text{C}_6\text{H}_5\text{COONH}_4$
 (b) Nitrogen in hydrazinium sulfate, $\text{N}_2\text{H}_6\text{SO}_4$
 (c) Oxygen in the mineral leadhillite, $\text{Pb}_4\text{SO}_4(\text{CO}_3)_2(\text{OH})_2$

2.112 Give the formula, name, and molecular mass of the following molecules:

2.113 Give the formula, name, and molecular mass of the following molecules:

Problems in Context

2.114 Before the use of systematic names, many compounds had common names. Give the systematic name for each of the following:

- Blue vitriol, $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$
- Slaked lime, $\text{Ca}(\text{OH})_2$
- Oil of vitriol, H_2SO_4
- Washing soda, Na_2CO_3
- Muriatic acid, HCl
- Epsom salt, $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$
- Chalk, CaCO_3
- Dry ice, CO_2
- Baking soda, NaHCO_3
- Lye, NaOH

2.115 Each circle contains a representation of a binary compound. Determine its name, formula, and molecular (formula) mass.

Comprehensive Problems

2.116 Helium is the lightest noble gas and the second most abundant element (after hydrogen) in the universe.

- The radius of a helium atom is 3.1×10^{-11} m; the radius of its nucleus is 2.5×10^{-15} m. What fraction of the spherical atomic volume is occupied by the nucleus (V of a sphere $= \frac{4}{3}\pi r^3$)?
- The mass of a helium-4 atom is 6.64648×10^{-24} g, and each of its two electrons has a mass of 9.10939×10^{-28} g. What fraction of this atom's mass is contributed by its nucleus?

2.117 Give the molecular mass of each compound depicted below, and provide a correct name for any that are named incorrectly.

2.118 Polyatomic ions are named by patterns that apply to elements in a given group. Using the periodic table and Table 2.6, give the name of each of the following: (a) SeO_4^{2-} ; (b) AsO_4^{3-} ; (c) BrO_2^- ; (d) HSeO_4^- ; (e) TeO_3^{2-} .

2.119 Ammonium dihydrogen phosphate, formed from the reaction of phosphoric acid with ammonia, is used as a crop fertilizer as well as a component of some fire extinguishers. (a) What are the mass percentages of N and P in the compound? (b) How much ammonia is incorporated into 100. g of the compound?

2.120 Nitrogen forms more oxides than any other element. The percents by mass of N in three different nitrogen oxides are (I) 46.69%, (II) 36.85%, and (III) 25.94%. For each compound, determine (a) the simplest whole-number ratio of N to O and (b) the number of grams of oxygen per 1.00 g of nitrogen.

2.121 The number of atoms in 1 dm^3 of aluminum is nearly the same as the number of atoms in 1 dm^3 of lead, but the densities of these metals are very different (see Table 1.7). Explain.

2.122 You are working in the laboratory, preparing sodium chloride. Consider the following results for three preparations of the compound:

Explain these results in terms of the laws of conservation of mass and definite composition.

2.123 Scenes A–I depict various types of matter on the atomic scale. Choose the correct scene(s) for each of the following:

- A mixture that fills its container
- A substance that cannot be broken down into simpler ones
- An element with a very high resistance to flow
- A homogeneous mixture
- An element that conforms to the walls of its container and displays an upper surface
- A gas consisting of diatomic particles
- A gas that can be broken down into simpler substances
- A substance with a 2/1 ratio of its component atoms
- Matter that can be separated into its component substances by physical means
- A heterogeneous mixture
- Matter that obeys the law of definite composition

2.124 The seven most abundant ions in seawater make up more than 99% by mass of the dissolved compounds. Here are their abundances in units of mg ion/kg seawater: chloride 18,980; sodium 10,560; sulfate 2650; magnesium 1270; calcium 400; potassium 380; hydrogen carbonate 140.

- What is the mass % of each ion in seawater?
- What percent of the total mass of ions is represented by sodium ions?
- How does the total mass % of alkaline earth metal ions compare with the total mass % of alkali metal ions?
- Which make up the larger mass fraction of dissolved components, anions or cations?

2.125 The following scenes represent a mixture of two monatomic gases undergoing a reaction when heated. Which mass law(s) is (are) illustrated by this change?

2.126 When barium (Ba) reacts with sulfur (S) to form barium sulfide (BaS), each Ba atom reacts with an S atom. If 2.50 cm^3 of Ba reacts with 1.75 cm^3 of S, are there enough Ba atoms to react with the S atoms (d of Ba = 3.51 g/cm^3 ; d of S = 2.07 g/cm^3)?

2.127 Succinic acid (*below*) is an important metabolite in biological energy production. Give the molecular formula, molecular mass, and the mass percent of each element in succinic acid.

2.128 Fluoride ion is poisonous in relatively low amounts: 0.2 g of F^- per 70 kg of body weight can cause death. Nevertheless, in order to prevent tooth decay, F^- ions are added to drinking water at a concentration of 1 mg of F^- ion per L of water. How many liters of fluoridated drinking water would a 70-kg person have to consume in one day to reach this toxic level? How many kilograms of sodium fluoride would be needed to treat an 8.50×10^7 -gal reservoir?

2.129 Antimony has many uses, for example, in infrared devices and as part of an alloy in lead storage batteries. The element has two naturally occurring isotopes, one with mass 120.904 amu and the other with mass 122.904 amu. (a) Write the ^A_ZX notation for each isotope. (b) Use the atomic mass of antimony from the periodic table to calculate the natural abundance of each isotope.

2.130 Dinitrogen monoxide (N_2O ; nitrous oxide) is a greenhouse gas that enters the atmosphere principally from natural fertilizer breakdown. Some studies have shown that the isotope ratios of ^{15}N to ^{14}N and of ^{18}O to ^{16}O in N_2O depend on the source, which can thus be determined by measuring the relative abundances of molecular masses in a sample of N_2O .

- What different molecular masses are possible for N_2O ?
- The percent abundance of ^{14}N is 99.6%, and that of ^{16}O is 99.8%. Which molecular mass of N_2O is least common, and which is most common?

2.131 Use the box color(s) in the periodic table below to identify the element(s) described by each of the following:

- Four elements that are nonmetals
- Two elements that are metals
- Three elements that are gases at room temperature
- Three elements that are solid at room temperature
- One pair of elements likely to form a covalent compound
- Another pair of elements likely to form a covalent compound
- One pair of elements likely to form an ionic compound with formula MX
- Another pair of elements likely to form an ionic compound with formula MX
- Two elements likely to form an ionic compound with formula M_2X
- Two elements likely to form an ionic compound with formula MX_2
- An element that forms no compounds
- A pair of elements whose compounds exhibit the law of multiple proportions

2.132 The two isotopes of potassium with significant abundances in nature are ^{39}K (isotopic mass = 38.9637 amu, 93.258%) and ^{41}K (isotopic mass = 40.9618 amu, 6.730%). Fluorine has only one naturally occurring isotope, ^{19}F (isotopic mass = 18.9984 amu). Calculate the formula mass of potassium fluoride.

2.133 Boron trifluoride is used as a catalyst in the synthesis of organic compounds. When this compound is analyzed by mass spectrometry, several different $1+$ ions form, including ions

representing the whole molecule as well as molecular fragments formed by the loss of one, two, and three F atoms. Given that boron has two naturally occurring isotopes, ^{10}B and ^{11}B , and fluorine has one, ^{19}F , calculate the masses of all possible 1+ ions.

2.134 Nitrogen monoxide (NO) is a bioactive molecule in blood. Low NO concentrations cause respiratory distress and the formation of blood clots. Doctors prescribe nitroglycerin, $\text{C}_3\text{H}_5\text{N}_3\text{O}_9$, and isoamyl nitrate, $(\text{CH}_3)_2\text{CHCH}_2\text{CH}_2\text{ONO}_2$, to increase the blood level of NO. If each compound releases one molecule of NO per atom of N it contains, calculate the mass percent of NO in each.

2.135 When a sample of pure carbon is analyzed by mass spectrometry, peaks X, Y, and Z are obtained. Peak Y is taller than X and Z, and Z is taller than X. What is the m/e value of the isotope responsible for peak Z?

2.136 TNT (trinitrotoluene, *below*) is used as an explosive in construction. Calculate the mass of each element in 1.00 lb of TNT.

2.137 Nuclei differ in their stability, and some are so unstable that they undergo radioactive decay. The ratio of the number of neutrons to number of protons (N/Z) in a nucleus correlates with its stability. Calculate the N/Z ratio for (a) ^{144}Sm ; (b) ^{56}Fe ; (c) ^{20}Ne ; (d) ^{107}Ag . (e) The radioactive isotope ^{238}U decays in a series of nuclear reactions that includes another uranium isotope, ^{234}U , and three lead isotopes, ^{214}Pb , ^{210}Pb , and ^{206}Pb . How many neutrons, protons, and electrons are in each of these five isotopes?

2.138 The anticancer drug Platinol (cisplatin), $\text{Pt}(\text{NH}_3)_2\text{Cl}_2$, reacts with a cancer cell's DNA and interferes with its growth. (a) What is the mass % of platinum (Pt) in Platinol? (b) If

Pt costs \$51/g, how many grams of Platinol can be made for \$1.00 million (assume that the cost of Pt determines the cost of the drug)?

2.139 From the periodic table below, give the name, symbol, atomic number, atomic mass, period number, and group number of (a) the *building-block elements* (red), which occur in nearly every biological molecule, and (b) the *macronutrients* (green), which are either essential ions in cell fluids or part of many biomolecules.

2.140 The block diagram below classifies the components of matter on the macroscopic scale. Identify blocks (a)–(d).

2.141 Which of the steps in the following process involve(s) a physical change and which involve(s) a chemical change?

Concepts and Skills to Review Before You Study This Chapter

- › atomic mass (Section 2.4)
- › names and formulas of compounds (Section 2.7)
- › molecular (or formula) mass (Section 2.7)
- › molecular and structural formulas and ball-and-stick and space-filling models (Section 2.7)

In 1964, scientists realized that a chemical extracted from the bark of the Pacific yew tree (*see photo*) showed promise as a chemotherapy drug. It took several years to determine the formula of the compound (now known as Taxol) and many more years to find a method of synthesizing it starting with simpler compounds found in the needles of the more common European yew tree. Chemists had to determine the amounts of reactants required to make the compound, and the amount of compound that the reactions would produce. Currently, Taxol is the best-selling cancer drug.

Determining the amounts of substances is important in countless other applications. Environmental chemists, for example, want to determine the amount of air pollutants a sample of coal will produce when burned, while a polymer chemist must determine the amounts of reactants needed to prepare a new plastic material. The study of the quantitative aspects of formulas and reactions is known as **stoichiometry**.

IN THIS CHAPTER . . . We relate the mass of a substance to the number of chemical entities comprising it (atoms, ions, molecules, or formula units) and apply this relationship to formulas and equations.

- › We discuss the mole, the chemist's unit for amount of a substance, and use it to convert between mass and number of entities.
- › We also use the mole concept to derive a chemical formula from the results of mass analysis.
- › We compare three types of chemical formulas.
- › We learn how to write chemical equations and how to balance them in terms of the amounts of substances reacting and produced.
- › We calculate the amounts of reactants and products in a reaction and see why one of the reactants limits the amount of product that can form and, thus, the reaction yield.

3.1 THE MOLE

In daily life, we often measure things by weighing or by counting: we weigh coffee beans or bananas, but we count eggs or pencils. And we use mass units (a kilogram of coffee beans) or counting units (a dozen pencils) to express the amount. Similarly, the daily routine in the laboratory involves measuring substances. We want to know the numbers of chemical entities—atoms, ions, molecules, or formula units—that react with each other, but how can we possibly count or weigh such minute objects? As you'll see, chemists have devised a unit, called the *mole*, to *count chemical entities by weighing a very large number of them*.

Defining the Mole

The mole (abbreviated mol) is the SI unit for amount of substance:

- A **mole** is the amount of a substance that contains the same number of entities (atoms, molecules, or other particles) as the number of atoms in

Imagine a Mole of . . .

A mole of any ordinary object is a staggering amount: a mole of periods (.) lined up side by side would equal the radius of our galaxy; a mole of marbles stacked tightly together would cover the continental United States 70 miles deep. However, atoms and molecules are not ordinary objects: you can swallow a mole of water molecules (about 18 mL) in one gulp!

16
S
32.06

1 atom of S has a mass of 32.06 amu and 1 mol (6.022×10^{23} atoms) of S has a mass of 32.06 g
 1 atom of Fe has a mass of 55.85 amu and 1 mol (6.022×10^{23} atoms) of Fe has a mass of 55.85 g

Note also that, since atomic masses are relative, 1 Fe atom weighs 55.85/32.06 as much as 1 S atom, and 1 mol of Fe weighs 55.85/32.06 as much as 1 mol of S.

- **Compounds.** The mass in *atomic mass units (amu)* of one molecule (or formula unit) of a compound is the *same numerically* as the mass in *grams (g)* of 1 mole of the compound. Thus, for example,

1 molecule of H_2O has a mass of 18.02 amu and 1 mol (6.022×10^{23} molecules) of H_2O has a mass of 18.02 g
 1 formula unit of NaCl has a mass of 58.44 amu and 1 mol (6.022×10^{23} formula units) of NaCl has a mass of 58.44 g

Figure 3.1 One mole (6.022×10^{23} entities) of some familiar substances. From left to right: 1 mol of copper (63.55 g), of liquid H_2O (18.02 g), of sodium chloride (table salt, 58.44 g), of sucrose (table sugar, 342.3 g), and of aluminum (26.98 g).

Source: Charles D. Winters/McGraw Hill

12 g of carbon-12. This number is called **Avogadro's number** (N_A) and is enormous: ◀

$$1 \text{ mole (1 mol) contains } 6.022 \times 10^{23} \text{ entities (to four significant figures)} \quad (3.1)$$

A counting unit, like *dozen*, tells you the number of objects but not their mass; a mass unit, like *kilogram*, tells you the mass of the objects but not their number. The mole tells you both—the *number* of objects in a given *mass* of substance:

1 mol of carbon-12 contains 6.022×10^{23} carbon-12 atoms *and* has a mass of 12 g

What does it mean that the mole unit allows you to count entities by weighing the sample? Suppose you have a sample of carbon-12 and want to know the number of atoms present. You find that the sample weighs 6 g, so it is 0.5 mol of carbon-12 and contains $0.5(6.022 \times 10^{23})$, or 3.011×10^{23} atoms:

6 g of carbon-12 is 0.5 mol of carbon-12 and contains 3.011×10^{23} atoms

Knowing the amount (in moles), the mass (in grams), and the number of entities becomes very important when we mix different substances to run a reaction. The central relationship between masses on the atomic scale and on the macroscopic scale is the same for elements and compounds:

- **Elements.** The mass in *atomic mass units (amu)* of one atom of an element is the *same numerically* as the mass in *grams (g)* of 1 mole of atoms of the element. Recall from Chapter 2 that each atom of an element is considered to have the *atomic mass* given in the periodic table. Thus,

Note also that, since atomic masses are relative, 1 Fe atom weighs 55.85/32.06 as much as 1 S atom, and 1 mol of Fe weighs 55.85/32.06 as much as 1 mol of S.

- **Compounds.** The mass in *atomic mass units (amu)* of one molecule (or formula unit) of a compound is the *same numerically* as the mass in *grams (g)* of 1 mole of the compound. Thus, for example,

1 molecule of H_2O has a mass of 18.02 amu and 1 mol (6.022×10^{23} molecules) of H_2O has a mass of 18.02 g
 1 formula unit of NaCl has a mass of 58.44 amu and 1 mol (6.022×10^{23} formula units) of NaCl has a mass of 58.44 g

Here, too, because masses are relative, 1 H_2O molecule weighs 18.02/58.44 as much as 1 NaCl formula unit, and 1 mol of H_2O weighs 18.02/58.44 as much as 1 mol of NaCl.

The two key points to remember about the importance of the mole unit are

- The *mole* lets us relate the *number* of entities to the *mass* of a sample of those entities.
- The mole maintains the *same numerical relationship* between mass on the atomic scale (atomic mass units, amu) and mass on the macroscopic scale (grams, g).

In everyday terms, a grocer *does not* know that there are 1 dozen eggs from their weight or that there is 1 kilogram of coffee beans from their count, because eggs and coffee beans do not have fixed masses. But, by weighing out 63.55 g (1 mol) of copper, a chemist *does* know that there are 6.022×10^{23} copper atoms, because all copper atoms have an atomic mass of 63.55 amu. Figure 3.1 shows 1 mole of some familiar elements and compounds.

Determining Molar Mass

The **molar mass** ($\mathcal{M}$) of a substance is the mass of a mole of its entities (atoms, molecules, or formula units) and has units of grams per mole (g/mol). The periodic table is indispensable for calculating molar mass:

1. *Elements.* To find the molar mass, look up the atomic mass and note whether the element is monatomic or molecular.

- *Monatomic elements.* The molar mass of a monatomic element is the periodic table value in grams per mole.* For example, the molar mass of neon is 20.18 g/mol, and the molar mass of gold is 196.97 g/mol.
- *Molecular elements.* You must know the formula of a molecular element to determine the molar mass (see Figure 2.18). For example, in air, oxygen exists most commonly as diatomic molecules, so the molar mass of O₂ is twice that of O:

$$\text{Molar mass } (\mathcal{M}) \text{ of O}_2 = 2 \times \mathcal{M} \text{ of O} = 2 \times 16.00 \text{ g/mol} = 32.00 \text{ g/mol}$$

The most common form of sulfur exists as octatomic molecules, S₈:

$$\mathcal{M} \text{ of S}_8 = 8 \times \mathcal{M} \text{ of S} = 8 \times 32.06 \text{ g/mol} = 256.5 \text{ g/mol}$$

2. *Compounds.* The molar mass of a compound is the sum of the molar masses of the atoms in the formula. Thus, from the formula of sulfur dioxide, SO₂, we know that 1 mol of SO₂ molecules contains 1 mol of S atoms and 2 mol of O atoms:

$$\mathcal{M} \text{ of SO}_2 = \mathcal{M} \text{ of S} + (2 \times \mathcal{M} \text{ of O}) = 32.06 \text{ g/mol} + (2 \times 16.00 \text{ g/mol}) = 64.06 \text{ g/mol}$$

Similarly, for ionic compounds, such as potassium sulfide (K₂S), we have

$$\mathcal{M} \text{ of K}_2\text{S} = (2 \times \mathcal{M} \text{ of K}) + \mathcal{M} \text{ of S} = (2 \times 39.10 \text{ g/mol}) + 32.06 \text{ g/mol} = 110.26 \text{ g/mol}$$

Thus, *subscripts in a formula refer to individual atoms (or ions) as well as to moles of atoms (or ions).* Table 3.1 summarizes these ideas for glucose, C₆H₁₂O₆, the essential sugar in energy metabolism.

Glucose

Table 3.1 | Information Contained in the Chemical Formula of Glucose, C₆H₁₂O₆ ($\mathcal{M}$ = 180.16 g/mol)

	Carbon (C)	Hydrogen (H)	Oxygen (O)
Atoms in one molecule of compound	6 atoms	12 atoms	6 atoms
Moles of atoms in one mole of compound	6 mol of atoms	12 mol of atoms	6 mol of atoms
Atoms in one mole of compound	$6(6.022 \times 10^{23})$ atoms	$12(6.022 \times 10^{23})$ atoms	$6(6.022 \times 10^{23})$ atoms
Mass of one molecule of compound	$6(12.01 \text{ amu}) = 72.06 \text{ amu}$	$12(1.008 \text{ amu}) = 12.10 \text{ amu}$	$6(16.00 \text{ amu}) = 96.00 \text{ amu}$
Mass of one mole of compound	72.06 g	12.10 g	96.00 g

Converting Between Amount, Mass, and Number of Chemical Entities

One of the most common skills in the lab—and on exams—is converting between amount (mol), mass (g), and number of entities of a substance.

1. *Converting between amount and mass.* If you know the amount of a substance, you can find its mass, and vice versa. The molar mass ($\mathcal{M}$), which expresses the equivalence between 1 mole of a substance and its mass in grams, is the conversion factor between amount and mass:

$$\frac{\text{no. of grams}}{1 \text{ mol}} \quad \text{or} \quad \frac{1 \text{ mol}}{\text{no. of grams}}$$

- *From amount (mol) to mass (g),* multiply by the molar mass to cancel the mole unit:

$$\text{Mass (g)} = \text{amount (mol)} \times \frac{\text{no. of grams}}{1 \text{ mol}} = n \times \mathcal{M} \quad (3.2)$$

where n = the number of moles

*The mass value in the periodic table has no units because it is a *relative* atomic mass, given by the atomic mass (in amu) divided by 1 amu ($\frac{1}{12}$ mass of one ¹²C atom in amu):

$$\text{Relative atomic mass} = \frac{\text{atomic mass (amu)}}{\frac{1}{12} \text{ mass of } ^{12}\text{C (amu)}}$$

Therefore, you use the same number (with different units) for the atomic mass and for the molar mass.

- From mass (g) to amount (mol), divide by the molar mass to cancel the mass unit:

$$\text{Amount (mol)} = \text{mass (g)} \times \frac{1 \text{ mol}}{\text{no. of grams}} = \frac{\text{mass}}{\mathcal{M}} \quad (3.3)$$

- Converting between amount and number. Similarly, if you know the amount (mol), you can find the number of entities, and vice versa. Avogadro's number, N_A , which expresses the equivalence between 1 mole of a substance and the number of entities it contains, is the conversion factor between amount and number of entities:

$$\frac{6.022 \times 10^{23} \text{ entities}}{1 \text{ mol}} \quad \text{or} \quad \frac{1 \text{ mol}}{6.022 \times 10^{23} \text{ entities}}$$

- From amount (mol) to number of entities, multiply by Avogadro's number to cancel the mole unit:

$$\text{No. of entities} = \text{amount (mol)} \times \frac{6.022 \times 10^{23} \text{ entities}}{1 \text{ mol}} = n \times N_A \quad (3.4)$$

- From number of entities to amount (mol), divide by Avogadro's number to cancel the number of entities:

$$\text{Amount (mol)} = \frac{\text{no. of entities}}{6.022 \times 10^{23} \text{ entities}} = \frac{\text{no. of entities}}{N_A} \quad (3.5)$$

Figure 3.2 Mass-mole-number relationships for elements. N_A = Avogadro's number, n = number of moles, $\mathcal{M}$ = molar mass

Amount-Mass-Number Conversions Involving Elements We begin with amount-mass-number relationships of elements. As Figure 3.2 shows, *convert mass or number of entities (atoms or molecules) to amount (mol) first*. For molecular elements, such as O_2 , Avogadro's number gives *molecules* per mole.

Let's work through several sample problems that show these conversions for some elements.

SAMPLE PROBLEM 3.1 | Converting Between Mass and Amount of an Element

Problem Silver (Ag) is used in jewelry and tableware but no longer in U.S. coins. How many grams of Ag are in 0.0342 mol of Ag?

Plan We know the amount of Ag (0.0342 mol) and have to find the mass (g). To convert units of *moles* of Ag to *grams* of Ag, we multiply by the *molar mass* of Ag, which we find in the periodic table (see the road map).

Solution Converting from amount (mol) of Ag to mass (g):

$$\text{Mass (g) of Ag} = 0.0342 \text{ mol Ag} \times \frac{107.87 \text{ g Ag}}{1 \text{ mol Ag}} = 3.69 \text{ g Ag}$$

Check We rounded the mass to three significant figures because the amount (in mol) has three. The units are correct. About $0.03 \text{ mol} \times 100 \text{ g/mol}$ gives 3 g; the small mass makes sense because 0.0342 is a small fraction of a mole.

FOLLOW-UP PROBLEMS

Brief Solutions for all Follow-up Problems appear at the end of the chapter.

3.1A Graphite is the crystalline form of carbon used in “lead” pencils. How many moles of carbon are in 315 mg of graphite? Include a road map that shows how you planned the solution.

3.1B A soda can contains about 14 g of aluminum (Al), the most abundant element in Earth's crust. How many soda cans can be made from 52 mol of Al? Include a road map that shows how you planned the solution.

SOME SIMILAR PROBLEMS 3.12(a) and 3.13(a)

Road Map

SAMPLE PROBLEM 3.2 | Converting Between Number of Entities and Amount of an Element

Problem Gallium (Ga) is a key element in solar panels, calculators, and other light-sensitive electronic devices. How many Ga atoms are in 2.85×10^{-3} mol of gallium?

Plan We know the amount of gallium (2.85×10^{-3} mol) and need the number of Ga atoms. We multiply amount (mol) by Avogadro's number to find number of atoms (see the road map).

Solution Converting from amount (mol) of Ga to number of atoms:

$$\begin{aligned}\text{No. of Ga atoms} &= 2.85 \times 10^{-3} \text{ mol Ga} \times \frac{6.022 \times 10^{23} \text{ Ga atoms}}{1 \text{ mol Ga}} \\ &= 1.72 \times 10^{21} \text{ Ga atoms}\end{aligned}$$

Check The number of atoms has three significant figures because the number of moles does. When we round amount (mol) of Ga and Avogadro's number, we have $\sim(3 \times 10^{-3} \text{ mol})(6 \times 10^{23} \text{ atoms/mol}) = 18 \times 10^{20}$, or 1.8×10^{21} atoms, so our answer seems correct.

FOLLOW-UP PROBLEMS

3.2A At rest, a person inhales 9.72×10^{21} nitrogen molecules in an average breath of air. How many moles of nitrogen *atoms* are inhaled? (*Hint:* In air, nitrogen occurs as a diatomic molecule.) Include a road map that shows how you planned the solution.

3.2B A tank contains 325 mol of compressed helium (He) gas. How many He atoms are in the tank? Include a road map that shows how you planned the solution.

SOME SIMILAR PROBLEMS 3.12(b) and 3.13(b)

Road Map

For the next sample problem, note that mass and number of entities relate directly to amount (mol), but *not* to each other. Therefore, *to convert between mass and number, first convert to amount*.

SAMPLE PROBLEM 3.3 | Converting Between Number of Entities and Mass of an Element

Problem Iron (Fe) is the main component of steel and, thus, the most important metal in industrial society; it is also essential in the human body. How many Fe atoms are in 95.8 g of Fe?

Plan We know the mass of Fe (95.8 g) and need the number of Fe atoms. We cannot convert directly from mass to number of atoms, so we first convert to amount (mol) by dividing the mass of Fe by its molar mass. Then, we multiply amount (mol) by Avogadro's number to find number of atoms (see the road map).

Solution Converting from mass (g) of Fe to amount (mol):

$$\text{Amount (mol) of Fe} = 95.8 \text{ g Fe} \times \frac{1 \text{ mol Fe}}{55.85 \text{ g Fe}} = 1.72 \text{ mol Fe}$$

Converting from amount (mol) of Fe to number of Fe atoms:

$$\begin{aligned}\text{No. of Fe atoms} &= 1.72 \text{ mol Fe} \times \frac{6.022 \times 10^{23} \text{ atoms Fe}}{1 \text{ mol Fe}} \\ &= 1.04 \times 10^{24} \text{ atoms Fe}\end{aligned}$$

Check Rounding the mass and the molar mass of Fe, we have $\sim 100 \text{ g}/(\sim 60 \text{ g/mol}) = 1.7 \text{ mol}$. Therefore, the number of atoms should be a bit less than twice Avogadro's number: $< 2(6 \times 10^{23}) = < 1.2 \times 10^{24}$, so the answer seems correct.

Comment The two steps can be combined into one:

$$\text{Amount (mol) of Fe} = 95.8 \text{ g Fe} \times \frac{1 \text{ mol Fe}}{55.85 \text{ g Fe}} \times \frac{6.022 \times 10^{23} \text{ atoms Fe}}{1 \text{ mol Fe}} = 1.04 \times 10^{24} \text{ atoms Fe}$$

Amount-Mass-Number Conversions Involving Compounds Only one new step is needed to solve amount-mass-number problems involving compounds: we need the chemical formula to find the molar mass and the amount of each element in the compound. The relationships are shown in Figure 3.3, and Sample Problem 3.4 applies them.

Figure 3.3 Amount-mass-number relationships for compounds. Use the chemical formula to find the amount (mol) of each element in a compound. N_A = Avogadro's number, n = number of moles, $\mathcal{M}$ = molar mass

Road Map

SAMPLE PROBLEM 3.4 | Converting Between Number of Entities and Mass of a Compound

Problem Ammonium carbonate is a white solid that decomposes with warming. It has many uses, for example, as a component in baking powder, fire extinguishers, and smelling salts.

- How many formula units are in 41.6 g of ammonium carbonate?
- How many O atoms are in this sample?
- How many H atoms are in this sample?

Plan (a) We know the mass of the compound (41.6 g) and need to find the number of formula units. As you just saw in Sample Problem 3.3, to convert mass to number of entities, we have to find the amount (mol). To do so, we divide the mass by the molar mass ($\mathcal{M}$), which we calculate from the compound formula (see Sample Problem 2.15). Once we have the amount (mol), we multiply by Avogadro's number to find the number of formula units (see the road map). (b) To find the number of O atoms, we multiply the number of formula units by the number of O atoms in 1 formula unit (see the road map). (c) To find the number of H atoms, we multiply the number of formula units by the number of H atoms in 1 formula unit (see the road map).

Solution (a) The formula is $(\text{NH}_4)_2\text{CO}_3$ (see Table 2.6). Calculating the molar mass:

$$\begin{aligned}\mathcal{M} &= (2 \times \mathcal{M} \text{ of N}) + (8 \times \mathcal{M} \text{ of H}) + (1 \times \mathcal{M} \text{ of C}) + (3 \times \mathcal{M} \text{ of O}) \\ &= (2 \times 14.01 \text{ g/mol N}) + (8 \times 1.008 \text{ g/mol H}) + 12.01 \text{ g/mol C} + (3 \times 16.00 \text{ g/mol O}) \\ &= 96.09 \text{ g/mol } (\text{NH}_4)_2\text{CO}_3\end{aligned}$$

Converting from mass (g) to amount (mol):

$$\begin{aligned}\text{Amount (mol) of } (\text{NH}_4)_2\text{CO}_3 &= 41.6 \text{ g } (\text{NH}_4)_2\text{CO}_3 \times \frac{1 \text{ mol } (\text{NH}_4)_2\text{CO}_3}{96.09 \text{ g } (\text{NH}_4)_2\text{CO}_3} \\ &= 0.433 \text{ mol } (\text{NH}_4)_2\text{CO}_3\end{aligned}$$

Converting from amount (mol) to formula units:

$$\begin{aligned}\text{Formula units of } (\text{NH}_4)_2\text{CO}_3 &= 0.433 \text{ mol } (\text{NH}_4)_2\text{CO}_3 \\ &\times \frac{6.022 \times 10^{23} \text{ formula units } (\text{NH}_4)_2\text{CO}_3}{1 \text{ mol } (\text{NH}_4)_2\text{CO}_3} \\ &= 2.61 \times 10^{23} \text{ formula units } (\text{NH}_4)_2\text{CO}_3\end{aligned}$$

(b) Finding the number of O atoms:

$$\begin{aligned}\text{No. of O atoms} &= 2.61 \times 10^{23} \text{ formula units } (\text{NH}_4)_2\text{CO}_3 \times \frac{3 \text{ O atoms}}{1 \text{ formula unit } (\text{NH}_4)_2\text{CO}_3} \\ &= 7.83 \times 10^{23} \text{ O atoms}\end{aligned}$$

(c) Finding the number of H atoms:

$$\begin{aligned}\text{No. of H atoms} &= 2.61 \times 10^{23} \text{ formula units } (\text{NH}_4)_2\text{CO}_3 \times \frac{8 \text{ H atoms}}{1 \text{ formula unit } (\text{NH}_4)_2\text{CO}_3} \\ &= 2.09 \times 10^{24} \text{ H atoms}\end{aligned}$$

Check In (a), the units are correct. Since the mass is less than half the molar mass ($\sim 42/96 < 0.5$), the number of formula units should be less than half Avogadro's number ($\sim 2.6 \times 10^{23} / 6.0 \times 10^{23} < 0.5$).

Comment A common mistake is to forget the subscript “2” outside the parentheses in $(\text{NH}_4)_2\text{CO}_3$, which would give a much lower molar mass and an incorrect value for the number of H atoms in the sample.

FOLLOW-UP PROBLEMS

3.4A Tetraphosphorus decoxide reacts with water to form phosphoric acid, a major industrial acid. In the laboratory, the oxide is a drying agent.

(a) What is the mass (g) of 4.65×10^{22} molecules of tetraphosphorus decoxide?

(b) How many P atoms are present in this sample? Include a road map that shows how you planned the solution.

3.4B Calcium phosphate is added to some foods, such as yogurt, to boost the calcium content and it is used as an anticaking agent.

(a) How many formula units are in 75.5 g of calcium phosphate?

(b) How many phosphate ions are present in this sample? Include a road map that shows how you planned the solution.

Student Hot Spot

Student data indicate that you may struggle with converting between mass, moles, and number of entities. Access the eBook to view an additional Learning Resource video on this topic.

The Importance of Mass Percent

For many purposes, it is important to know how much of an element is present in a given amount of compound. A biochemist may want the ionic composition of a mineral nutrient; an atmospheric chemist may be studying the carbon content of a fuel; a materials scientist may want the metalloid composition of a semiconductor. In this section, we find the composition of a compound in terms of mass percent and use it to find the mass of each element in the compound.

Determining Mass Percent from a Chemical Formula Each element contributes a fraction of a compound's mass, and that fraction multiplied by 100 gives the

element's mass percent. The formula and molar mass of a compound is used to find the mass percent of each element in the compound:

$$\text{Mass \% of element X} = \frac{\text{moles of X in formula} \times \text{molar mass of X (g/mol)}}{\text{mass (g) of 1 mol of compound}} \times 100 \quad (3.6)$$

As always, the individual mass percents add up to 100% (within rounding). In Sample Problem 3.5, we determine the mass percent of each element in a compound.

SAMPLE PROBLEM 3.5

Calculating the Mass Percent of Each Element in a Compound from the Formula

Problem The effectiveness of fertilizers depends on their nitrogen content. Ammonium nitrate is a common fertilizer. What is the mass percent of each element in ammonium nitrate?

Plan We know the relative amounts (mol) of the elements from the formula, and we have to find the mass % of each element. We multiply the amount of each element by its molar mass to find its mass. Dividing each element's mass by the mass of 1 mol of ammonium nitrate gives the mass fraction of that element, and multiplying the mass fraction by 100 gives the mass %. The calculation steps for any element (X) are shown in the road map.

Solution The formula is NH_4NO_3 (see Table 2.6). In 1 mol of NH_4NO_3 , there are 2 mol of N, 4 mol of H, and 3 mol of O.

Calculating the mass of 1 mol of NH_4NO_3 :

$$\begin{aligned} \mathcal{M} &= (2 \times \mathcal{M} \text{ of N}) + (4 \times \mathcal{M} \text{ of H}) + (3 \times \mathcal{M} \text{ of O}) \\ &= (2 \times 14.01 \text{ g/mol N}) + (4 \times 1.008 \text{ g/mol H}) + (3 \times 16.00 \text{ g/mol O}) \\ &= 80.05 \text{ g/mol NH}_4\text{NO}_3 \end{aligned}$$

Converting amount (mol) of N to mass (g): We have 2 mol of N in 1 mol of NH_4NO_3 , so

$$\text{Mass (g) of N} = 2 \text{ mol N} \times \frac{14.01 \text{ g N}}{1 \text{ mol N}} = 28.02 \text{ g N}$$

Finding the mass fraction of N in NH_4NO_3 :

$$\text{Mass fraction of N} = \frac{\text{total mass of N}}{\text{mass of 1 mol NH}_4\text{NO}_3} = \frac{28.02 \text{ g N}}{80.05 \text{ g NH}_4\text{NO}_3} = 0.3500$$

Changing to mass %:

$$\begin{aligned} \text{Mass \% of N} &= \text{mass fraction of N} \times 100 = 0.3500 \times 100 \\ &= 35.00 \text{ mass \% N} \end{aligned}$$

Combining the steps for each of the other elements in NH_4NO_3 :

$$\begin{aligned} \text{Mass \% of H} &= \frac{\text{mol H} \times \mathcal{M} \text{ of H}}{\text{mass of 1 mol NH}_4\text{NO}_3} \times 100 = \frac{4 \text{ mol H} \times \frac{1.008 \text{ g H}}{1 \text{ mol H}}}{80.05 \text{ g NH}_4\text{NO}_3} \times 100 \\ &= 5.037 \text{ mass \% H} \end{aligned}$$

$$\begin{aligned} \text{Mass \% of O} &= \frac{\text{mol O} \times \mathcal{M} \text{ of O}}{\text{mass of 1 mol NH}_4\text{NO}_3} \times 100 = \frac{3 \text{ mol O} \times \frac{16.00 \text{ g O}}{1 \text{ mol O}}}{80.05 \text{ g NH}_4\text{NO}_3} \times 100 \\ &= 59.96 \text{ mass \% O} \end{aligned}$$

Road Map

Check The answers make sense. The mass % of O is greater than that of N because there are more moles of O in the compound and the molar mass of O is greater. The mass % of H is small because its molar mass is small. The sum of the mass percents is 100.00%.

Comment From here on, you should be able to determine the molar mass of a compound, so that its calculation will no longer be shown.

FOLLOW-UP PROBLEMS

3.5A In mammals, lactose (milk sugar) is metabolized to glucose ($\text{C}_6\text{H}_{12}\text{O}_6$), the key nutrient for generating chemical potential energy. Calculate the mass percent of C in glucose.

3.5B For many years, compounds known as *chlorofluorocarbons* were used as refrigerants, until it was discovered that the chlorine atoms in these compounds destroy ozone molecules in the atmosphere. The compound CCl_3F is a chlorofluorocarbon with a high chlorine content. Calculate the mass percent of Cl in CCl_3F .

SOME SIMILAR PROBLEMS 3.20–3.23

Determining the Mass of an Element from Its Mass Fraction Sample Problem 3.5 shows that *an element always constitutes the same fraction of the mass of a given compound* (see Equation 3.6). We can use that fraction to find the mass of an element in any mass of a compound:

$$\text{Mass of element} = \text{mass of compound} \times \frac{\text{mass of element in 1 mol of compound}}{\text{mass of 1 mol of compound}} \quad (3.7)$$

For example, to find the mass of oxygen in 15.5 g of nitrogen dioxide, we have

$$\begin{aligned} \text{Mass (g) of O} &= 15.5 \text{ g NO}_2 \times \frac{2 \text{ mol} \times \mathcal{M} \text{ of O (g/mol)}}{\text{mass (g) of 1 mol NO}_2} \\ &= 15.5 \text{ g } \cancel{\text{NO}_2} \times \frac{32.00 \text{ g O}}{46.01 \text{ g } \cancel{\text{NO}_2}} = 10.8 \text{ g O} \end{aligned}$$

SAMPLE PROBLEM 3.6

Calculating the Mass of an Element in a Compound

Problem Use the information in Sample Problem 3.5 to determine the mass (g) of nitrogen in 650. g of ammonium nitrate.

Plan To find the mass of N in the sample of ammonium nitrate, we multiply the mass of the sample by the mass of 2 mol of N divided by the mass of 1 mol of ammonium nitrate.

Solution Finding the mass of N in a given mass of ammonium nitrate:

$$\begin{aligned} \text{Mass (g) of N} &= \text{mass (g) of NH}_4\text{NO}_3 \times \frac{2 \text{ mol N} \times \mathcal{M} \text{ of N (g/mol)}}{\text{mass (g) of 1 mol NH}_4\text{NO}_3} \\ &= 650. \text{ g } \cancel{\text{NH}_4\text{NO}_3} \times \frac{28.02 \text{ g N}}{80.05 \text{ g } \cancel{\text{NH}_4\text{NO}_3}} = 228 \text{ g N} \end{aligned}$$

Check Rounding shows that the answer is “in the right ballpark”: N accounts for about one-third of the mass of NH_4NO_3 and $\frac{1}{3}$ of 700 g is 233 g.

FOLLOW-UP PROBLEMS

3.6A Use the information in Follow-up Problem 3.5A to find the mass (g) of C in 16.55 g of glucose.

3.6B Use the information in Follow-up Problem 3.5B to find the mass (g) of Cl in 2.35 kg of CCl_3F .

SOME SIMILAR PROBLEMS 3.27 and 3.28

Road Map

Summary of Section 3.1

- › A mole of substance is the amount that contains Avogadro's number (6.022×10^{23}) of chemical entities (atoms, ions, molecules, or formula units).
- › The mass (in grams) of a mole of a given entity (atom, ion, molecule, or formula unit) has the same numerical value as the mass (in amu) of the entity. Thus, the mole allows us to count entities by weighing them.
- › Using the molar mass ($\mathcal{M}$, g/mol) of an element (or compound) and Avogadro's number as conversion factors, we can convert between amount (mol), mass (g), and number of entities.
- › The mass fraction of element X in a compound is used to find the mass of X in a given amount of the compound.

3.2 DETERMINING THE FORMULA OF AN UNKNOWN COMPOUND

In Sample Problems 3.5 and 3.6, we used a compound's formula to find the mass percent (or mass fraction) of each element in it *and* the mass of each element in any size sample of it. In this section, we do the reverse: we use the masses of elements in a compound to find the formula. Then, we look briefly at the relationship between molecular formula and molecular structure.

Let's compare three common types of formulas (Table 3.2):

- The **empirical formula** shows the *lowest* whole number of moles, and thus the *relative* number of atoms, of each element in the compound. For example, each of the compounds in Table 3.2 contains 1 C atom for every 2 H atoms and every 1 O atom (a 1/2/1 C/H/O ratio), so the empirical formula of each compound is CH_2O . As you can see from Table 3.2, different compounds can have the *same* empirical formula.
- The **molecular formula** shows the *actual* number of atoms of each element in a molecule. Table 3.2 shows that the molecular formula of formaldehyde is the same

Table 3.2 | Types of Chemical Formulas

Name	Empirical Formula	Whole-Number Multiple	$\mathcal{M}$ (g/mol)	Molecular Formula	Structural Formula
Formaldehyde	CH_2O	1	30.026	CH_2O	 Formaldehyde
Acetic acid	CH_2O	2	60.052	$\text{C}_2\text{H}_4\text{O}_2$	 Acetic acid
Glucose	CH_2O	6	180.156	$\text{C}_6\text{H}_{12}\text{O}_6$	 Glucose
Fructose	CH_2O	6	180.156	$\text{C}_6\text{H}_{12}\text{O}_6$	 Fructose

as its empirical formula: one molecule of this compound actually contains one C atom, two H atoms, and one O atom. However, the molecular formulas of acetic acid, glucose, and fructose are different from the empirical formula, but exhibit the same 1/2/1 C/H/O atom ratio as in the empirical formula.

- The **structural formula** shows the relative *placement and connections of atoms* in the molecule.

If you look closely at glucose and fructose in Table 3.2, you can see that compounds can share the same empirical and molecular formulas, but their atoms can bond in different arrangements to give different structural formulas. **Isomers** are compounds with the same molecular formula, and thus molar mass, but different physical and chemical properties. We'll discuss isomerism fully later in the text.

Now let's see how to determine empirical and molecular formulas.

Empirical Formulas

A chemist studying an unknown compound goes through a three-step process to find the empirical formula:

1. Determine the mass (g) of each component element.
2. Convert each mass (g) to amount (mol), and write a preliminary formula.
3. Convert the amounts (mol) mathematically to whole-number (integer) subscripts. To accomplish this math conversion,
 - Divide each subscript by the smallest subscript, and,
 - If necessary, multiply through by the *smallest integer* that turns all subscripts into integers.

Sample Problem 3.7 demonstrates these steps.

SAMPLE PROBLEM 3.7 | Determining an Empirical Formula from Masses of Elements

Problem A sample of an unknown compound contains 5.08 g of zinc, 1.60 g of phosphorus, and 3.32 g of oxygen. What is the empirical formula?

Plan We must find the empirical formula of this compound, $\text{Zn}_x\text{P}_y\text{O}_z$, where the subscripts “x,” “y,” and “z” represent the moles of each element in 1 mole of compound. We are given the masses of each element in a sample of the compound. We first divide each mass by the element's molar mass to find the amount (mol). Then, we construct a preliminary formula and convert the amounts (mol) to integer subscripts.

Solution Finding amount (mol) of each element:

$$\text{Amount (mol) of Zn} = 5.08 \text{ g Zn} \times \frac{1 \text{ mol Zn}}{65.38 \text{ g Zn}} = 0.0777 \text{ mol Zn}$$

$$\text{Amount (mol) of P} = 1.60 \text{ g P} \times \frac{1 \text{ mol P}}{30.97 \text{ g P}} = 0.0517 \text{ mol P}$$

$$\text{Amount (mol) of O} = 3.32 \text{ g O} \times \frac{1 \text{ mol O}}{16.00 \text{ g O}} = 0.208 \text{ mol O}$$

Using these fractions to write a preliminary formula: $\text{Zn}_{0.0777}\text{P}_{0.0517}\text{O}_{0.208}$

Converting to integer subscripts by dividing each subscript by the smallest subscript:

Since we have not yet obtained integer subscripts, multiply through by the *smallest integer* that turns all subscripts into integers. We multiply by 2 because that makes 1.5 (the subscript for Zn) into an integer:

Check The ratio of subscripts, 3/2/8, is the same as the ratio of moles, 0.0777/0.0517/0.208.

Comment Notice that the “1.5” subscript for Zn could *not* be rounded to “2.0” to obtain an integer. A more conventional way to write this formula is $\text{Zn}_3(\text{PO}_4)_2$; this compound is zinc phosphate, formerly used widely as a dental cement.

Road Map

FOLLOW-UP PROBLEMS

3.7A A sample of an unknown compound is found to contain 1.23 g of H, 12.64 g of P, and 26.12 g of O. What are the empirical formula and the name of the compound?

3.7B An unknown metal M reacts with sulfur to form a compound with the formula M_2S_3 . If 3.12 g of M reacts with 2.88 g of S, what are the names of M and M_2S_3 ? [Hint: Determine the amount (mol) of S, and use the formula to find the amount (mol) of M.]

SOME SIMILAR PROBLEMS 3.42(b), 3.43(b), 3.46, and 3.47

Molecular Formulas

If we know the molar mass of a compound, we can use the empirical formula to obtain the molecular formula, which uses as subscripts the *actual* numbers of moles of each element in 1 mol of compound. We saw that the molecular formula of formaldehyde is the same as its empirical formula (Table 3.2), but the molecular formulas of the other compounds listed in Table 3.2 are *whole-number multiples* of the empirical formula. Dividing the molar mass of these compounds by the empirical formula mass gives the whole-number multiple. For example, for glucose:

$$\text{Whole-number multiple} = \frac{\text{compound molar mass (g/mol)}}{\text{empirical formula mass (g/mol)}} = \frac{180.156 \text{ g/mol}}{30.026 \text{ g/mol}} = 6.000 = 6$$

Since the molar mass of glucose is six times as large as the empirical formula mass, the molecular formula has six times the number of atoms as the empirical formula. Multiplying the empirical formula subscripts by 6 gives the molecular formula:

Instead of giving compositional data as masses of each element, analytical laboratories provide mass percents. We use this kind of data as follows:

1. Assume 100.0 g of compound to express each mass percent directly as a mass (g).
2. Convert each mass (g) to amount (mol).
3. Derive the empirical formula.
4. Divide the molar mass of the compound by the empirical formula mass to find the whole-number multiple and the molecular formula.

SAMPLE PROBLEM 3.8

Determining a Molecular Formula from Elemental Analysis and Molar Mass

Problem During excessive physical activity, lactic acid ($\mathcal{M} = 90.08 \text{ g/mol}$) forms in muscle tissue and is responsible for muscle soreness. Elemental analysis shows that this compound has 40.0 mass % C, 6.71 mass % H, and 53.3 mass % O.

- (a) Determine the empirical formula of lactic acid.
 (b) Determine the molecular formula.

(a) Determining the empirical formula

Plan We know the mass % of each element and must convert each to an integer subscript. The mass of the sample of lactic acid is not given, but the mass percents are the same for any sample of it. Therefore, we assume there is 100.0 g of lactic acid and express each mass % as a number of grams. Then, we construct the empirical formula as in Sample Problem 3.7.

Solution Expressing mass % as mass (g) by assuming 100.0 g of lactic acid:

$$\text{Mass (g) of C} = \frac{40.0 \text{ parts C by mass}}{100 \text{ parts by mass}} \times 100.0 \text{ g} = 40.0 \text{ g C}$$

Similarly, we have 6.71 g of H and 53.3 g of O.

Converting from mass (g) of each element to amount (mol):

$$\text{Amount (mol) of C} = \text{mass of C} \times \frac{1}{\mathcal{M} \text{ of C}} = 40.0 \text{ g C} \times \frac{1 \text{ mol C}}{12.01 \text{ g C}} = 3.33 \text{ mol C}$$

Chromacome/Stockbyte/
Getty Images

Similarly, we have 6.66 mol of H and 3.33 mol of O.

Constructing the preliminary formula: $\text{C}_{3.33}\text{H}_{6.66}\text{O}_{3.33}$

Converting to integer subscripts by dividing each subscript by the smallest subscript:

Check The numbers of moles seem correct: the masses of C and O are each slightly more than 3 times their molar masses (e.g., for C, $40 \text{ g}/(12 \text{ g/mol}) > 3 \text{ mol}$), and the mass of H is over 6 times its molar mass of 1.

(b) Determining the molecular formula

Plan The molecular formula subscripts are whole-number multiples of the empirical formula subscripts. To find this multiple, we divide the molar mass given in the problem (90.08 g/mol) by the empirical formula mass, which we find from the sum of the elements' molar masses. Then we multiply each subscript in the empirical formula by the multiple.

Solution The empirical formula mass of CH_2O is 30.03 g/mol. Finding the whole-number multiple:

$$\text{Whole-number multiple} = \frac{\mathcal{M} \text{ of lactic acid}}{\mathcal{M} \text{ of empirical formula}} = \frac{90.08 \text{ g/mol}}{30.03 \text{ g/mol}} = 3.000 = 3$$

Determining the molecular formula:

Check The calculated molecular formula has the same ratio of moles of elements (3/6/3) as the empirical formula (1/2/1) and corresponds to the given molar mass:

$$\begin{aligned} \mathcal{M} \text{ of lactic acid} &= (3 \times \mathcal{M} \text{ of C}) + (6 \times \mathcal{M} \text{ of H}) + (3 \times \mathcal{M} \text{ of O}) \\ &= (3 \times 12.01 \text{ g/mol}) + (6 \times 1.008 \text{ g/mol}) + (3 \times 16.00 \text{ g/mol}) \\ &= 90.08 \text{ g/mol} \end{aligned}$$

FOLLOW-UP PROBLEMS

3.8A One of the most widespread environmental carcinogens (cancer-causing agents) is benzo[a]pyrene ($\mathcal{M} = 252.30 \text{ g/mol}$). It is found in coal dust, cigarette smoke, and even charcoal-grilled meat. Analysis of this hydrocarbon shows 95.21 mass % C and 4.79 mass % H. What is the molecular formula of benzo[a]pyrene?

3.8B Caffeine ($\mathcal{M} = 194.2 \text{ g/mol}$) is a stimulant found in coffee, tea, many soft drinks, and chocolate. Elemental analysis of caffeine shows 49.47 mass % C, 5.19 mass % H, 28.86 mass % N, and 16.48 mass % O. What is the molecular formula of caffeine?

SOME SIMILAR PROBLEMS 3.44, 3.45, and 3.51

Student Hot Spot

Student data indicate that you may struggle with determining a molecular formula from elemental analysis. Access the eBook to view an additional Learning Resource video on this topic.

Combustion Analysis of Organic Compounds Still another type of compositional data is obtained through **combustion analysis**, a method commonly used to measure the amounts of carbon and hydrogen in a combustible organic compound. The unknown compound is burned in an excess of pure O_2 ; during the combustion, the compound's carbon and hydrogen react with the oxygen to form CO_2 and H_2O , respectively, which are absorbed in separate containers (Figure 3.4). By weighing the absorbers

Figure 3.4 Combustion apparatus for determining formulas of organic compounds. A sample of an organic compound is burned in a stream of O_2 . The resulting H_2O is absorbed by $\text{Mg}(\text{ClO}_4)_2$, and the CO_2 is absorbed by NaOH on asbestos.

before and after combustion, we find the masses of CO_2 and H_2O produced and use them to find the masses of C and H in the compound; from these results, we find the empirical formula. Many organic compounds also contain oxygen, nitrogen, or a halogen. As long as the third element doesn't interfere with the absorption of H_2O and CO_2 , we calculate its mass by subtracting the masses of C and H from the original mass of the compound.

SAMPLE PROBLEM 3.9

Determining a Molecular Formula from Combustion Analysis

Problem Vitamin C ($\mathcal{M} = 176.12 \text{ g/mol}$) is a compound of C, H, and O found in many natural sources, especially citrus fruits. When a 1.000-g sample of vitamin C is burned in a combustion apparatus, the following data are obtained:

Mass of CO_2 absorber after combustion = 85.35 g
 Mass of CO_2 absorber before combustion = 83.85 g
 Mass of H_2O absorber after combustion = 37.96 g
 Mass of H_2O absorber before combustion = 37.55 g

What is the molecular formula of vitamin C?

Plan We find the masses of CO_2 and H_2O by subtracting the mass of each absorber before the combustion from its mass after combustion. From the mass of CO_2 , we use Equation 3.7 to find the mass of C. Similarly, we find the mass of H from the mass of H_2O . The mass of vitamin C (1.000 g) minus the sum of the masses of C and H gives the mass of O, the third element present. Then, we proceed as in Sample Problem 3.8: calculate the amount (mol) of each element using its molar mass, construct the empirical formula, determine the whole-number multiple from the given molar mass, and construct the molecular formula.

Solution Finding the masses of combustion products:

Mass (g) of CO_2 = mass of CO_2 absorber after – mass before
 = 85.35 g – 83.85 g = 1.50 g CO_2
 Mass (g) of H_2O = mass of H_2O absorber after – mass before
 = 37.96 g – 37.55 g = 0.41 g H_2O

Calculating masses (g) of C and H using Equation 3.7:

Mass of element = mass of compound $\times \frac{\text{mass of element in 1 mol of compound}}{\text{mass of 1 mol of compound}}$

$$\begin{aligned}\text{Mass (g) of C} &= \text{mass of } \text{CO}_2 \times \frac{1 \text{ mol C} \times \mathcal{M} \text{ of C}}{\text{mass of 1 mol } \text{CO}_2} = 1.50 \text{ g } \text{CO}_2 \times \frac{12.01 \text{ g C}}{44.01 \text{ g } \text{CO}_2} \\ &= 0.409 \text{ g C}\end{aligned}$$

$$\begin{aligned}\text{Mass (g) of H} &= \text{mass of } \text{H}_2\text{O} \times \frac{2 \text{ mol H} \times \mathcal{M} \text{ of H}}{\text{mass of 1 mol } \text{H}_2\text{O}} = 0.41 \text{ g } \text{H}_2\text{O} \times \frac{2.016 \text{ g H}}{18.02 \text{ g } \text{H}_2\text{O}} \\ &= 0.046 \text{ g H}\end{aligned}$$

Calculating mass (g) of O:

$$\begin{aligned}\text{Mass (g) of O} &= \text{mass of vitamin C sample} - (\text{mass of C} + \text{mass of H}) \\ &= 1.000 \text{ g} - (0.409 \text{ g} + 0.046 \text{ g}) = 0.545 \text{ g O}\end{aligned}$$

Finding the amounts (mol) of elements: Dividing the mass (g) of each element by its molar mass gives 0.0341 mol of C, 0.046 mol of H, and 0.0341 mol of O.

Constructing the preliminary formula: $\text{C}_{0.0341}\text{H}_{0.046}\text{O}_{0.0341}$

Determining the empirical formula: Dividing through by the smallest subscript gives

$$\frac{\text{C}_{0.0341}}{0.0341} \frac{\text{H}_{0.046}}{0.0341} \frac{\text{O}_{0.0341}}{0.0341} = \text{C}_{1.00} \text{H}_{1.3} \text{O}_{1.00}$$

We find that 3 is the smallest integer that makes all subscripts into integers:

$$\text{C}_{(1.00 \times 3)} \text{H}_{(1.3 \times 3)} \text{O}_{(1.00 \times 3)} = \text{C}_{3.00} \text{H}_{3.9} \text{O}_{3.00} \approx \text{C}_3 \text{H}_4 \text{O}_3$$

Determining the molecular formula:

$$\text{Whole-number multiple} = \frac{\mathcal{M} \text{ of vitamin C}}{\mathcal{M} \text{ of empirical formula}} = \frac{176.12 \text{ g/mol}}{88.06 \text{ g/mol}} = 2.000 = 2$$

Check The element masses seem correct: carbon makes up slightly more than 0.25 of the mass of CO_2 ($12 \text{ g}/44 \text{ g} > 0.25$), as do the masses in the problem ($0.409 \text{ g}/1.50 \text{ g} > 0.25$). Hydrogen makes up slightly more than 0.10 of the mass of H_2O ($2 \text{ g}/18 \text{ g} > 0.10$), as do the masses in the problem ($0.046 \text{ g}/0.41 \text{ g} > 0.10$). The molecular formula has the same ratio of subscripts ($6/8/6$) as the empirical formula ($3/4/3$) and the preliminary formula ($0.0341/0.046/0.0341$), and it gives the known molar mass:

$$(6 \times \mathcal{M} \text{ of C}) + (8 \times \mathcal{M} \text{ of H}) + (6 \times \mathcal{M} \text{ of O}) = \mathcal{M} \text{ of vitamin C}$$

$$(6 \times 12.01 \text{ g/mol}) + (8 \times 1.008 \text{ g/mol}) + (6 \times 16.00 \text{ g/mol}) = 176.12 \text{ g/mol}$$

Comment The subscript we calculated for H was 3.9, which we rounded to 4. But, if we had strung the calculation steps together, we would have obtained 4.0:

$$\text{Subscript of H} = 0.41 \text{ g H}_2\text{O} \times \frac{2.016 \text{ g H}}{18.02 \text{ g H}_2\text{O}} \times \frac{1 \text{ mol H}}{1.008 \text{ g H}} \times \frac{1}{0.0341 \text{ mol H}} \times 3 = 4.0$$

FOLLOW-UP PROBLEMS

3.9A A dry-cleaning solvent ($\mathcal{M} = 146.99 \text{ g/mol}$) that contains C, H, and Cl is suspected to be a cancer-causing agent. When a 0.250-g sample was studied by combustion analysis, 0.451 g of CO_2 and 0.0617 g of H_2O were formed. Find the molecular formula.

3.9B Anabolic steroids are sometimes used illegally by athletes to increase muscle strength. A forensic chemist analyzes some tablets suspected of being a popular steroid and determines that the substance in the tablets contains only C, H, and O and has a molar mass of 300.42 g/mol. When a 1.200-g sample is studied by combustion analysis, 3.516 g of CO_2 and 1.007 g of H_2O are collected. What is the molecular formula of the substance in the tablets?

SOME SIMILAR PROBLEMS 3.48 and 3.49

Summary of Section 3.2

- From the masses of elements in a compound, their relative numbers of moles are found, which gives the empirical formula.
- If the molar mass of the compound is known, the molecular formula, the actual numbers of moles of each element, can also be determined, because the molecular formula is a whole-number multiple of the empirical formula.
- Atoms can bond in different arrangements (structural formulas). Two or more compounds with the same molecular formula are isomers.
- Combustion analysis provides data on the masses of carbon and hydrogen in an organic compound, which are used to obtain the formula.

3.3

WRITING AND BALANCING CHEMICAL EQUATIONS

Thinking in terms of amounts, rather than masses, allows us to view reactions as interactions among large populations of particles rather than as involving grams of material. For example, for the formation of HF from H_2 and F_2 , if we weigh the substances, we find that

Macroscopic level (grams): 2.016 g of H_2 and 38.00 g of F_2 react to form 40.02 g of HF

This information tells us little except that mass is conserved. However, if we convert these masses (g) to amounts (mol), we find that

Macroscopic level (moles): 1 mol of H_2 and 1 mol of F_2 react to form 2 mol of HF

This information reveals that 6.022×10^{23} H_2 molecules react with 6.022×10^{23} F_2 molecules to form $2(6.022 \times 10^{23}) = 1.204 \times 10^{24}$ HF molecules. Dividing by Avogadro's number gives the reaction between individual molecules:

Molecular level: 1 molecule of H_2 and 1 molecule of F_2 react to form 2 molecules of HF

Thus, the *macroscopic (molar) change corresponds to the submicroscopic (molecular) change* (Figure 3.5). This information forms the essence of a **chemical equation**, a statement that uses formulas to express the identities and quantities of substances involved in a chemical or physical change.

Steps for Balancing an Equation To present a chemical change quantitatively, an equation must be *balanced*: the same number of each type of atom must appear on both sides. As an example, here is a description of a chemical change that occurs in many fireworks and in a common lecture demonstration: a magnesium strip burns in oxygen gas to yield powdery magnesium oxide. (Light and heat are also produced, but we are concerned here only with substances.) Converting this description into a balanced equation involves the following steps:

1. *Translating the statement.* We first translate the chemical statement into a “skeleton” equation: the substances present *before* the change, called **reactants**, are placed to the left of a yield arrow, which points to the substances produced *during* the change, called **products**:

At the beginning of the balancing process, we put a blank in front of each formula to remind us that we have to account for its atoms.

2. *Balancing the atoms.* By shifting our attention back and forth, we *match the numbers of each type of atom on the left and the right of the yield arrow*. In each blank, we place a **balancing (stoichiometric) coefficient**, a numerical multiplier of *all the atoms* in the formula that follows it. In general, balancing is easiest when we

- Start with the most complex substance, the one with the largest number of different types of atoms.
- End with the least complex substance, such as an element by itself.

In this case, MgO is the most complex, so we place a coefficient 1 in that blank:

To balance the Mg in MgO , we place a 1 in front of Mg on the left:

Figure 3.5 The formation of HF on the macroscopic and molecular levels and written as a balanced chemical equation.

The O atom in MgO must be balanced by one O atom on the left. One-half an O₂ molecule provides one O atom:

In terms of numbers of each type of atom, the equation is balanced.

3. *Adjusting the coefficients.* There are several conventions about the final coefficients:

- In most cases, *the smallest whole-number coefficients are preferred.* In this case, one-half of an O₂ molecule cannot exist, so we multiply the equation by 2:

- We used the coefficient 1 to remind us to balance each substance. But, a coefficient of 1 is implied by the presence of the formula, so we don't write it:

(This convention is similar to not writing a subscript “1” in a formula.)

4. *Checking.* After balancing and adjusting the coefficients, we always check that the equation is balanced:

5. *Specifying the states of matter.* The final equation also indicates the physical state of each substance or whether it is dissolved in water (aqueous solution). The abbreviations used for these states are shown. From the original statement, we know that the Mg “strip” is solid, O₂ is a gas, and “powdery” MgO is also solid. The balanced equation, therefore, is

As you saw in Figure 3.5, *balancing coefficients refer to both individual chemical entities and moles of entities.* Thus,

2 atoms of Mg and 1 molecule of O₂ yield 2 formula units of MgO

2 moles of Mg and 1 mole of O₂ yield 2 moles of MgO

Figure 3.6 depicts this reaction on three levels:

- *Macroscopic level (photos)*, as it appears in the laboratory
- *Atomic level (blow-up circles)*, as chemists imagine it (with darker colored atoms representing the stoichiometry)
- *Symbolic level*, in the form of the balanced chemical equation

Keep in mind several key points about the balancing process:

- A coefficient operates on *all* the atoms in the formula that follows it:

2MgO means 2 × (MgO), or 2 Mg atoms + 2 O atoms

2Ca(NO₃)₂ means 2 × [Ca(NO₃)₂], or 2 Ca atoms + 4 N atoms + 12 O atoms

- Chemical formulas *cannot* be altered. Thus, in step 2 of the example, we *cannot* balance the O atoms by changing MgO to MgO₂ because MgO₂ is a different compound.
- Other reactants or products *cannot* be added. Thus, we *cannot* balance the O atoms by changing the reactant from O₂ molecules to O atoms or by adding an O atom to the products. The description of the reaction mentions oxygen gas, which consists of O₂ molecules, *not* separate O atoms.
- A balanced equation remains balanced if we multiply all the coefficients by the same number. For example,

<i>g</i>	for gas
<i>l</i>	for liquid
<i>s</i>	for solid
<i>aq</i>	for aqueous solution

Figure 3.6 A three-level view of the reaction between magnesium and oxygen.

Source: (all): Charles D. Winters/McGraw Hill

is also balanced because the coefficients have all been multiplied by 2. However, *by convention*, we balance an equation with the *smallest* whole-number coefficients.

- While atoms must be conserved in a chemical equation, each side of the equation may *not* have the same number of molecules or moles. In the reaction between magnesium and oxygen, 3 moles of reactants (Mg and O_2) produce only 2 moles of product (MgO).

SAMPLE PROBLEM 3.10

Balancing a Chemical Equation

Problem Within the cylinders of a car's engine, the hydrocarbon octane (C_8H_{18}), one of many components of gasoline, mixes with oxygen from the air and burns to form carbon dioxide and water vapor. Write a balanced equation for this reaction.

Solution

1. Translate the statement into a skeleton equation (with coefficient blanks). Octane and oxygen are reactants; “oxygen from the air” implies molecular oxygen, O_2 . Carbon dioxide and water vapor are products:

2. Balance the atoms. Start with the most complex substance, C_8H_{18} , and balance O_2 last:

The C atoms in C_8H_{18} end up in CO_2 . Each CO_2 contains 1 C atom, so 8 molecules of CO_2 are needed to balance the 8 C atoms in each C_8H_{18} :

The H atoms in C_8H_{18} end up in H_2O . The 18 H atoms in C_8H_{18} require the coefficient 9 in front of H_2O :

There are 25 atoms of O on the right (16 in 8CO_2 plus 9 in $9\text{H}_2\text{O}$), so we place the coefficient $\frac{25}{2}$ in front of O_2 :

3. *Adjust the coefficients.* Multiply through by 2 to obtain whole numbers:

4. *Check* that the equation is balanced:

5. *Specify* states of matter. C_8H_{18} is liquid; O_2 , CO_2 , and H_2O vapor are gases:

Comment This is an example of a combustion reaction. Any compound containing C and H that burns in an excess of air produces CO_2 and H_2O .

FOLLOW-UP PROBLEMS

3.10A Write a balanced equation for each of the following:

- (a) A characteristic reaction of Group 1 elements: chunks of sodium react violently with water to form hydrogen gas and sodium hydroxide solution.
- (b) The destruction of marble statuary by acid rain: aqueous nitric acid reacts with calcium carbonate to form carbon dioxide, water, and aqueous calcium nitrate.
- (c) Halogen compounds exchanging bonding partners: phosphorus trifluoride is prepared by the reaction of phosphorus trichloride and hydrogen fluoride; hydrogen chloride is the other product. The reaction involves gases only.

3.10B Write a balanced equation for each of the following:

- (a) Explosive decomposition of dynamite: liquid nitroglycerine ($\text{C}_3\text{H}_5\text{N}_3\text{O}_9$) explodes to produce a mixture of gases—carbon dioxide, water vapor, nitrogen, and oxygen.
- (b) A reaction that takes place in a self-contained breathing apparatus: solid potassium superoxide (KO_2) reacts with carbon dioxide gas to produce oxygen gas and solid potassium carbonate.
- (c) The production of iron from its ore in a blast furnace: solid iron(III) oxide reacts with carbon monoxide gas to produce solid iron metal and carbon dioxide gas.

SOME SIMILAR PROBLEMS 3.58–3.63

Visualizing a Reaction with a Molecular Scene A great way to focus on the rearrangement of atoms from reactants to products is by visualizing an equation as a molecular scene. Here's a representation of the combustion of octane we just balanced in Sample Problem 3.10:

Now let's work through a sample problem to do the reverse—derive a balanced equation from a molecular scene.

SAMPLE PROBLEM 3.11

Writing a Balanced Equation from a Molecular Scene

Problem The following molecular scenes depict an important reaction in nitrogen chemistry (nitrogen is *blue*; oxygen is *red*):

Write a balanced equation for this reaction.

Plan To write a balanced equation, we first have to determine the formulas of the molecules and obtain coefficients by counting the number of each type of molecule. Then, we arrange this information in the correct equation format, using the smallest whole-number coefficients and including states of matter.

Solution The reactant circle shows only one type of molecule. It has two N and five O atoms, so the formula is N_2O_5 ; there are four of these molecules. The product circle shows two different types of molecules, one type with one N and two O atoms, and the other with two O atoms; there are eight NO_2 and two O_2 . Thus, we have

Writing the balanced equation with the smallest whole-number coefficients and all substances as gases:

Check Reactant (4 N, 10 O) $\longrightarrow$ products (4 N, 8 + 2 = 10 O)

- › Balancing coefficients are integer multipliers for *all* the atoms in a formula and apply to the individual entities or to moles of entities.

3.4 CALCULATING QUANTITIES OF REACTANT AND PRODUCT

A balanced equation is essential for all calculations involving chemical change: *if you know the number of moles of one substance, the balanced equation tells you the numbers of moles of the others.*

Stoichiometrically Equivalent Molar Ratios from the Balanced Equation

In a balanced equation, *the amounts (mol) of substances are stoichiometrically equivalent to each other*, which means that a specific amount of one substance is formed from, produces, or reacts with a specific amount of the other. The quantitative relationships are expressed as *stoichiometrically equivalent molar ratios* that we use as conversion factors to calculate the amounts. For example, consider the equation for the combustion of propane, a hydrocarbon fuel used in cooking and water heating:

If we view the reaction quantitatively in terms of C_3H_8 , we see that

Therefore, in this reaction,

We chose to look at C_3H_8 , but any two of the substances are stoichiometrically equivalent to each other. Thus,

and so on. A balanced equation contains a wealth of quantitative information relating individual chemical entities, amounts (mol) of substances, and masses of substances, and Table 3.3 presents the quantitative information contained in the equation for the combustion of propane.

Here's a typical problem that shows how stoichiometric equivalence is used to create conversion factors: in the combustion of propane, how many moles of O_2 are consumed when 10.0 mol of H_2O is produced? To solve this problem, we have to find the molar ratio between O_2 and H_2O . From the balanced equation, we see that, for every 5 mol of O_2 consumed, 4 mol of H_2O is formed:

As with any equivalent quantities, we can construct two conversion factors, depending on the quantity we want to find:

$$\frac{5 \text{ mol } \text{O}_2}{4 \text{ mol } \text{H}_2\text{O}} \quad \text{or} \quad \frac{4 \text{ mol } \text{H}_2\text{O}}{5 \text{ mol } \text{O}_2}$$

Table 3.3 | Information Contained in a Balanced Equation

Viewed in Terms Of	Reactants		→	Products	
	$\text{C}_3\text{H}_8(\text{g})$	+ $5\text{O}_2(\text{g})$	→	$3\text{CO}_2(\text{g})$	+ $4\text{H}_2\text{O}(\text{g})$
Molecules	1 molecule C_3H_8 + 5 molecules O_2		→	3 molecules CO_2 + 4 molecules H_2O	
			→		
Amount (mol)	1 mol C_3H_8 + 5 mol O_2		→	3 mol CO_2 + 4 mol H_2O	
Mass (amu)	44.09 amu C_3H_8 + 160.00 amu O_2		→	132.03 amu CO_2 + 72.06 amu H_2O	
Mass (g)	44.09 g C_3H_8 + 160.00 g O_2		→	132.03 g CO_2 + 72.06 g H_2O	
Total mass (g)	204.09 g		→	204.09 g	

Since we want to find the amount (mol) of O_2 and we know the amount (mol) of H_2O , we choose “5 mol O_2 /4 mol H_2O ” to cancel “mol H_2O ”:

$$\text{Amount (mol) of } \text{O}_2 \text{ consumed} = 10.0 \cancel{\text{mol H}_2\text{O}} \times \frac{5 \text{ mol } \text{O}_2}{4 \cancel{\text{mol H}_2\text{O}}} = 12.5 \text{ mol } \text{O}_2$$

$\text{mol H}_2\text{O}$ $\xrightarrow[\text{molar ratio as conversion factor}]{}$ mol O_2

Be sure to note that the 5/4 ratio between O_2 and H_2O is a *molar* ratio and not a *mass* ratio:

$$5 \text{ mol } \text{O}_2 = 4 \text{ mol } \text{H}_2\text{O} \quad \text{but} \quad 5 \text{ g } \text{O}_2 \neq 4 \text{ g } \text{H}_2\text{O}$$

You cannot solve this type of problem without the balanced equation. Here is an approach for solving *any* stoichiometry problem that involves a reaction:

1. Write the balanced equation.
2. When necessary, convert the known mass (or number of entities) of one substance to amount (mol) using its molar mass (or Avogadro's number).
3. Use the molar ratio in the balanced equation to calculate the unknown amount (mol) of the other substance.
4. When necessary, convert the amount of that other substance to the desired mass (or number of entities) using its molar mass (or Avogadro's number).

Figure 3.7 summarizes the possible relationships among quantities of substances in a reaction, and Sample Problems 3.12 and 3.13 apply three of them in the first chemical step of converting copper ore to copper metal.

SAMPLE PROBLEM 3.12 | Calculating Quantities of Reactants and Products: Amount (mol) to Amount (mol) and to Mass (g)

Problem In a lifetime, the average American uses more than a half ton (> 500 kg) of copper in coins, plumbing, and wiring. Copper is obtained from sulfide ores, such as chalcocite [copper(I) sulfide] by a multistep process. After initial grinding, the ore is “roasted” (heated strongly with oxygen gas) to form powdered copper(I) oxide and gaseous sulfur dioxide.

(a) How many moles of oxygen are required to roast 10.0 mol of copper(I) sulfide?

(b) How many grams of sulfur dioxide form when 10.0 mol of copper(I) sulfide reacts?

Plan We *always* write the balanced equation first. The formulas of the reactants are Cu_2S and O_2 , and the formulas of the products are Cu_2O and SO_2 , so we have

Source: Stephen Frisch/McGraw Hill

(a) We know the amount of Cu_2S (10.0 mol) and must find the amount (mol) of O_2 that is needed to roast it. The balanced equation shows that 3 mol of O_2 is needed to roast 2 mol of Cu_2S , so the conversion factor for finding amount (mol) of O_2 is 3 mol O_2 /2 mol Cu_2S (see the road map).

(b) Starting with the given amount of the reactant (10.0 mol of Cu_2S), we need to find the mass (g) of product (SO_2) that forms. We find the amount (mol) of SO_2 using the molar ratio (2 mol SO_2 /2 mol Cu_2S) and then multiply by its molar mass (64.06 g/mol) to find the mass (g) of SO_2 (see the road map).

Solution (a) Calculating the amount of O_2 :

$$\text{Amount (mol) of } \text{O}_2 = 10.0 \text{ mol } \text{Cu}_2\text{S} \times \frac{3 \text{ mol } \text{O}_2}{2 \text{ mol } \text{Cu}_2\text{S}} = 15.0 \text{ mol } \text{O}_2$$

(b) Combining the two conversion steps into one calculation, we have

$$\text{Mass (g) of } \text{SO}_2 = 10.0 \text{ mol } \text{Cu}_2\text{S} \times \frac{2 \text{ mol } \text{SO}_2}{2 \text{ mol } \text{Cu}_2\text{S}} \times \frac{64.06 \text{ g } \text{SO}_2}{1 \text{ mol } \text{SO}_2} = 641 \text{ g } \text{SO}_2$$

Check (a) The units are correct, and the answer is reasonable because this molar ratio of O_2 to Cu_2S (15/10) is identical to the ratio in the balanced equation (3/2).

(b) The answer makes sense, since the molar ratio shows that 10.0 mol of SO_2 is formed and each mole weighs about 64 g. We rounded to three significant figures.

Comment A common mistake is to invert the conversion factor; for part (a), that calculation would be

$$\text{Amount (mol) of } \text{O}_2 = 10.0 \text{ mol } \text{Cu}_2\text{S} \times \frac{2 \text{ mol } \text{Cu}_2\text{S}}{3 \text{ mol } \text{O}_2} = \frac{6.67 \text{ mol}^2 \text{ Cu}_2\text{S}}{1 \text{ mol } \text{O}_2}$$

The strange units should alert you that an error was made in setting up the conversion factor. Also note that this answer, 6.67, is *less* than 10.0, whereas the equation shows that there should be *more* moles of O_2 (3 mol) than moles of Cu_2S (2 mol). Be sure to think through the calculation when setting up the conversion factor and canceling units.

FOLLOW-UP PROBLEMS

3.12A Thermite is a mixture of iron(III) oxide and aluminum powders that was once used to weld railroad tracks. It undergoes a spectacular reaction to yield solid aluminum oxide and molten iron. How many moles of iron(III) oxide are needed to form 3.60×10^3 mol of iron? Include a road map that shows how you planned the solution.

3.12B The tarnish that forms on objects made of silver is solid silver sulfide; it can be removed by reacting it with aluminum metal to produce silver metal and solid aluminum sulfide. How many moles of silver are produced when 32.6 g of silver sulfide reacts? Include a road map that shows how you planned the solution.

Road Map

Figure 3.7 Summary of amount-mass-number relationships in a chemical equation. Start at any box (known) and move to any other (unknown) by using the conversion factor on the arrow. As always, convert to amount (mol) first. N_A = Avogadro's number, n = number of moles, M = molar mass

Road Map

Limiting “Reactants” in Everyday Life

Limiting-“reactant” situations arise in business all the time. A car assembly-plant manager must order more tires if there are 1500 car bodies and only 4000 tires, and a clothes manufacturer must cut more sleeves if there are 320 sleeves for 170 shirt bodies. You’ve probably faced such situations in daily life as well. A muffin recipe calls for 2 cups of flour and 1 cup of sugar, but you have 3 cups of flour and only $\frac{3}{4}$ cup of sugar. Clearly, the flour is in excess and the sugar limits the number of muffins you can make. Or, you’re in charge of making cheeseburgers for a picnic, and you have 10 buns, 12 meat patties, and 15 slices of cheese. Here, the number of buns limits how many cheeseburgers you can make. Or, there are 26 students and only 23 microscopes in a cell biology lab. You’ll find that limiting-“reactant” situations are almost limitless.

SAMPLE PROBLEM 3.13

Calculating Quantities of Reactants and Products: Mass to Mass

Problem During the roasting of chalcocite (see Sample Problem 3.12), how many kilograms of oxygen are required to form 2.86 kg of copper(I) oxide?

Plan In this problem, we know the mass of the product, Cu_2O (2.86 kg), and we need the mass (kg) of O_2 that reacts to form it. Therefore, we must convert from mass of product to amount of product to amount of reactant to mass of reactant. We convert the mass of Cu_2O from kg to g and then to amount (mol). Then, we use the molar ratio (3 mol O_2 /2 mol Cu_2O) to find the amount (mol) of O_2 required. Finally, we convert the amount of O_2 to g and then kg (see the road map).

Solution Converting from kilograms of Cu_2O to moles of Cu_2O : combining the mass unit conversion with the mass-to-amount conversion gives

$$\text{Amount (mol) of Cu}_2\text{O} = 2.86 \text{ kg Cu}_2\text{O} \times \frac{10^3 \text{ g}}{1 \text{ kg}} \times \frac{1 \text{ mol Cu}_2\text{O}}{143.10 \text{ g Cu}_2\text{O}} = 20.0 \text{ mol Cu}_2\text{O}$$

Converting from moles of Cu_2O to moles of O_2 :

$$\text{Amount (mol) of O}_2 = 20.0 \text{ mol Cu}_2\text{O} \times \frac{3 \text{ mol O}_2}{2 \text{ mol Cu}_2\text{O}} = 30.0 \text{ mol O}_2$$

Converting from moles of O_2 to kilograms of O_2 : combining the amount-to-mass conversion with the mass unit conversion gives

$$\text{Mass (kg) of O}_2 = 30.0 \text{ mol O}_2 \times \frac{32.00 \text{ g O}_2}{1 \text{ mol O}_2} \times \frac{1 \text{ kg}}{10^3 \text{ g}} = 0.960 \text{ kg O}_2$$

Check The units are correct. Rounding to check the math, for example, in the final step, $\sim 30 \text{ mol} \times 30 \text{ g/mol} \times 1 \text{ kg}/10^3 \text{ g} = 0.90 \text{ kg}$. The answer seems reasonable: even though the amount (mol) of O_2 is greater than the amount (mol) of Cu_2O , the mass of O_2 is less than the mass of Cu_2O because M of O_2 is less than M of Cu_2O .

Comment Sample Problems 3.12 and 3.13 highlight the main point for solving stoichiometry problems: *convert the information given into amount (mol)*. Then, use the appropriate molar ratio and any other conversion factors to complete the solution.

SOME SIMILAR PROBLEMS 3.71(b), 3.72(b), and 3.73–3.76

Reactions That Involve a Limiting Reactant

In problems up to now, the amount of *one* reactant was given, and we assumed there was enough of the other reactants to react with it completely. For example, using the chemical reaction for the roasting of copper ore (see Sample Problem 3.12), suppose we want the amount (mol) of SO_2 that forms when 5.2 mol of Cu_2S reacts with O_2 :

We assume the 5.2 mol of Cu_2S reacts with as much O_2 as needed. Because all the Cu_2S reacts, its initial amount of 5.2 mol determines, or *limits*, the amount of SO_2 that can form, no matter how much more O_2 is present. In this situation, we call Cu_2S the **limiting reactant** (or *limiting reagent*).

Suppose, however, we know the amounts of both Cu_2S and O_2 and need to find out how much SO_2 forms. We first have to determine whether Cu_2S or O_2 is the limiting reactant—that is, which one is completely used up—because that reactant limits how much SO_2 can form. The reactant that is *not* limiting is present *in excess*, which means the amount that doesn’t react is left over. ◀

To determine which is the limiting reactant, we use the molar ratios in the balanced equation to perform a series of calculations to see *which reactant forms less product*.

Determining the Limiting Reactant Let's clarify these ideas in a much more appetizing situation. Suppose you have a job making ice cream sundaes. Each sundae requires two scoops (12 oz) of ice cream, one cherry, and 50 mL of syrup:

A mob of 25 ravenous school kids enters, and each one wants a sundae with vanilla ice cream and chocolate syrup. You have 300 oz of vanilla ice cream (at 6 oz per scoop), 30 cherries, and 1 L of syrup: can you feed them all? A series of calculations based on the balanced equation shows the number of sundaes you can make from each ingredient:

$$\text{Ice cream: No. of sundaes} = 300 \cancel{\text{ oz ice cream}} \times \frac{1 \cancel{\text{ scoop}}}{6 \cancel{\text{ oz ice cream}}} \times \frac{1 \text{ sundae}}{2 \cancel{\text{ scoops}}} = 25 \text{ sundaes}$$

$$\text{Cherries: No. of sundaes} = 30 \cancel{\text{ cherries}} \times \frac{1 \text{ sundae}}{1 \cancel{\text{ cherry}}} = 30 \text{ sundaes}$$

$$\text{Syrup: No. of sundaes} = 1000 \cancel{\text{ mL syrup}} \times \frac{1 \text{ sundae}}{50 \cancel{\text{ mL syrup}}} = 20 \text{ sundaes}$$

Of the reactants (ice cream, cherry, syrup), the syrup forms the *least* amount of product (sundaes), so it is the limiting “reactant.” When all the syrup has been used up, some ice cream and cherries are “unreacted,” so they are in excess:

300 oz (50 scoops) + 30 cherries + 1 L syrup $\longrightarrow$

20 sundaes + 60 oz (10 scoops) + 10 cherries

Figure 3.8 shows a similar example with different initial (starting) quantities.

Using Reaction Tables in Limiting-Reactant Problems A good way to keep track of the quantities in a limiting-reactant problem is with a *reaction table*. The balanced equation appears at the top for the column heads. The table shows the

- *Initial* quantities of reactants and products *before* the reaction
- *Change* in the quantities of reactants and products *during* the reaction
- *Final* quantities of reactants and products remaining *after* the reaction

The “reactants” (ice cream, cherry, and syrup) form the “product” (sundae).

A 12 oz (2 scoops) ice cream + 1 cherry + 50 mL syrup $\longrightarrow$ 1 sundae

B 4 sundaes can be made with the ice cream + 6 sundaes can be made with the cherries + 2 sundaes can be made with the syrup $\longrightarrow$ 2 sundaes + in excess (4 scoops ice cream, 4 cherries)

Only two sundaes can be made before all the syrup is used up, so syrup is the limiting “reactant”; four scoops of ice cream and four cherries are “in excess.”

Figure 3.8 An ice cream sundae analogy for limiting reactants.

For example, for the ice cream sundae “reaction,” the reaction table would be

Quantity	12 oz (2 scoops)	+	1 cherry	+	50 mL syrup	→	1 sundae
Initial	300 oz (50 scoops)		30 cherries		1000 mL syrup		0 sundaes
Change	−240 oz (40 scoops)		−20 cherries		−1000 mL syrup		+20 sundaes
Final	60 oz (10 scoops)		10 cherries		0 mL syrup		20 sundaes

The body of the table shows the following important points:

- In the **Initial** line, “product” has not yet formed, so the entry is “0 sundaes.”
- In the **Change** line, since the reactants (ice cream, cherries, and syrup) are used during the reaction, their quantities decrease, so the changes in their quantities have a *negative* sign. At the same time, the quantity of product (sundaes) increases, so the change in its quantity has a *positive* sign. The numbers in the Change line must reflect the molar ratio in the reaction. For example, there is a 2 scoop/1 sundae “molar” ratio, so, if 20 sundaes are produced, 40 scoops of ice cream are used.
- For the **Final** line, we *add* the Change and Initial lines. Notice that some reactants (ice cream and cherries) are in excess, whereas the limiting reactant (syrup) is used up.

Solving Limiting-Reactant Problems In limiting-reactant problems, *the amounts of two (or more) reactants are given, and we first determine which is limiting*. To do this, just as we did with the ice cream sundaes, we use the balanced equation to solve a series of calculations to see how much product forms from the given amount of each reactant: the limiting reactant is the one that yields the *least* amount of product.

The following problems examine these ideas from several aspects. In Sample Problem 3.14, we solve the problem by looking at a molecular scene; in Sample Problem 3.15, we start with the amounts (mol) of two reactants; and, in Sample Problem 3.16, we start with masses of two reactants.

SAMPLE PROBLEM 3.14 | Using Molecular Depictions in a Limiting-Reactant Problem

Problem Nuclear engineers use chlorine trifluoride to prepare uranium fuel for power plants. The compound is formed as a gas by the reaction of elemental chlorine and fluorine. The circle shows a representative portion of the reaction mixture before the reaction starts (chlorine is *dark green*; fluorine is *light green*).

- Find the limiting reactant.
- Write a reaction table for the process.
- Draw a representative portion of the mixture after the reaction is complete. (*Hint:* The ClF_3 molecule has Cl bonded to three individual F atoms.)

Plan (a) We have to find the limiting reactant. The first step is to write the balanced equation, so we need the formulas and states of matter. From the name, chlorine trifluoride, we know the product consists of one Cl atom bonded to three F atoms, or ClF_3 . Elemental chlorine and fluorine are the diatomic molecules Cl_2 and F_2 , and all three substances are gases. To find the limiting reactant, we find the number of molecules of product that would form from the numbers of molecules of each reactant: whichever forms less product is the limiting reactant. (b) We use these numbers of molecules to write a reaction table. (c) We use the numbers in the Final line of the table to draw the scene.

Solution (a) The balanced equation is

$$\begin{aligned} \text{For } \text{Cl}_2: \text{Molecules of } \text{ClF}_3 &= 3 \text{ molecules of } \text{Cl}_2 \times \frac{2 \text{ molecules of } \text{ClF}_3}{1 \text{ molecule of } \text{Cl}_2} \\ &= 6 \text{ molecules of } \text{ClF}_3 \end{aligned}$$

$$\begin{aligned} \text{For } \text{F}_2: \text{Molecules of } \text{ClF}_3 &= 6 \text{ molecules of } \text{F}_2 \times \frac{2 \text{ molecules of } \text{ClF}_3}{3 \text{ molecules of } \text{F}_2} \\ &= 4 \text{ molecules of } \text{ClF}_3 \end{aligned}$$

Because it forms less product, F_2 is the limiting reactant.

(b) Since F_2 is the limiting reactant, all of it (6 molecules) is used in the Change line of the reaction table. To find the value for Cl_2 in the Change line, we must calculate the number of Cl_2 molecules that react with 6 molecules of F_2 :

$$\text{Molecules of } Cl_2 \text{ that react} = 6 \text{ molecules of } F_2 \times \frac{1 \text{ molecule of } Cl_2}{3 \text{ molecules of } F_2} = 2 \text{ molecules of } Cl_2$$

Putting the values in the reaction table gives

Molecules	$Cl_2(g)$	+	$3F_2(g)$	→	$2ClF_3(g)$
Initial	3		6		0
Change	−2		−6		+4
Final	1		0		4

(c) The representative portion of the final reaction mixture includes 1 molecule of Cl_2 (the reactant in excess) and 4 molecules of product ClF_3 .

Check The equation is balanced: reactants (2 Cl, 6 F) → products (2 Cl, 6 F). And, as shown in the circles, the numbers of each type of atom before and after the reaction are equal. Let's think through our choice of limiting reactant. From the equation, one Cl_2 needs three F_2 to form two ClF_3 . Therefore, the three Cl_2 molecules in the circle depicting reactants need nine (3×3) F_2 . But there are only six F_2 , so there is not enough F_2 to react with the available Cl_2 ; or put the other way, there is too much Cl_2 to react with the available F_2 . From either point of view, F_2 is the limiting reactant.

Comment Notice that there are fewer Cl_2 molecules than F_2 molecules initially. The limiting reactant is *not* the reactant present in the smaller amount, but the reactant that forms *less product*.

FOLLOW-UP PROBLEMS

3.14A B_2 (B is red) reacts with AB as shown below:

Write a balanced equation for the reaction, and determine the limiting reactant.

3.14B Sulfur dioxide gas reacts with oxygen gas to produce sulfur trioxide, as shown below (sulfur is yellow; oxygen is red):

Write a balanced equation for the reaction, and determine the limiting reactant.

SOME SIMILAR PROBLEMS 3.79 and 3.80

SAMPLE PROBLEM 3.15

Calculating Quantities in a Limiting-Reactant Problem: Amount to Amount

Problem In another preparation of ClF_3 (see Sample Problem 3.14), 0.750 mol of Cl_2 reacts with 3.00 mol of F_2 . (a) Find the limiting reactant. (b) Write a reaction table.

Plan (a) We find the limiting reactant by calculating the amount (mol) of ClF_3 formed from the amount (mol) of each reactant: the reactant that forms fewer moles of ClF_3 is limiting.

(b) We enter those values into the reaction table.

Solution (a) Determining the limiting reactant:

Finding amount (mol) of ClF_3 from amount (mol) of Cl_2 :

$$\text{Amount (mol) of } \text{ClF}_3 = 0.750 \text{ mol } \text{Cl}_2 \times \frac{2 \text{ mol } \text{ClF}_3}{1 \text{ mol } \text{Cl}_2} = 1.50 \text{ mol } \text{ClF}_3$$

Finding amount (mol) of ClF_3 from amount (mol) of F_2 :

$$\text{Amount (mol) of } \text{ClF}_3 = 3.00 \text{ mol } \text{F}_2 \times \frac{2 \text{ mol } \text{ClF}_3}{3 \text{ mol } \text{F}_2} = 2.00 \text{ mol } \text{ClF}_3$$

In this case, Cl_2 is limiting because it forms fewer moles of ClF_3 .

(b) Writing the reaction table, with Cl_2 limiting—to find the value for F_2 in the Change line, we must calculate the amount of F_2 that reacts with 0.750 mol of Cl_2 :

$$\text{Amount (mol) of } \text{F}_2 \text{ that reacts} = 0.750 \text{ mol } \text{Cl}_2 \times \frac{3 \text{ mol of } \text{F}_2}{1 \text{ mol of } \text{Cl}_2} = 2.25 \text{ mol } \text{F}_2$$

Putting the values in the reaction table gives

Amount (mol)	$\text{Cl}_2(\text{g})$	+	$3\text{F}_2(\text{g})$	→	$2\text{ClF}_3(\text{g})$
Initial	0.750		3.00		0
Change	−0.750		−2.25		+1.50
Final	0		0.75		1.50

Check Let's check that Cl_2 is the limiting reactant by assuming, for the moment, that F_2 is limiting. If that were true, all 3.00 mol of F_2 would react to form 2.00 mol of ClF_3 . However, based on the balanced equation, obtaining 2.00 mol of ClF_3 would require 1.00 mol of Cl_2 , and only 0.750 mol of Cl_2 is present. Thus, Cl_2 must be the limiting reactant.

Comment A major point to note from Sample Problems 3.14 and 3.15 is that the relative amounts of reactants *do not* determine which is limiting, but rather the amount of product formed, which is based on the *molar ratio in the balanced equation*. In both problems, there is more F_2 than Cl_2 . However,

- Sample Problem 3.14 has an F_2/Cl_2 ratio of 6/3, or 2/1, which is less than the required molar ratio of 3/1, so F_2 is limiting and Cl_2 is in excess.
- Sample Problem 3.15 has an F_2/Cl_2 ratio of 3.00/0.750, which is greater than the required molar ratio of 3/1, so Cl_2 is limiting and F_2 is in excess.

FOLLOW-UP PROBLEMS

3.15A In the reaction in Follow-up Problem 3.14A, how many moles of product form from 1.5 mol of each reactant?

3.15B In the reaction in Follow-up Problem 3.14B, 4.2 mol of SO_2 reacts with 3.6 mol of O_2 . How many moles of SO_3 are produced?

SOME SIMILAR PROBLEMS 3.81 and 3.82

SAMPLE PROBLEM 3.16

Calculating Quantities in a Limiting-Reactant Problem: Mass to Mass

Problem A fuel mixture used in the early days of rocketry consisted of two liquids, hydrazine (N_2H_4) and dinitrogen tetroxide (N_2O_4), which ignite on contact to form nitrogen gas and water vapor.

- How many grams of nitrogen gas form when 100. g of N_2H_4 and 125 g of N_2O_4 are mixed?
- How many grams of the excess reactant remain unreacted when the reaction is over?
- Write a reaction table for this process.

Plan The amounts of two reactants are given, which means this is a limiting-reactant problem. (a) To determine the mass of product formed, we must find the limiting

reactant by calculating which of the given masses of reactant forms *less* nitrogen gas. As always, we first write the balanced equation. We convert the grams of each reactant to moles using that reactant's molar mass and then use the molar ratio from the balanced equation to find the number of moles of N_2 each reactant forms. Next, we convert the lower amount of N_2 to mass (see the road map). **(b)** To determine the mass of the excess reactant, we use the molar ratio to calculate the mass of excess reactant that is required to react with the given amount of the limiting reactant. We subtract that mass from the given amount of excess reactant; this difference is the mass of unreacted excess reactant. **(c)** We use the values based on the limiting reactant for the reaction table.

Solution (a) Writing the balanced equation:

Finding the amount (mol) of N_2 from the amount (mol) of each reactant:

$$\text{For } \text{N}_2\text{H}_4: \text{Amount (mol) of } \text{N}_2\text{H}_4 = 100. \text{ g } \text{N}_2\text{H}_4 \times \frac{1 \text{ mol } \text{N}_2\text{H}_4}{32.05 \text{ g } \text{N}_2\text{H}_4} = 3.12 \text{ mol } \text{N}_2\text{H}_4$$

$$\text{Amount (mol) of } \text{N}_2 = 3.12 \text{ mol } \text{N}_2\text{H}_4 \times \frac{3 \text{ mol } \text{N}_2}{2 \text{ mol } \text{N}_2\text{H}_4} = 4.68 \text{ mol } \text{N}_2$$

$$\text{For } \text{N}_2\text{O}_4: \text{Amount (mol) of } \text{N}_2\text{O}_4 = 125 \text{ g } \text{N}_2\text{O}_4 \times \frac{1 \text{ mol } \text{N}_2\text{O}_4}{92.02 \text{ g } \text{N}_2\text{O}_4} = 1.36 \text{ mol } \text{N}_2\text{O}_4$$

$$\text{Amount (mol) of } \text{N}_2 = 1.36 \text{ mol } \text{N}_2\text{O}_4 \times \frac{3 \text{ mol } \text{N}_2}{1 \text{ mol } \text{N}_2\text{O}_4} = 4.08 \text{ mol } \text{N}_2$$

Thus, N_2O_4 is the limiting reactant because it yields less N_2 .

Converting from amount (mol) of N_2 to mass (g):

$$\text{Mass (g) of } \text{N}_2 = 4.08 \text{ mol } \text{N}_2 \times \frac{28.02 \text{ g } \text{N}_2}{1 \text{ mol } \text{N}_2} = 114 \text{ g } \text{N}_2$$

(b) Finding the mass (g) of N_2H_4 that reacts with 125 g of N_2O_4 :

$$\begin{aligned} \text{Mass (g) of } \text{N}_2\text{H}_4 &= 125 \text{ g } \text{N}_2\text{O}_4 \times \frac{1 \text{ mol } \text{N}_2\text{O}_4}{92.02 \text{ g } \text{N}_2\text{O}_4} \times \frac{2 \text{ mol } \text{N}_2\text{H}_4}{1 \text{ mol } \text{N}_2\text{O}_4} \times \frac{32.05 \text{ g } \text{N}_2\text{H}_4}{1 \text{ mol } \text{N}_2\text{H}_4} \\ &= 87.1 \text{ g } \text{N}_2\text{H}_4 \end{aligned}$$

$$\begin{aligned} \text{Mass (g) of } \text{N}_2\text{H}_4 \text{ in excess} &= \text{initial mass of } \text{N}_2\text{H}_4 - \text{mass of } \text{N}_2\text{H}_4 \text{ reacted} \\ &= 100. \text{ g } \text{N}_2\text{H}_4 - 87.1 \text{ g } \text{N}_2\text{H}_4 = 13 \text{ g } \text{N}_2\text{H}_4 \end{aligned}$$

(c) With N_2O_4 as the limiting reactant, the reaction table is

Amount (mol)	$2\text{N}_2\text{H}_4(l)$	$+\text{N}_2\text{O}_4(l)$	$\longrightarrow$	$3\text{N}_2(g)$	$+4\text{H}_2\text{O}(g)$
Initial	3.12	1.36		0	0
Change	-2.72	-1.36		+4.08	+5.43
Final	0.40	0		4.08	5.43

Check There are more grams of N_2O_4 than N_2H_4 , but there are fewer moles of N_2O_4 because its $\mathcal{M}$ is much higher. Rounding for N_2O_4 : $120 \text{ g } \text{N}_2\text{O}_4 \times 1 \text{ mol}/90 \text{ g} \approx 1.3 \text{ mol}$; $\sim 1.3 \text{ mol} \times 3 \approx 4 \text{ mol } \text{N}_2$; $\sim 4 \text{ mol} \times 30 \text{ g/mol} \approx 120 \text{ g } \text{N}_2$.

Comment 1. Recall this *common mistake* in solving limiting-reactant problems: the limiting reactant is not the *reactant* present in fewer moles (or grams). Rather, it is the reactant that forms fewer moles (or grams) of *product*.

2. An *alternative approach* to finding the limiting reactant compares “How much is needed?” with “How much is given?” That is, based on the balanced equation,

- Find the amount (mol) of each reactant needed to react with the other reactant.
- Compare that *needed* amount with the *given* amount in the problem statement. There will be *more* than enough of one reactant (excess) and *less* than enough of the other (limiting).

Road Map (a)

Road Map (b)

For example, the balanced equation for this problem shows that 2 mol of N_2H_4 reacts with 1 mol of N_2O_4 . The amount (mol) of N_2O_4 needed to react with the given 3.12 mol of N_2H_4 is

$$\text{Amount (mol) of } \text{N}_2\text{O}_4 \text{ needed} = 3.12 \text{ mol } \text{N}_2\text{H}_4 \times \frac{1 \text{ mol } \text{N}_2\text{O}_4}{2 \text{ mol } \text{N}_2\text{H}_4} = 1.56 \text{ mol } \text{N}_2\text{O}_4$$

The amount of N_2H_4 needed to react with the given 1.36 mol of N_2O_4 is

$$\text{Amount (mol) of } \text{N}_2\text{H}_4 \text{ needed} = 1.36 \text{ mol } \text{N}_2\text{O}_4 \times \frac{2 \text{ mol } \text{N}_2\text{H}_4}{1 \text{ mol } \text{N}_2\text{O}_4} = 2.72 \text{ mol } \text{N}_2\text{H}_4$$

We are given 1.36 mol of N_2O_4 , which is *less* than the 1.56 mol of N_2O_4 needed, and we are given 3.12 mol of N_2H_4 , which is *more* than the 2.72 mol of N_2H_4 needed. Therefore, N_2O_4 is limiting, and N_2H_4 is in excess.

FOLLOW-UP PROBLEMS

Student Hot Spot

Student data indicate that you may struggle with limiting-reactant calculations. Access the eBook to view an additional Learning Resource video on this topic.

Figure 3.9 provides an overview of all of the stoichiometric relationships we've discussed in this chapter.

Theoretical, Actual, and Percent Reaction Yields

Up until now, we've assumed that 100% of the limiting reactant becomes product, that ideal methods exist for isolating the product, and that we have perfect lab technique and collect all the product. In theory, this may happen, but in reality it doesn't, and chemists recognize three types of reaction yield:

Figure 3.9 An overview of amount-mass-number stoichiometric relationships. N_A = Avogadro's number, n = number of moles, $\mathcal{M}$ = molar mass

1. **Theoretical yield.** The amount of product calculated from the molar ratio in the balanced equation is the **theoretical yield**. But, there are several reasons that the theoretical yield is *never* obtained:

- Reactant mixtures often proceed through **side reactions** that form different products (Figure 3.10). In the rocket fuel reaction in Sample Problem 3.16, for example, the reactants might form some NO in the following side reaction:

This reaction decreases the amounts of reactants available for N_2 production.

- Even more important, many reactions seem to stop before they are complete, so some limiting reactant is unused. (We'll see why in Chapter 4.)
 - Physical losses occur in every step of a separation: some solid clings to filter paper, some gaseous product escapes from the reaction vessel, and so forth. With careful technique, you can minimize, but never eliminate, such losses.
2. **Actual yield.** Given these reasons for obtaining less than the theoretical yield, the amount of product *actually* obtained is the **actual yield**. The actual yield can only be found by carrying out the reaction and measuring the mass of product actually obtained. Theoretical and actual yields are expressed in units of amount (moles) or mass (grams).
3. **Percent yield.** The **percent yield (% yield)** is the actual yield expressed as a percentage of the theoretical yield:

$$\% \text{ yield} = \frac{\text{actual yield}}{\text{theoretical yield}} \times 100 \quad (3.8)$$

By definition, the actual yield is less than the theoretical yield, so the percent yield is *always* less than 100%.

Figure 3.10 The effect of a side reaction on the yield of the main product.

SAMPLE PROBLEM 3.17 | Calculating Percent Yield

Problem Silicon carbide (SiC) is an important ceramic material made by reacting sand (silicon dioxide, SiO_2) with powdered carbon at a high temperature. Carbon monoxide is also formed. When 100.0 kg of sand is processed, 51.4 kg of SiC is recovered. What is the percent yield of SiC from this process?

Plan We are given the actual yield of SiC (51.4 kg), so we need the theoretical yield to calculate the percent yield. After writing the balanced equation, we convert the given mass of SiO_2 (100.0 kg) to amount (mol). We use the molar ratio to find the amount of SiC formed and convert it to mass (kg) to obtain the theoretical yield. Then, we use Equation 3.8 to find the percent yield (see the road map).

Solution Writing the balanced equation:

Converting from mass (kg) of SiO_2 to amount (mol):

$$\text{Amount (mol) of SiO}_2 = 100.0 \text{ kg SiO}_2 \times \frac{1000 \text{ g}}{1 \text{ kg}} \times \frac{1 \text{ mol SiO}_2}{60.08 \text{ g SiO}_2} = 1664 \text{ mol SiO}_2$$

Converting from amount (mol) of SiO_2 to amount (mol) of SiC: the molar ratio is 1 mol SiC/1 mol SiO_2 , so

$$\text{Amount (mol) of SiO}_2 = \text{moles of SiC} = 1664 \text{ mol SiC}$$

Converting from amount (mol) of SiC to mass (kg):

$$\text{Mass (kg) of SiC} = 1664 \text{ mol SiC} \times \frac{40.09 \text{ g SiC}}{1 \text{ mol SiC}} \times \frac{1 \text{ kg}}{1000 \text{ g}} = 66.71 \text{ kg SiC}$$

Calculating the percent yield:

$$\% \text{ yield of SiC} = \frac{\text{actual yield}}{\text{theoretical yield}} \times 100 = \frac{51.4 \text{ kg SiC}}{66.71 \text{ kg SiC}} \times 100 = 77.0\%$$

Check Rounding shows that the mass of SiC seems correct: $\sim 1500 \text{ mol} \times 40 \text{ g/mol} \times 1 \text{ kg}/1000 \text{ g} = 60 \text{ kg}$. The molar ratio of SiC/ SiO_2 is 1/1, and $\mathcal{M}$ of SiC is about two-thirds ($\sim \frac{40}{60}$) of $\mathcal{M}$ of SiO_2 , so 100 kg of SiO_2 should form about 66 kg of SiC.

Road Map

FOLLOW-UP PROBLEMS

3.17A Marble (calcium carbonate) reacts with hydrochloric acid solution to form calcium chloride solution, water, and carbon dioxide. Find the percent yield of carbon dioxide if 3.65 g is collected when 10.0 g of marble reacts.

3.17B Lead(II) iodide is a bright yellow, solid compound used in the manufacture of solar cells and in photography. It is obtained by reacting aqueous solutions of potassium iodide and lead(II) nitrate; a solution of potassium nitrate is the other product. If the reaction has a 90.0% yield, calculate the mass (g) of lead(II) iodide that forms when 112 g of potassium iodide reacts with excess lead(II) nitrate.

SOME SIMILAR PROBLEMS 3.93–3.96

Starting with 100 g
of 1,2-dichlorobenzene ...

Figure 3.11 Low overall yield in a multistep synthesis.

Yields in Multistep Syntheses In the multistep synthesis of a complex compound, the overall yield can be surprisingly low, even if the yield of each step is high. For example, suppose a six-step synthesis has a 90.0% yield for each step. To find the overall percent yield, *express the yield of each step as a decimal, multiply all the decimal amounts together, and then convert back to a percentage*. The overall yield in this case is only slightly more than 50%:

$$\text{Overall \% yield} = (0.900 \times 0.900 \times 0.900 \times 0.900 \times 0.900 \times 0.900) \times 100 = 53.1\%$$

Such multistep sequences are common in laboratory syntheses of medicines, dyes, pesticides, and many other organic compounds. For example, the antidepressant Sertraline is prepared from a simple starting compound in six steps, with yields of 80%, 80%, 50%, 100%, 48%, and 30%, respectively, and an overall percent yield of only 4.6% (Figure 3.11). Because a typical synthesis begins with large amounts of inexpensive, simple reactants and ends with small amounts of expensive, complex products, the overall yield greatly influences the commercial potential of a product.

Atom Economy: A Green Chemistry Perspective on Yield In the field of **green chemistry**, academic, industrial, and government chemists develop methods that reduce or prevent the release of harmful substances into the environment and the wasting of energy resources.

One way that green chemists evaluate a synthetic route is to focus on its *atom economy*, the proportion of reactant atoms that end up in the desired product. The efficiency of a synthesis is quantified in terms of the *percent atom economy*:

$$\% \text{ atom economy} = \frac{\text{mass of atoms in desired product}}{\text{mass of atoms in all reactants}} \times 100$$

Consider two synthetic routes—one starting with benzene (C_6H_6), the other with butane (C_4H_{10})—for the production of maleic anhydride ($\text{C}_4\text{H}_2\text{O}_3$), a key substance in the manufacture of polymers, dyes, medicines, pesticides, and other products:

Let's compare the efficiency of these routes in terms of percent atom economy:

Route 1:

$$\begin{aligned} \% \text{ atom economy} &= \frac{2 \times \mathcal{M} \text{ of } \text{C}_4\text{H}_2\text{O}_3}{(2 \times \mathcal{M} \text{ of } \text{C}_6\text{H}_6) + (9 \times \mathcal{M} \text{ of } \text{O}_2)} \times 100 \\ &= \frac{2 \times 98.06 \text{ g}}{(2 \times 78.11 \text{ g}) + (9 \times 32.00 \text{ g})} \times 100 \\ &= 44.15\% \end{aligned}$$

Route 2:

$$\begin{aligned} \% \text{ atom economy} &= \frac{2 \times \mathcal{M} \text{ of } \text{C}_4\text{H}_2\text{O}_3}{(2 \times \mathcal{M} \text{ of } \text{C}_4\text{H}_{10}) + (7 \times \mathcal{M} \text{ of } \text{O}_2)} \times 100 \\ &= \frac{2 \times 98.06 \text{ g}}{(2 \times 58.12 \text{ g}) + (7 \times 32.00 \text{ g})} \times 100 \\ &= 57.64\% \end{aligned}$$

From the perspective of atom economy, route 2 is preferable, because a larger percentage of reactant atoms end up in the desired product. It is also a “greener” approach than route 1, because it avoids the use of the toxic reactant benzene and does not produce CO_2 , a gas that contributes to global warming.

› Summary of Section 3.4

- › The substances in a balanced equation are related to each other by stoichiometrically equivalent molar ratios, which are used as conversion factors to find the amount (mol) of one substance given the amount of another.
- › In limiting-reactant problems, the quantities of two (or more) reactants are given, and the limiting reactant is the one that forms the lower quantity of product. Reaction tables show the initial and final quantities of all reactants and products, as well as the changes in those quantities.
- › In practice, side reactions, incomplete reactions, and physical losses result in an actual yield of product that is less than the theoretical yield (the quantity based on the molar ratio from the balanced equation), giving a percent yield less than 100%. In multistep reaction sequences, the overall yield is found by multiplying the yields for each step.
- › Atom economy, or the proportion of reactant atoms found in the product, is one criterion for choosing a “greener” reaction process.

CHAPTER REVIEW GUIDE

Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

Understand These Concepts

1. The definition of the mole unit (§3.1)
2. The relationship between the mass of a chemical entity (in amu) and the mass of a mole of that entity (in g) (§3.1)
3. The relationships between amount of substance (in mol), mass (in g), and number of chemical entities (§3.1)
4. Mole-mass-number information in a chemical formula (§3.1)
5. The difference between empirical and molecular formulas of a compound (§3.2)
6. How more than one substance can have the same empirical formula or the same molecular formula (isomers) (§3.2)
7. The importance of balancing equations for the quantitative study of chemical reactions (§3.3)
8. Mole-mass-number information in a balanced equation (§3.4)
9. The relationship between amounts of reactants and amounts of products (§3.4)
10. Why one reactant limits the amount of product (§3.4)
11. The causes of lower-than-expected yields and the distinction between theoretical and actual yields (§3.4)

Master These Skills

1. Calculating the molar mass of any substance (§3.1; SPs 3.4, 3.5)
2. Converting between amount of substance (in moles), mass (in grams), and number of chemical entities (SPs 3.1–3.4)
3. Using mass percent to find the mass of an element in a given mass of compound (SPs 3.5, 3.6)
4. Determining empirical and molecular formulas of a compound from mass percents and molar masses of elements (SPs 3.7, 3.8)
5. Determining a molecular formula from combustion analysis (SP 3.9)
6. Converting a chemical statement or a molecular depiction into a balanced equation (SPs 3.10, 3.11)
7. Using stoichiometrically equivalent molar ratios to convert between amounts of reactants and products in reactions (SPs 3.12, 3.13)
8. Solving limiting-reactant problems for reactions (SPs 3.14–3.16)
9. Calculating percent yield (SP 3.17)

Key Terms

Page numbers appear in parentheses.

actual yield (123)	combustion analysis (105)	molar mass ($\mathcal{M}$) (94)	reactant (108)
Avogadro's number (94)	empirical formula (102)	mole (mol) (93)	side reaction (123)
balancing (stoichiometric)	green chemistry (124)	molecular formula (102)	stoichiometry (93)
coefficient (108)	isomer (103)	percent yield (% yield) (123)	structural formula (103)
chemical equation (108)	limiting reactant (116)	product (108)	theoretical yield (123)

Key Equations and Relationships

Page numbers appear in parentheses.

3.1 Number of entities in 1 mole (94):

1 mol contains 6.022×10^{23} entities (to 4 sf)3.2 Converting amount (mol) to mass (g) using $\mathcal{M}$ (95):

$$\text{Mass (g)} = \text{amount (mol)} \times \frac{\text{no. of grams}}{1 \text{ mol}} = n \times \mathcal{M}$$

3.3 Converting mass (g) to amount (mol) (96):

$$\text{Amount (mol)} = \text{mass (g)} \times \frac{1 \text{ mol}}{\text{no. of grams}} = \frac{\text{mass}}{\mathcal{M}}$$

3.4 Converting amount (mol) to number of entities (96):

$$\text{No. of entities} = \text{amount (mol)} \times \frac{6.022 \times 10^{23} \text{ entities}}{1 \text{ mol}} = n \times N_A$$

3.5 Converting number of entities to amount (mol) (96):

$$\text{Amount (mol)} = \text{no. of entities} \times \frac{1 \text{ mol}}{6.022 \times 10^{23} \text{ entities}} = \frac{\text{no. of entities}}{N_A}$$

3.6 Calculating mass % (100):

Mass % of element X

$$= \frac{\text{moles of X in formula} \times \text{molar mass of X (g/mol)}}{\text{mass (g) of 1 mol of compound}} \times 100$$

3.7 Finding the mass of an element in any mass of compound (101):

Mass of element = mass of compound

$$\times \frac{\text{mass of element in 1 mol of compound}}{\text{mass of 1 mol of compound}}$$

3.8 Calculating percent yield (123):

$$\% \text{ yield} = \frac{\text{actual yield}}{\text{theoretical yield}} \times 100$$

CHAPTER PRACTICE TEST

The answers to the Practice Test problems are shown below and the full solutions can be found in the e-book.

1. Calculate the mass % of oxygen in citric acid, show below:

- (a) 49.97% (b) 58.30% (c) 71.12%
(d) 64.47% (e) 33.33%

2. Which of the following statements is **false** for the chemical equation given below in which nitrogen gas reacts with hydrogen gas to form ammonia gas?

- (a) The reaction of 30. moles of H_2 will produce 20. moles of NH_3 .
(b) The reaction of 2.5 moles of N_2 will produce five moles of NH_3 .
(c) One molecule of N_2 requires three molecules of H_2 for complete reaction.
(d) The reaction of 14 g of N_2 produces 17 g of NH_3 .
(e) The reaction of three moles of H_2 gas will produce 17 g of NH_3 .

3. What mass of O_2 can be produced when 125 g of KO_2 reacts with excess CO_2 ?

- (a) 56.3 g (b) 93.8 g (c) 42.2 g
(d) 136 g (e) 32.9 g

4. How many moles of acetone, $\text{C}_3\text{H}_6\text{O}$, are contained in 2.44 L of acetone? The density of acetone is 0.7845 g/mL.

- (a) 131 mol (b) 42.1 mol (c) 14.6 mol
(d) 26.0 mol (e) 33.0 mol

5. How many H atoms are in 20.9 g of isopropanol (rubbing alcohol), $\text{C}_3\text{H}_8\text{O}$?

- (a) 1.68×10^{24} (b) 2.09×10^{23} (c) 6.28×10^{23}
(d) 1.25×10^{25} (e) 2.51×10^{24}

6. A 3.500 g sample of manganese was heated in air. The resulting oxide (containing only manganese and oxygen) weighed 7.0675 g. Determine the empirical formula of the oxide.

- (a) Mn_2O_3 (b) MnO (c) MnO_2
(d) Mn_2O_7 (e) Mn_3O_4

7. Consider the following reaction

What mass of water can be produced when 13.0 g of NH_3 reacts with 15.0 g of O_2 ?

- (a) 20.6 g (b) 7.03 g (c) 10.1 g
(d) 12.7 g (e) 8.44 g

8. Calculate the mass of Cr in 550. g of Cr_2O_3 .

- (a) 286 g (b) 104 g (c) 174 g
(d) 54.0 g (e) 376 g

9. Iron(II) sulfide reacts with oxygen to form iron(III) oxide and sulfur dioxide. Writing the substances in the order given, what are the coefficients in the balanced reaction?

- (a) 2, 2, 1, 2 (b) 4, 7, 2, 4 (c) 3, 4, 1, 3
(d) 2, 5, 2, 2 (e) 4, 5, 2, 4 (f) 2, 7, 1, 2

10. Stearic acid has the following mass percent composition: 76.0% C, 12.8% H, and 11.2% O. The molar mass of this compound is 284.5 g/mol. What is the molecular formula of the compound?

- (a) $\text{C}_{18}\text{H}_{36}\text{O}_2$ (b) $\text{C}_{20}\text{H}_{42}\text{O}_2$ (c) $\text{C}_{16}\text{H}_{28}\text{O}_4$
(d) $\text{C}_9\text{H}_{18}\text{O}$ (e) $\text{C}_{10}\text{H}_6\text{O}$

Answers: 1. b; 2. e; 3. c; 4. e; 5. a; 6. d; 7. c; 8. e; 9. b; 10. a

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

$$\begin{aligned} \text{3.1A } \text{Amount (mol) of C} &= 315 \text{ mg C} \times \frac{1 \text{ g}}{10^3 \text{ mg}} \times \frac{1 \text{ mol C}}{12.01 \text{ g C}} \\ &= 2.62 \times 10^{-2} \text{ mol C} \end{aligned}$$

See Road Map 3.1A.

3.1B 14 g Al = 1 soda can provides a conversion factor between mass of Al and number of soda cans:

$$\begin{aligned} \text{Number of cans} &= 52 \text{ mol Al} \times \frac{26.98 \text{ g Al}}{1 \text{ mol Al}} \times \frac{1 \text{ can}}{14 \text{ g Al}} \\ &= 100 \text{ cans} \end{aligned}$$

See Road Map 3.1B.

Road Map 3.1A

Road Map 3.1B

$$\begin{aligned} \text{3.2A } \text{Amount (mol) of N} &= 9.72 \times 10^{21} \text{ N}_2 \text{ molecules} \\ &\times \frac{1 \text{ mol N}_2 \text{ molecules}}{6.022 \times 10^{23} \text{ N}_2 \text{ molecules}} \\ &\times \frac{2 \text{ mol N atoms}}{1 \text{ mol N}_2 \text{ molecules}} \\ &= 3.23 \times 10^{-2} \text{ mol N atoms} \end{aligned}$$

See Road Map 3.2A.

$$\begin{aligned} \text{3.2B } \text{No. of He atoms} &= 325 \text{ mol He} \times \frac{6.022 \times 10^{23} \text{ He atoms}}{1 \text{ mol He}} \\ &= 1.96 \times 10^{26} \text{ He atoms} \end{aligned}$$

See Road Map 3.2B.

$$\begin{aligned} \text{3.4A (a) Mass (g) of P}_4\text{O}_{10} &= 4.65 \times 10^{22} \text{ molecules P}_4\text{O}_{10} \\ &\times \frac{1 \text{ mol P}_4\text{O}_{10}}{6.022 \times 10^{23} \text{ molecules P}_4\text{O}_{10}} \times \frac{283.88 \text{ g P}_4\text{O}_{10}}{1 \text{ mol P}_4\text{O}_{10}} \\ &= 21.9 \text{ g P}_4\text{O}_{10} \end{aligned}$$

$$\begin{aligned} \text{(b) No. of P atoms} &= 4.65 \times 10^{22} \text{ molecules P}_4\text{O}_{10} \\ &\times \frac{4 \text{ atoms P}}{1 \text{ molecule P}_4\text{O}_{10}} \\ &= 1.86 \times 10^{23} \text{ P atoms} \end{aligned}$$

$$\begin{aligned} \text{3.4B (a) No. of formula units of Ca}_3\text{(PO}_4\text{)}_2 &= 75.5 \text{ g Ca}_3\text{(PO}_4\text{)}_2 \times \frac{1 \text{ mol Ca}_3\text{(PO}_4\text{)}_2}{310.18 \text{ g Ca}_3\text{(PO}_4\text{)}_2} \\ &\times \frac{6.022 \times 10^{23} \text{ formula units Ca}_3\text{(PO}_4\text{)}_2}{1 \text{ mol Ca}_3\text{(PO}_4\text{)}_2} \\ &= 1.47 \times 10^{23} \text{ formula units Ca}_3\text{(PO}_4\text{)}_2 \end{aligned}$$

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS (continued)

(b) No. of PO_4^{3-} ions = 1.47×10^{23} $\frac{\text{formula units } \text{Ca}_3(\text{PO}_4)_2}{1 \text{ formula unit } \text{Ca}_3(\text{PO}_4)_2}$

$$\times \frac{2 \text{ PO}_4^{3-} \text{ ions}}{1 \text{ formula unit } \text{Ca}_3(\text{PO}_4)_2}$$

$$= 2.94 \times 10^{23} \text{ PO}_4^{3-} \text{ ions}$$

3.5A Mass % of C = $\frac{6 \text{ mol C} \times \frac{12.01 \text{ g C}}{1 \text{ mol C}}}{180.16 \text{ g C}_6\text{H}_{12}\text{O}_6} \times 100$

$$= 40.00 \text{ mass \% C}$$

3.5B Mass % of Cl = $\frac{3 \text{ mol Cl} \times \frac{35.45 \text{ g Cl}}{1 \text{ mol Cl}}}{137.36 \text{ g CCl}_3\text{F}} \times 100$

$$= 77.42 \text{ mass \% Cl}$$

3.6A Mass (g) of C = $16.55 \text{ g C}_6\text{H}_{12}\text{O}_6 \times \frac{72.06 \text{ g C}}{180.16 \text{ g C}_6\text{H}_{12}\text{O}_6}$

$$= 6.620 \text{ g C}$$

3.6B Mass (g) of Cl = $2.35 \text{ kg CCl}_3\text{F} \times \frac{1000 \text{ g}}{1 \text{ kg}} \times \frac{106.35 \text{ g Cl}}{137.36 \text{ g CCl}_3\text{F}}$

$$= 1820 \text{ g Cl}$$

3.7A Amount (mol) of H = $1.23 \text{ g H} \times \frac{1 \text{ mol H}}{1.008 \text{ g H}}$

$$= 1.22 \text{ mol H}$$

Similarly, there are 0.408 mol P and 1.63 mol O.

Preliminary formula: $\text{H}_{1.22}\text{P}_{0.408}\text{O}_{1.63}$

Divide by smallest subscript:

$$\frac{\text{H}}{0.408} \frac{\text{P}}{0.408} \frac{\text{O}}{0.408} = \text{H}_{2.99}\text{P}_{1.00}\text{O}_{4.00} = \text{H}_3\text{PO}_4$$

This is phosphoric acid.

3.7B Amount (mol) of S = $2.88 \text{ g S} \times \frac{1 \text{ mol S}}{32.06 \text{ g S}}$

$$= 0.0898 \text{ mol S}$$

Amount (mol) of M = $0.0898 \text{ mol S} \times \frac{2 \text{ mol M}}{3 \text{ mol S}} = 0.0599 \text{ mol M}$

$$\text{Molar mass of M} = \frac{3.12 \text{ g M}}{0.0599 \text{ mol M}} = 52.1 \text{ g/mol}$$

M is chromium, and M_2S_3 is chromium(III) sulfide.

3.8A Assuming 100.00 g of compound, we have 95.21 g of C and 4.79 g of H:

Amount (mol) of C = $95.21 \text{ g C} \times \frac{1 \text{ mol C}}{12.01 \text{ g C}} = 7.928 \text{ mol C}$

Similarly, there is 4.75 mol H.

Preliminary formula: $\text{C}_{7.928}\text{H}_{4.75} = \text{C}_{\frac{7.928}{4.75}}\text{H}_{\frac{4.75}{4.75}} = \text{C}_{1.67}\text{H}_{1.00}$

Empirical formula: $\text{C}_{(3 \times 1.67)}\text{H}_{(3 \times 1.00)} = \text{C}_5\text{H}_3$

Whole-number multiple = $\frac{\mathcal{M} \text{ of benzo[a]pyrene}}{\mathcal{M} \text{ of empirical formula}}$

$$= \frac{252.30 \text{ g/mol}}{63.07 \text{ g/mol}} = 4$$

Molecular formula: $\text{C}_{(5 \times 4)}\text{H}_{(3 \times 4)} = \text{C}_{20}\text{H}_{12}$

3.8B Assuming 100.00 g of compound, we have 49.47 g C, 5.19 g H, 28.86 g N, and 16.48 g O:

Amount (mol) of C = $49.47 \text{ g C} \times \frac{1 \text{ mol C}}{12.01 \text{ g C}} = 4.119 \text{ mol C}$

Similarly, there are 5.15 mol H, 2.060 mol N, and 1.030 mol O.

Preliminary formula: $\text{C}_{4.119}\text{H}_{5.15}\text{N}_{2.060}\text{O}_{1.030}$

$$= \text{C}_{\frac{4.119}{1.030}}\text{H}_{\frac{5.15}{1.030}}\text{N}_{\frac{2.060}{1.030}}\text{O}_{\frac{1.030}{1.030}} = \text{C}_{4.00}\text{H}_{5.00}\text{N}_{2.00}\text{O}_{1.00}$$

Empirical formula: $\text{C}_4\text{H}_5\text{N}_2\text{O}$

Whole-number multiple = $\frac{\mathcal{M} \text{ of caffeine}}{\mathcal{M} \text{ of empirical formula}}$

$$= \frac{194.2 \text{ g/mol}}{97.10 \text{ g/mol}} = 2$$

Molecular formula: $\text{C}_{(4 \times 2)}\text{H}_{(5 \times 2)}\text{N}_{(2 \times 2)}\text{O}_{(1 \times 2)} = \text{C}_8\text{H}_{10}\text{N}_4\text{O}_2$

3.9A Mass (g) of C = $0.451 \text{ g CO}_2 \times \frac{12.01 \text{ g C}}{44.01 \text{ g CO}_2}$

$$= 0.123 \text{ g C}$$

Similarly, there is 0.00690 g H.

Mass (g) of Cl = $0.250 \text{ g} - (0.123 \text{ g} + 0.00690 \text{ g}) = 0.120 \text{ g Cl}$

Amount (mol) of elements: 0.0102 mol C; 0.00685 mol H; 0.00339 mol Cl

Empirical formula: $\text{C}_{0.0102}\text{H}_{0.00685}\text{Cl}_{0.00339}$

$$= \text{C}_{\frac{0.0102}{0.00339}}\text{H}_{\frac{0.00685}{0.00339}}\text{Cl}_{\frac{0.00339}{0.00339}} = \text{C}_3\text{H}_2\text{Cl}$$

Whole-number multiple = $\frac{\mathcal{M} \text{ of compound}}{\mathcal{M} \text{ of empirical formula}}$

$$= \frac{146.99 \text{ g/mol}}{73.50 \text{ g/mol}} = 2$$

Molecular formula: $\text{C}_{(3 \times 2)}\text{H}_{(2 \times 2)}\text{Cl}_{(1 \times 2)} = \text{C}_6\text{H}_4\text{Cl}_2$

3.9B Mass (g) of C = $3.516 \text{ g CO}_2 \times \frac{12.01 \text{ g C}}{44.01 \text{ g CO}_2}$

$$= 0.9595 \text{ g C}$$

Similarly, there is 0.1127 g H.

Mass (g) of O = $1.200 \text{ g} - (0.9595 \text{ g} + 0.1127 \text{ g}) = 0.128 \text{ g O}$

Amount (mol) of elements: 0.07989 mol C; 0.1118 mol H; 0.00800 mol O

$$\text{Empirical formula: } C_{0.07989} H_{0.1118} O_{0.00800} \\ = C_{\frac{0.07989}{0.00800}} H_{\frac{0.1118}{0.00800}} O_{\frac{0.00800}{0.00800}} = C_{10} H_{14} O$$

$$\text{Whole-number multiple} = \frac{\mathcal{M} \text{ of compound}}{\mathcal{M} \text{ of empirical formula}} \\ = \frac{300.42 \text{ g/mol}}{150.21 \text{ g/mol}} = 2$$

$$\text{Molecular formula: } C_{(10 \times 2)} H_{(14 \times 2)} O_{(1 \times 2)} = C_{20} H_{28} O_2$$

3.11A From the depiction, we have

or, $2\text{CO}(g) + \text{O}_2(g) \longrightarrow 2\text{CO}_2(g)$

3.11B From the depiction, we have

or, $\text{N}_2(g) + 3\text{H}_2(g) \longrightarrow 2\text{NH}_3(g)$

$$\text{Amount (mol) of Fe}_2\text{O}_3 = 3.60 \times 10^3 \text{ mol Fe} \times \frac{1 \text{ mol Fe}_2\text{O}_3}{2 \text{ mol Fe}} \\ = 1.80 \times 10^3 \text{ mol Fe}_2\text{O}_3$$

See Road Map 3.12A.

Amount (mol) of Ag = $32.6 \text{ g Ag}_2\text{S}$

$$\times \frac{1 \text{ mol Ag}_2\text{S}}{247.80 \text{ g Ag}_2\text{S}} \times \frac{6 \text{ mol Ag}}{3 \text{ mol Ag}_2\text{S}} \\ = 0.263 \text{ mol Ag}$$

See Road Map 3.12B.

Road Map 3.12A

Road Map 3.12B

3.13A

$$\text{No. of Al atoms} = 1.00 \text{ g Al}_2\text{O}_3 \times \frac{1 \text{ mol Al}_2\text{O}_3}{101.96 \text{ g Al}_2\text{O}_3} \\ \times \frac{2 \text{ mol Al}}{1 \text{ mol Al}_2\text{O}_3} \times \frac{6.022 \times 10^{23} \text{ Al atoms}}{1 \text{ mol Al}} \\ = 1.18 \times 10^{22} \text{ Al atoms}$$

3.13B Mass (g) of Al = $125 \text{ g Ag}_2\text{S} \times \frac{1 \text{ mol Ag}_2\text{S}}{247.80 \text{ g Ag}_2\text{S}} \\ \times \frac{2 \text{ mol Al}}{3 \text{ mol Ag}_2\text{S}} \times \frac{26.98 \text{ g Al}}{1 \text{ mol Al}} \\ = 9.07 \text{ g Al}$

For AB: Molecules of AB_2

$$= 4 \text{ molecules of AB} \times \frac{2 \text{ molecules of AB}_2}{2 \text{ molecules of AB}} \\ = 4 \text{ molecules of AB}_2$$

For B_2 : Molecules of AB_2

$$= 3 \text{ molecules of B}_2 \times \frac{2 \text{ molecules of AB}_2}{1 \text{ molecule of B}_2} \\ = 6 \text{ molecules of AB}_2$$

Thus, AB is the limiting reactant; one B_2 molecule is in excess.

For SO_2 : Molecules of SO_3

$$= 5 \text{ molecules of SO}_2 \times \frac{2 \text{ molecules of SO}_3}{2 \text{ molecules of SO}_2} \\ = 5 \text{ molecules of SO}_3$$

For O_2 : Molecules of SO_3

$$= 2 \text{ molecules of O}_2 \times \frac{2 \text{ molecules of SO}_3}{1 \text{ molecule of O}_2} \\ = 4 \text{ molecules of SO}_3$$

Thus, O_2 is the limiting reactant; one SO_2 molecule is in excess.

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS (continued)

3.15A For AB: Amount (mol) of AB₂

$$= 1.5 \cancel{\text{mol AB}} \times \frac{2 \text{ mol AB}_2}{2 \cancel{\text{mol AB}}} = 1.5 \text{ mol AB}_2$$

For B₂: Amount (mol) of AB₂

$$= 1.5 \cancel{\text{mol B}_2} \times \frac{2 \text{ mol AB}_2}{1 \cancel{\text{mol B}_2}} = 3.0 \text{ mol AB}_2$$

Therefore, 1.5 mol of AB₂ can form.**3.15B** For SO₂: Amount (mol) of SO₃ = $4.2 \cancel{\text{mol SO}_2} \times \frac{2 \text{ mol SO}_3}{2 \cancel{\text{mol SO}_2}}$

$$= 4.2 \text{ mol SO}_3$$

For O₂: Amount (mol) of SO₃ = $3.6 \cancel{\text{mol O}_2} \times \frac{2 \text{ mol SO}_3}{1 \cancel{\text{mol O}_2}}$

$$= 7.2 \text{ mol SO}_3$$

Therefore, 4.2 mol of SO₃ is produced.**3.16A** $2\text{Al}(s) + 3\text{S}(s) \longrightarrow \text{Al}_2\text{S}_3(s)$ Mass (g) of Al₂S₃ formed from 10.0 g of Al

$$= 10.0 \text{ g Al} \times \frac{1 \cancel{\text{mol Al}}}{26.98 \text{ g Al}} \times \frac{1 \cancel{\text{mol Al}_2\text{S}_3}}{2 \cancel{\text{mol Al}}} \times \frac{150.14 \text{ g Al}_2\text{S}_3}{1 \cancel{\text{mol Al}_2\text{S}_3}} \\ = 27.8 \text{ g Al}_2\text{S}_3$$

Mass (g) of Al₂S₃ formed from 15.0 g of S

$$= 15.0 \text{ g S} \times \frac{1 \cancel{\text{mol S}}}{32.06 \text{ g S}} \times \frac{1 \cancel{\text{mol Al}_2\text{S}_3}}{3 \cancel{\text{mol S}}} \times \frac{150.14 \text{ g Al}_2\text{S}_3}{1 \cancel{\text{mol Al}_2\text{S}_3}} \\ = 23.4 \text{ g Al}_2\text{S}_3$$

Thus, S is the limiting reactant, and 23.4 g of Al₂S₃ forms.

Mass (g) of Al in excess

$$= \text{initial mass of Al} - \text{mass of Al reacted}$$

$$= 10.0 \text{ g Al} - \left(15.0 \text{ g S} \times \frac{1 \cancel{\text{mol S}}}{32.06 \text{ g S}} \times \frac{2 \cancel{\text{mol Al}}}{3 \cancel{\text{mol S}}} \times \frac{26.98 \text{ g Al}}{1 \cancel{\text{mol Al}}} \right) \\ = 1.6 \text{ g Al}$$

(We would obtain the same answer if sulfur were shown more correctly as S₈.)**3.16B** $2\text{C}_4\text{H}_{10}(g) + 13\text{O}_2(g) \longrightarrow 8\text{CO}_2(g) + 10\text{H}_2\text{O}(g)$ Mass (g) of CO₂ formed from 4.65 g of C₄H₁₀

$$= 4.65 \text{ g C}_4\text{H}_{10} \times \frac{1 \cancel{\text{mol C}_4\text{H}_{10}}}{58.12 \text{ g C}_4\text{H}_{10}} \times \frac{8 \cancel{\text{mol CO}_2}}{2 \cancel{\text{mol C}_4\text{H}_{10}}} \times \frac{44.01 \text{ g CO}_2}{1 \cancel{\text{mol CO}_2}} \\ = 14.1 \text{ g CO}_2$$

Mass (g) of CO₂ formed from 10.0 g of O₂

$$= 10.0 \text{ g O}_2 \times \frac{1 \cancel{\text{mol O}_2}}{32.00 \text{ g O}_2} \times \frac{8 \cancel{\text{mol CO}_2}}{13 \cancel{\text{mol O}_2}} \times \frac{44.01 \text{ g CO}_2}{1 \cancel{\text{mol CO}_2}} \\ = 8.46 \text{ g CO}_2$$

Thus, O₂ is the limiting reactant, and 8.46 g of CO₂ forms.Mass (g) of C₄H₁₀ in excess

$$= \text{initial mass of C}_4\text{H}_{10} - \text{mass of C}_4\text{H}_{10} \text{ reacted}$$

$$= 4.65 \text{ g} \\ - \left(10.0 \text{ g O}_2 \times \frac{1 \cancel{\text{mol O}_2}}{32.00 \text{ g O}_2} \times \frac{2 \cancel{\text{mol C}_4\text{H}_{10}}}{13 \cancel{\text{mol O}_2}} \times \frac{58.12 \text{ g C}_4\text{H}_{10}}{1 \cancel{\text{mol C}_4\text{H}_{10}}} \right) \\ = 1.86 \text{ g C}_4\text{H}_{10}$$

3.17A $\text{CaCO}_3(s) + 2\text{HCl}(aq) \longrightarrow \text{CaCl}_2(aq) + \text{H}_2\text{O}(l) + \text{CO}_2(g)$

$$\text{Theoretical yield (g) of CO}_2 = 10.0 \text{ g CaCO}_3 \times \frac{1 \cancel{\text{mol CaCO}_3}}{100.09 \text{ g CaCO}_3} \\ \times \frac{1 \cancel{\text{mol CO}_2}}{1 \cancel{\text{mol CaCO}_3}} \times \frac{44.01 \text{ g CO}_2}{1 \cancel{\text{mol CO}_2}} \\ = 4.40 \text{ g CO}_2$$

$$\% \text{ yield} = \frac{\text{actual yield}}{\text{theoretical yield}} \times 100 = \frac{3.65 \text{ g CO}_2}{4.40 \text{ g CO}_2} \times 100 = 83.0\%$$

3.17B $2\text{KI}(aq) + \text{Pb}(\text{NO}_3)_2(aq) \longrightarrow \text{PbI}_2(s) + 2\text{KNO}_3(aq)$ Theoretical yield of PbI₂

$$= 112 \text{ g KI} \times \frac{1 \cancel{\text{mol KI}}}{166.0 \text{ g KI}} \times \frac{1 \cancel{\text{mol PbI}_2}}{2 \cancel{\text{mol KI}}} \times \frac{461.0 \text{ g PbI}_2}{1 \cancel{\text{mol PbI}_2}} \\ = 156 \text{ g PbI}_2$$

$$\text{Actual yield (g) of PbI}_2 = \frac{\% \text{ yield}}{100\%} (\text{theoretical yield})$$

$$= \frac{90.0\%}{100\%} (156 \text{ g PbI}_2) = 140. \text{ g PbI}_2$$

PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

The Mole

(Sample Problems 3.1 to 3.6)

Concept Review Questions

3.1 The atomic mass of Cl is 35.45 amu, and the atomic mass of Al is 26.98 amu. What are the masses in grams of 3 mol of Al atoms and of 2 mol of Cl atoms?

3.2 (a) How many moles of C atoms are in 1 mol of sucrose (C₁₂H₂₂O₁₁)?

(b) How many C atoms are in 2 mol of sucrose?

3.3 Why might the expression “1 mol of chlorine” be confusing? What change would remove any uncertainty? For what other elements might a similar confusion exist? Why?

3.4 How is the molecular mass of a compound the same as the molar mass, and how is it different?

3.5 What advantage is there to using a counting unit (the mole), rather than a mass unit, for amount of substance?

3.6 You need to calculate the number of P₄ molecules that can form from 2.5 g of Ca₃(PO₄)₂. Draw a road map for solving this and write a plan, without doing any calculations.

3.7 Each of the following balances weighs the indicated numbers of atoms of two elements:

For each balance, which element—left, right, or neither—

- Has the higher molar mass?
- Has more atoms per gram?
- Has fewer atoms per gram?
- Has more atoms per mole?

Skill-Building Exercises (grouped in similar pairs)

3.8 Calculate the molar mass of each of the following:

- $\text{Sr}(\text{OH})_2$
- N_2O_3
- NaClO_3
- Cr_2O_3

3.9 Calculate the molar mass of each of the following:

- $(\text{NH}_4)_3\text{PO}_4$
- CH_2Cl_2
- $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$
- BrF_3

3.10 Calculate the molar mass of each of the following:

- SnO
- BaF_2
- $\text{Al}_2(\text{SO}_4)_3$
- MnCl_2

3.11 Calculate the molar mass of each of the following:

- N_2O_4
- $\text{C}_4\text{H}_9\text{OH}$
- $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$
- $\text{Ca}(\text{C}_2\text{H}_3\text{O}_2)_2$

3.12 Calculate each of the following quantities:

- Mass (g) of 0.346 mol of Zn
- Number of F atoms in 2.62 mol of F_2
- Number of Ca atoms in 28.5 g of Ca

3.13 Calculate each of the following quantities:

- Amount (mol) of Mn atoms in 62.0 mg of Mn
- Amount (mol) for 1.36×10^{22} atoms of Cu
- Mass (g) of 8.05×10^{24} Li atoms

3.14 Calculate each of the following quantities:

- Mass (g) of 0.68 mol of KMnO_4
- Amount (mol) of O atoms in 8.18 g of $\text{Ba}(\text{NO}_3)_2$
- Number of O atoms in 7.3×10^{-3} g of $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$

3.15 Calculate each of the following quantities:

- Mass (kg) of 4.6×10^{21} molecules of NO_2
- Amount (mol) of Cl atoms in 0.0615 g of $\text{C}_2\text{H}_4\text{Cl}_2$
- Number of H^+ ions in 5.82 g of SrH_2

3.16 Calculate each of the following quantities:

- Mass (g) of 6.44×10^{-2} mol of MnSO_4
- Amount (mol) of compound in 15.8 kg of $\text{Fe}(\text{ClO}_4)_3$
- Number of N atoms in 92.6 mg of NH_4NO_2

3.17 Calculate each of the following quantities:

- Total number of ions in 38.1 g of SrF_2
- Mass (kg) of 3.58 mol of $\text{CuCl}_2 \cdot 2\text{H}_2\text{O}$
- Mass (mg) of 2.88×10^{22} formula units of $\text{Bi}(\text{NO}_3)_3 \cdot 5\text{H}_2\text{O}$

3.18 Calculate each of the following quantities:

- Mass (g) of 8.35 mol of copper(I) carbonate
- Mass (g) of 4.04×10^{20} molecules of dinitrogen pentoxide
- Amount (mol) and number of formula units in 78.9 g of sodium perchlorate
- Number of sodium ions, perchlorate ions, chlorine atoms, and oxygen atoms in the mass of compound in part (c)

3.19 Calculate each of the following quantities:

- Mass (g) of 8.42 mol of chromium(III) sulfate decahydrate
- Mass (g) of 1.83×10^{24} molecules of dichlorine heptoxide
- Amount (mol) and number of formula units in 6.2 g of lithium sulfate
- Number of lithium ions, sulfate ions, sulfur atoms, and oxygen atoms in the mass of compound in part (c)

3.20 Calculate each of the following:

- Mass % of H in ammonium bicarbonate
- Mass % of O in sodium dihydrogen phosphate heptahydrate

3.21 Calculate each of the following:

- Mass % of I in strontium periodate
- Mass % of Mn in potassium permanganate

3.22 Calculate each of the following:

- Mass fraction of C in cesium acetate
- Mass fraction of O in uranyl sulfate trihydrate (the uranyl ion is UO_2^{2+})

3.23 Calculate each of the following:

- Mass fraction of Cl in calcium chlorate
- Mass fraction of N in dinitrogen trioxide

Problems in Context

3.24 Oxygen is required for the metabolic combustion of foods. Calculate the number of atoms in 38.0 g of oxygen gas, the amount absorbed from the lungs in about 15 min when a person is at rest.

3.25 Cisplatin (*below*), or Platinol, is used in the treatment of certain cancers. Calculate (a) the amount (mol) of compound in 285.3 g of cisplatin; (b) the number of hydrogen atoms in 0.98 mol of cisplatin.

3.26 Allyl sulfide (*below*) gives garlic its characteristic odor. Calculate (a) the mass (g) of 2.63 mol of allyl sulfide; (b) the number of carbon atoms in 35.7 g of allyl sulfide.

3.27 Iron reacts slowly with oxygen and water to form a compound commonly called rust ($\text{Fe}_2\text{O}_3 \cdot 4\text{H}_2\text{O}$). For 45.2 kg of rust, calculate (a) moles of compound; (b) moles of Fe_2O_3 ; (c) grams of Fe.

3.28 Propane is widely used in liquid form as a fuel for barbecue grills and camp stoves. For 85.5 g of propane, calculate (a) moles of compound; (b) grams of carbon.

3.29 The effectiveness of a nitrogen fertilizer is determined mainly by its mass % N. Rank the following fertilizers, most effective first: potassium nitrate; ammonium nitrate; ammonium sulfate; urea, $\text{CO}(\text{NH}_2)_2$.

3.30 The mineral galena is composed of lead(II) sulfide and has an average density of 7.46 g/cm^3 . (a) How many moles of lead(II) sulfide are in 1.00 ft^3 of galena? (b) How many lead atoms are in 1.00 dm^3 of galena?

3.31 Hemoglobin, a protein in red blood cells, carries O_2 from the lungs to the body's cells. Iron (as ferrous ion, Fe^{2+}) makes up 0.33 mass % of hemoglobin. If the molar mass of hemoglobin is $6.8 \times 10^4 \text{ g/mol}$, how many Fe^{2+} ions are in one molecule?

Determining the Formula of an Unknown Compound

(Sample Problems 3.7 to 3.9)

Concept Review Questions

3.32 What is the difference between an empirical formula and a molecular formula? Can they ever be the same?

3.33 List three ways compositional data may be given in a problem that involves finding an empirical formula.

3.34 Which of the following sets of information allows you to obtain the molecular formula of a covalent compound? In each case that allows it, explain how you would proceed (draw a road map and write a plan for a solution).

- (a) Number of moles of each type of atom in a given sample of the compound
- (b) Mass % of each element and the total number of atoms in a molecule of the compound
- (c) Mass % of each element and the number of atoms of one element in a molecule of the compound
- (d) Empirical formula and mass % of each element
- (e) Structural formula

3.35 Is MgCl_2 an empirical or a molecular formula for magnesium chloride? Explain.

Skill-Building Exercises (grouped in similar pairs)

3.36 What are the empirical formula and empirical formula mass for each of the following compounds?

- (a) C_2H_4 (b) $\text{C}_2\text{H}_6\text{O}_2$ (c) N_2O_5 (d) $\text{Ba}_3(\text{PO}_4)_2$ (e) Te_4I_{16}

3.37 What are the empirical formula and empirical formula mass for each of the following compounds?

- (a) C_4H_8 (b) $\text{C}_3\text{H}_6\text{O}_3$ (c) P_4O_{10} (d) $\text{Ga}_2(\text{SO}_4)_3$ (e) Al_2Br_6

3.38 Give the name, empirical formula, and molar mass of the compound depicted in Figure P3.38.

3.39 Give the name, empirical formula, and molar mass of the compound depicted in Figure P3.39.

Figure P3.38

Figure P3.39

3.40 What is the molecular formula of each compound?

- (a) Empirical formula CH_2 ($\mathcal{M} = 42.08 \text{ g/mol}$)
- (b) Empirical formula NH_2 ($\mathcal{M} = 32.05 \text{ g/mol}$)
- (c) Empirical formula NO_2 ($\mathcal{M} = 92.02 \text{ g/mol}$)
- (d) Empirical formula CHN ($\mathcal{M} = 135.14 \text{ g/mol}$)

3.41 What is the molecular formula of each compound?

- (a) Empirical formula CH ($\mathcal{M} = 78.11 \text{ g/mol}$)
- (b) Empirical formula $\text{C}_3\text{H}_6\text{O}_2$ ($\mathcal{M} = 74.08 \text{ g/mol}$)
- (c) Empirical formula HgCl ($\mathcal{M} = 472.1 \text{ g/mol}$)
- (d) Empirical formula $\text{C}_7\text{H}_4\text{O}_2$ ($\mathcal{M} = 240.20 \text{ g/mol}$)

3.42 Find the empirical formula of each of the following compounds: (a) 0.063 mol of chlorine atoms combined with 0.22 mol of oxygen atoms; (b) 2.45 g of silicon combined with 12.4 g of chlorine; (c) 27.3 mass % carbon and 72.7 mass % oxygen

3.43 Find the empirical formula of each of the following compounds: (a) 0.039 mol of iron atoms combined with 0.052 mol of oxygen atoms; (b) 0.903 g of phosphorus combined with 6.99 g of bromine; (c) a hydrocarbon with 79.9 mass % carbon

3.44 An oxide of nitrogen contains 30.45 mass % N. (a) What is the empirical formula of the oxide? (b) If the molar mass is $90 \pm 5 \text{ g/mol}$, what is the molecular formula?

3.45 A chloride of silicon contains 79.1 mass % Cl. (a) What is the empirical formula of the chloride? (b) If the molar mass is 269 g/mol , what is the molecular formula?

3.46 A sample of 0.600 mol of a metal M reacts completely with excess fluorine to form 46.8 g of MF_2 .

- (a) How many moles of F are in the sample of MF_2 that forms?
- (b) How many grams of M are in this sample of MF_2 ?
- (c) What element is represented by the symbol M?

3.47 A 0.370-mol sample of a metal oxide (M_2O_3) weighs 55.4 g.

- (a) How many moles of O are in the sample?
- (b) How many grams of M are in the sample?
- (c) What element is represented by the symbol M?

3.48 Menthol ($\mathcal{M} = 156.3 \text{ g/mol}$), the strong-smelling substance in many cough drops, is a compound of carbon, hydrogen, and oxygen. When 0.1595 g of menthol was burned in a combustion apparatus, 0.449 g of CO_2 and 0.184 g of H_2O formed. What is menthol's molecular formula?

3.49 The compound dimethyl phthalate, used in insect repellants, is composed of carbon, hydrogen, and oxygen and has a molar mass of 194.2 g/mol . A 0.2572-g sample of the compound was burned in a combustion apparatus and 0.583 g of CO_2 and 0.119 g of H_2O were collected. What is the molecular formula of dimethyl phthalate?

Problems in Context

3.50 Nicotine is a poisonous, addictive compound found in tobacco. A sample of nicotine contains 6.16 mmol of C, 8.56 mmol of H, and 1.23 mmol of N [1 mmol (1 millimole) = 10^{-3} mol]. What is the empirical formula of nicotine?

3.51 Cortisol ($M = 362.47$ g/mol) is a steroid hormone involved in protein synthesis. Medically, it has a major use in reducing inflammation from rheumatoid arthritis. Cortisol is 69.6% C, 8.34% H, and 22.1% O by mass. What is its molecular formula?

3.52 Acetaminophen (*below*) is a popular nonaspirin pain reliever. What is the mass % of each element in acetaminophen?

Writing and Balancing Chemical Equations

(Sample Problems 3.10 and 3.11)

Concept Review Questions

3.53 What three types of information does a balanced chemical equation provide? How?

3.54 How does a balanced chemical equation apply the law of conservation of mass?

3.55 In the process of balancing the equation

Student I writes: $\text{Al} + \text{Cl}_2 \longrightarrow \text{AlCl}_2$

Student II writes: $\text{Al} + \text{Cl}_2 + \text{Cl} \longrightarrow \text{AlCl}_3$

Student III writes: $2\text{Al} + 3\text{Cl}_2 \longrightarrow 2\text{AlCl}_3$

Is the approach of Student I valid? Student II? Student III? Explain.

Skill-Building Exercises (grouped in similar pairs)

3.56 The scenes below represent a chemical reaction between elements A (*red*) and B (*green*):

Which best represents the balanced equation for the reaction?

- $2\text{A} + 2\text{B} \longrightarrow \text{A}_2 + \text{B}_2$
- $\text{A}_2 + \text{B}_2 \longrightarrow 2\text{AB}$
- $\text{B}_2 + 2\text{AB} \longrightarrow 2\text{B}_2 + \text{A}_2$
- $4\text{A}_2 + 4\text{B}_2 \longrightarrow 8\text{AB}$

3.57 Write a balanced equation for the following gas phase reaction (carbon is *black*, hydrogen is *white*, and fluorine is *green*):

3.58 Write balanced equations for each of the following by inserting the correct coefficients in the blanks:

- $\text{Cu}(s) + \text{S}_8(s) \longrightarrow \text{Cu}_2\text{S}(s)$
- $\text{P}_4\text{O}_{10}(s) + \text{H}_2\text{O}(l) \longrightarrow \text{H}_3\text{PO}_4(l)$
- $\text{B}_2\text{O}_3(s) + \text{NaOH}(aq) \longrightarrow \text{Na}_3\text{BO}_3(aq) + \text{H}_2\text{O}(l)$
- $\text{CH}_3\text{NH}_2(g) + \text{O}_2(g) \longrightarrow \text{CO}_2(g) + \text{H}_2\text{O}(g) + \text{N}_2(g)$

3.59 Write balanced equations for each of the following by inserting the correct coefficients in the blanks:

- $\text{Cu}(\text{NO}_3)_2(aq) + \text{KOH}(aq) \longrightarrow \text{Cu}(\text{OH})_2(s) + \text{KNO}_3(aq)$
- $\text{BCl}_3(g) + \text{H}_2\text{O}(l) \longrightarrow \text{H}_3(\text{BO}_3)(s) + \text{HCl}(g)$
- $\text{CaSiO}_3(s) + \text{HF}(g) \longrightarrow \text{SiF}_4(g) + \text{CaF}_2(s) + \text{H}_2\text{O}(l)$
- $(\text{CN})_2(g) + \text{H}_2\text{O}(l) \longrightarrow \text{H}_2\text{C}_2\text{O}_4(aq) + \text{NH}_3(g)$

3.60 Write balanced equations for each of the following by inserting the correct coefficients in the blanks:

- $\text{SO}_2(g) + \text{O}_2(g) \longrightarrow \text{SO}_3(g)$
- $\text{Sc}_2\text{O}_3(s) + \text{H}_2\text{O}(l) \longrightarrow \text{Sc}(\text{OH})_3(s)$
- $\text{H}_3\text{PO}_4(aq) + \text{NaOH}(aq) \longrightarrow \text{Na}_2\text{HPO}_4(aq) + \text{H}_2\text{O}(l)$
- $\text{C}_6\text{H}_{10}\text{O}_5(s) + \text{O}_2(g) \longrightarrow \text{CO}_2(g) + \text{H}_2\text{O}(g)$

3.61 Write balanced equations for each of the following by inserting the correct coefficients in the blanks:

- $\text{As}_4\text{S}_6(s) + \text{O}_2(g) \longrightarrow \text{As}_4\text{O}_6(s) + \text{SO}_2(g)$
- $\text{Ca}_3(\text{PO}_4)_2(s) + \text{SiO}_2(s) + \text{C}(s) \longrightarrow \text{P}_4(g) + \text{CaSiO}_3(l) + \text{CO}(g)$
- $\text{Fe}(s) + \text{H}_2\text{O}(g) \longrightarrow \text{Fe}_3\text{O}_4(s) + \text{H}_2(g)$
- $\text{S}_2\text{Cl}_2(l) + \text{NH}_3(g) \longrightarrow \text{S}_4\text{N}_4(s) + \text{S}_8(s) + \text{NH}_4\text{Cl}(s)$

3.62 Convert the following into balanced equations:

- When gallium metal is heated in oxygen gas, it melts and forms solid gallium(III) oxide.
- Liquid hexane burns in oxygen gas to form carbon dioxide gas and water vapor.
- When solutions of calcium chloride and sodium phosphate are mixed, solid calcium phosphate forms and sodium chloride remains in solution.

3.63 Convert the following into balanced equations:

- When lead(II) nitrate solution is added to potassium iodide solution, solid lead(II) iodide forms and potassium nitrate solution remains.

(b) Liquid disilicon hexachloride reacts with water to form solid silicon dioxide, hydrogen chloride gas, and hydrogen gas.

(c) When nitrogen dioxide is bubbled into water, a solution of nitric acid forms and gaseous nitrogen monoxide is released.

Problem in Context

3.64 Loss of atmospheric ozone has led to an ozone “hole” over Antarctica. The loss occurs in part through three consecutive steps:

(1) Chlorine atoms react with ozone (O_3) to form chlorine monoxide and molecular oxygen.

(2) Chlorine monoxide forms ClOOCl .

(3) ClOOCl absorbs sunlight and breaks into chlorine atoms and molecular oxygen.

(a) Write a balanced equation for each step.

(b) Write an overall balanced equation for the sequence.

Calculating Quantities of Reactant and Product

(Sample Problems 3.12 to 3.17)

Concept Review Questions

3.65 What does the term *stoichiometrically equivalent molar ratio* mean, and how is it applied in solving problems?

3.66 Percent yields are generally calculated from masses. Would the result be the same if amounts (mol) were used instead? Why?

Skill-Building Exercises (grouped in similar pairs)

3.67 Reactants A and B form product C. Draw a road map and write a plan to find the mass (g) of C when 25 g of A reacts with excess B.

3.68 Reactants D and E form product F. Draw a road map and write a plan to find the mass (g) of F when 27 g of D reacts with 31 g of E.

3.69 Chlorine gas can be made in the laboratory by the reaction of hydrochloric acid and manganese(IV) oxide:

When 1.82 mol of HCl reacts with excess MnO_2 , how many

(a) moles of Cl_2 and (b) grams of Cl_2 form?

3.70 Bismuth oxide reacts with carbon to form bismuth metal:

When 0.607 mol of Bi_2O_3 reacts with excess carbon, how many

(a) moles of Bi and (b) grams of CO form?

3.71 Potassium nitrate decomposes on heating, producing potassium oxide and gaseous nitrogen and oxygen:

To produce 56.6 kg of oxygen, how many (a) moles of KNO_3 and (b) grams of KNO_3 must be heated?

3.72 Chromium(III) oxide reacts with hydrogen sulfide (H_2S) gas to form chromium(III) sulfide and water:

To produce 421 g of Cr_2S_3 , how many (a) moles of Cr_2O_3 and (b) grams of Cr_2O_3 are required?

3.73 Calculate the mass (g) of each product formed when 43.82 g of diborane (B_2H_6) reacts with excess water:

3.74 Calculate the mass (g) of each product formed when 174 g of silver sulfide reacts with excess hydrochloric acid:

3.75 Elemental phosphorus occurs as tetratomic molecules, P_4 . What mass (g) of chlorine gas is needed to react completely with 455 g of phosphorus to form phosphorus pentachloride?

3.76 Elemental sulfur occurs as octatomic molecules, S_8 . What mass (g) of fluorine gas is needed to react completely with 17.8 g of sulfur to form sulfur hexafluoride?

3.77 Calculate the mass of iodine needed to prepare 2.45 kg of iodine trichloride:

3.78 In the following reaction, how many metric tons of sulfur dioxide form for every metric ton (t) of lead obtained (1 t = 1000 kg)?

3.79 The scene below represents a mixture of A_2 (blue) and B_2 (green) before they react to form AB_3 .

(a) What is the limiting reactant?

(b) How many molecules of product can form?

3.80 The following scene shows a mixture of nitrogen (blue) and hydrogen (white) before they react to produce ammonia, NH_3 . What is the limiting reactant? Draw a scene that shows the number of reactant and product molecules present after reaction.

3.81 Methanol, CH_3OH , is produced from the reaction of carbon monoxide and hydrogen:

How many moles of methanol can be produced when 4.5 mol of CO reacts with 7.2 mol of H_2 ?

3.82 In the following reaction, 2.35 mol of NH_3 reacts with 2.75 mol of O_2 ; how many moles of water form?

3.83 Many metals react with oxygen gas to form the metal oxide. For example, calcium reacts as follows:

You wish to calculate the mass (g) of calcium oxide that can be prepared from 4.20 g of Ca and 2.80 g of O_2 .

- What amount (mol) of CaO can be produced from the given mass of Ca?
- What amount (mol) of CaO can be produced from the given mass of O_2 ?
- Which is the limiting reactant?
- How many grams of CaO can be produced?

3.84 Metal hydrides react with water to form hydrogen gas and the metal hydroxide. For example,

You wish to calculate the mass (g) of hydrogen gas that can be prepared from 5.70 g of SrH_2 and 4.75 g of H_2O .

- What amount (mol) of H_2 can be produced from the given mass of SrH_2 ?
- What amount (mol) of H_2 can be produced from the given mass of H_2O ?
- Which is the limiting reactant?
- How many grams of H_2 can be produced?

3.85 Calculate the maximum numbers of moles and grams of iodic acid (HIO_3) that can form when 635 g of iodine trichloride reacts with 118.5 g of water:

How many grams of the excess reactant remain?

3.86 Calculate the maximum numbers of moles and grams of H_2S that can form when 158 g of aluminum sulfide reacts with 131 g of water:

How many grams of the excess reactant remain?

3.87 When 0.100 mol of carbon is burned in a closed vessel with 8.00 g of oxygen, how many grams of carbon dioxide can form? Which reactant is in excess, and how many grams of it remain after the reaction?

3.88 A mixture of 0.0375 g of hydrogen and 0.0185 mol of oxygen in a closed container is sparked to initiate a reaction. How many grams of water can form? Which reactant is in excess, and how many grams of it remain after the reaction?

3.89 Aluminum nitrite and ammonium chloride react to form aluminum chloride, nitrogen, and water. How many grams of each substance are present after 72.5 g of aluminum nitrite and 58.6 g of ammonium chloride react completely?

3.90 Calcium nitrate and ammonium fluoride react to form calcium fluoride, dinitrogen monoxide, and water vapor. How many grams of each substance are present after 16.8 g of calcium nitrate and 17.50 g of ammonium fluoride react completely?

3.91 Two successive reactions, $\text{A} \longrightarrow \text{B}$ and $\text{B} \longrightarrow \text{C}$, have yields of 73% and 68%, respectively. What is the overall percent yield for conversion of A to C?

3.92 Two successive reactions, $\text{D} \longrightarrow \text{E}$ and $\text{E} \longrightarrow \text{F}$, have yields of 48% and 73%, respectively. What is the overall percent yield for conversion of D to F?

3.93 What is the percent yield of a reaction in which 45.5 g of tungsten(VI) oxide (WO_3) reacts with excess hydrogen gas to produce metallic tungsten and 9.60 mL of water ($d = 1.00 \text{ g/mL}$)?

3.94 What is the percent yield of a reaction in which 200. g of phosphorus trichloride reacts with excess water to form 128 g of HCl and aqueous phosphorous acid (H_3PO_3)?

3.95 When 20.5 g of methane and 45.0 g of chlorine gas undergo a reaction that has a 75.0% yield, what mass (g) of chloromethane (CH_3Cl) forms? Hydrogen chloride also forms.

3.96 When 56.6 g of calcium and 30.5 g of nitrogen gas undergo a reaction that has a 93.0% yield, what mass (g) of calcium nitride forms?

Problems in Context

3.97 Cyanogen, $(\text{CN})_2$, has been observed in the atmosphere of Titan, Saturn's largest moon, and in the gases of interstellar nebulas. On Earth, it is used as a welding gas and a fumigant. In its reaction with fluorine gas, carbon tetrafluoride and nitrogen trifluoride gases are produced. What mass (g) of carbon tetrafluoride forms when 60.0 g of each reactant is used?

3.98 Gaseous dichlorine monoxide decomposes readily to chlorine (*green*) and oxygen (*red*) gases.

(a) Which scene best depicts the product mixture after the decomposition?

(b) Write the balanced equation for the decomposition.

(c) If each oxygen atom represents 0.050 mol, how many molecules of dichlorine monoxide were present before the decomposition?

3.99 An intermediate step in the production of nitric acid involves the reaction of ammonia with oxygen gas to form nitrogen monoxide and water. How many grams of nitrogen monoxide can form in the reaction of 485 g of ammonia with 792 g of oxygen?

3.100 Butane gas is compressed and used as a liquid fuel in disposable cigarette lighters and lightweight camping stoves. Suppose a lighter contains 5.50 mL of butane ($d = 0.579 \text{ g/mL}$).

(a) How many grams of oxygen are needed to burn the butane completely?

(b) How many moles of H_2O form when all the butane burns?

(c) How many total molecules of gas form when the butane burns completely?

3.101 Sodium borohydride (NaBH_4) is used industrially in many organic syntheses. One way to prepare it is by reacting sodium hydride with gaseous diborane (B_2H_6). Assuming an 88.5% yield, how many grams of NaBH_4 can be prepared by reacting 7.98 g of sodium hydride and 8.16 g of diborane?

Comprehensive Problems

3.102 The mole is defined in terms of the carbon-12 atom. Use the definition to find (a) the mass in grams equal to 1 atomic mass unit; (b) the ratio of the gram to the atomic mass unit.

3.103 The first sulfur-nitrogen compound was prepared in 1835 and has been used to synthesize many others. In the early 1980s, researchers made another such compound that conducts electricity like a metal. Mass spectrometry of the compound shows a molar mass of 184.27 g/mol, and analysis shows it to contain 2.288 g of S for every 1.000 g of N. What is its molecular formula?

3.104 Hydroxyapatite, $\text{Ca}_5(\text{PO}_4)_3(\text{OH})$, is the main mineral component of dental enamel, dentin, and bone. Coating the compound on metallic implants (such as titanium alloys and stainless steels) helps the body accept the implant. When placed in bone voids, the powder encourages natural bone to grow into the void. Hydroxyapatite is prepared by adding aqueous phosphoric acid to a dilute slurry of calcium hydroxide. (a) Write a balanced equation for this preparation. (b) What mass (g) of hydroxyapatite could form from 100. g of 85% phosphoric acid and 100. g of calcium hydroxide?

3.105 Narceine is a narcotic in opium that crystallizes from solution as a hydrate that contains 10.8 mass % water and has a molar mass of 499.52 g/mol. Determine x in narceine $\cdot x\text{H}_2\text{O}$.

3.106 Hydrogen-containing fuels have a “fuel value” based on their mass % H. Rank the following compounds from highest fuel value to lowest (carbon is *black*, hydrogen is *white*, and oxygen is *red*): ethane, propane, benzene, ethanol, cetyl palmitate (whale oil, $\text{C}_{32}\text{H}_{64}\text{O}_2$).

3.107 Serotonin ($M = 176$ g/mol) transmits nerve impulses between neurons. It contains 68.2% C, 6.86% H, 15.9% N, and 9.08% O by mass. What is its molecular formula?

3.108 In 1961, scientists agreed that the atomic mass unit (amu) would be defined as $\frac{1}{12}$ the mass of an atom of ^{12}C . Before then, it was defined as $\frac{1}{16}$ the *average* mass of an atom of naturally occurring oxygen (a mixture of ^{16}O , ^{17}O , and ^{18}O). The current atomic mass of oxygen is 15.9994 amu. (a) Did Avogadro's number change after the definition of an amu changed and, if so, in what direction? (b) Did the definition of the mole change? (c) Did the mass of a mole of a substance change? (d) Before 1961, was Avogadro's number 6.02×10^{23} (to three significant figures), as it is today?

3.109 Convert the following descriptions into balanced equations: (a) In a gaseous reaction, hydrogen sulfide burns in oxygen to form sulfur dioxide and water vapor. (b) When crystalline potassium chlorate is heated to just above its melting point, it reacts to form two different crystalline compounds, potassium chloride and potassium perchlorate. (c) When hydrogen gas is passed over powdered iron(III) oxide, iron metal and water vapor form.

(d) The combustion of gaseous ethane in air forms carbon dioxide and water vapor.

(e) Iron(II) chloride is converted to iron(III) fluoride by treatment with chlorine trifluoride gas. Chlorine gas is also formed.

3.110 Isobutylene is a hydrocarbon used in the manufacture of synthetic rubber. When 0.847 g of isobutylene was subjected to combustion analysis, the gain in mass of the CO_2 absorber was 2.657 g and that of the H_2O absorber was 1.089 g. What is the empirical formula of isobutylene?

3.111 Elemental iron is obtained by smelting iron(III) oxide in a blast furnace. The process can be summarized as:

How many grams of carbon monoxide are required to form 45.0 metric tons (t) of iron from iron(III) oxide (1 t = 1000 kg)?

3.112 One of the compounds used to increase the octane rating of gasoline is toluene (ball-and-stick model is shown).

Suppose 20.0 mL of toluene ($d = 0.867$ g/mL) is consumed when a sample of gasoline burns in air.

(a) How many grams of oxygen are needed for complete combustion of the toluene? (b) How many total moles of gaseous products form? (c) How many molecules of water vapor form?

3.113 During studies of the reaction in Sample Problem 3.16,

a chemical engineer measured a less-than-expected yield of N_2 and discovered that the following side reaction occurs:

In one experiment, 10.0 g of NO formed when 100.0 g of each reactant was used. What is the highest percent yield of N_2 that can be expected?

3.114 A 0.652-g sample of a pure strontium halide reacts with excess sulfuric acid. The solid strontium sulfate formed is separated, dried, and found to weigh 0.755 g. What is the formula of the original halide?

3.115 The following scenes represent a chemical reaction between AB_2 and B_2 :

(a) Write a balanced equation for the reaction. (b) What is the limiting reactant? (c) How many moles of product can be made from 3.0 mol of B_2 and 5.0 mol of AB_2 ? (d) How many moles of excess reactant remain after the reaction in part (c)?

3.116 Which of the following models represent compounds having the same empirical formula? What is the empirical formula mass of this common formula (carbon is *black*, hydrogen is *white*, and oxygen is *red*)?

3.117 The zirconium oxalate $K_2Zr(C_2O_4)_3 \cdot H_2O$ was synthesized by mixing 1.68 g of $ZrOCl_2 \cdot 8H_2O$ with 5.20 g of $H_2C_2O_4 \cdot 2H_2O$ and an excess of aqueous KOH. After 2 months, 1.25 g of crystalline product was obtained, along with aqueous KCl and water. Calculate the percent yield.

3.118 Seawater is approximately 4.0% by mass dissolved ions, 85% of which are from NaCl. (a) Find the mass % of NaCl in seawater. (b) Find the mass % of Na^+ ions and of Cl^- ions in seawater.

3.119 Is each of the following statements true or false? Correct any that are false.

- A mole of one substance has the same number of atoms as a mole of any other substance.
- The theoretical yield for a reaction is based on the balanced chemical equation.
- A limiting-reactant problem is being stated when the available quantity of one of the reactants is given in moles.
- The empirical and molecular formulas of a compound are always different.

3.120 In each pair, choose the larger of the indicated quantities or state that the samples are equal:

- Entities: 0.4 mol of O_3 molecules or 0.4 mol of O atoms
- Grams: 0.4 mol of O_3 molecules or 0.4 mol of O atoms
- Moles: 4.0 g of N_2O_4 or 3.3 g of SO_2
- Grams: 0.6 mol of C_2H_4 or 0.6 mol of F_2
- Total ions: 2.3 mol of sodium chlorate or 2.2 mol of magnesium chloride
- Molecules: 1.0 g of H_2O or 1.0 g of H_2O_2
- Grams: 6.02×10^{23} atoms of ^{235}U or 6.02×10^{23} atoms of ^{238}U

3.121 For the reaction between solid tetraphosphorus trisulfide and oxygen gas to form solid tetraphosphorus decoxide and sulfur dioxide gas, write a balanced equation. Show the equation (see Table 3.3) in terms of (a) molecules, (b) moles, and (c) grams.

3.122 Hydrogen gas is considered a clean fuel because it produces only water vapor when it burns. If the reaction has a 98.8% yield, what mass (g) of hydrogen forms 105 kg of water?

3.123 Solar winds composed of free protons, electrons, and α particles bombard Earth constantly, knocking gas molecules out of the atmosphere. In this way, Earth loses about 3.0 kg of matter per second. It is estimated that the atmosphere will be gone in about 50 billion years. Use this estimate to calculate (a) the mass (kg) of Earth's atmosphere and (b) the amount (mol) of nitrogen, which makes up 75.5 mass % of the atmosphere.

3.124 Calculate each of the following quantities:

- Amount (mol) of 0.588 g of ammonium bromide
- Number of potassium ions in 88.5 g of potassium nitrate
- Mass (g) of 5.85 mol of glycerol ($C_3H_8O_3$)
- Volume (L) of 2.85 mol of chloroform ($CHCl_3$; $d = 1.48$ g/mL)
- Number of sodium ions in 2.11 mol of sodium carbonate
- Number of atoms in 25.0 μ g of cadmium
- Number of atoms in 0.0015 mol of fluorine gas

3.125 Elements X (*green*) and Y (*purple*) react according to the following equation: $X_2 + 3Y_2 \rightarrow 2XY_3$. Which molecular scene represents the product of the reaction?

3.126 Hydrocarbon mixtures are used as fuels. (a) How many grams of $CO_2(g)$ are produced by the combustion of 200. g of a mixture that is 25.0% CH_4 and 75.0% C_3H_8 by mass? (b) A 252-g gaseous mixture of CH_4 and C_3H_8 burns in excess O_2 , and 748 g of CO_2 gas is collected. What is the mass % of CH_4 in the mixture?

3.127 Nitrogen (N), phosphorus (P), and potassium (K) are the main nutrients in plant fertilizers. By industry convention, the numbers on a label refer to the mass percents of N, P_2O_5 , and K_2O , in that order. Calculate the N/P/K ratio of a 30/10/10 fertilizer in terms of moles of each element, and express it as $x/y/1.0$.

3.128 What mass percents of ammonium sulfate, ammonium hydrogen phosphate, and potassium chloride would you use to prepare 10/10/10 plant fertilizer (see Problem 3.127)?

3.129 Ferrocene, synthesized in 1951, was the first organic iron compound with Fe—C bonds. An understanding of the structure of ferrocene gave rise to new ideas about chemical bonding and led to the preparation of many useful compounds. In the combustion analysis of ferrocene, which contains only Fe, C, and H, a 0.9437-g sample produced 2.233 g of CO_2 and 0.457 g of H_2O . What is the empirical formula of ferrocene?

3.130 When carbon-containing compounds are burned in a limited amount of air, some $CO(g)$ as well as $CO_2(g)$ are produced. A gaseous product mixture is 35.0 mass % CO and 65.0 mass % CO_2 . What is the mass % of C in the mixture?

3.131 Write a balanced equation for the reaction depicted below:

If each reactant molecule represents 1.25×10^{-2} mol and the reaction yield is 87%, how many grams of Si-containing product form?

3.132 Citric acid (*below*) is concentrated in citrus fruits and plays a central metabolic role in nearly every animal and plant cell. (a) What are the molar mass and formula of citric acid? (b) How many moles of citric acid are in 1.50 qt of lemon juice ($d = 1.09$ g/mL) that is 6.82% citric acid by mass?

3.133 Nitrogen and oxygen gases contribute to acidic rainfall through a complex reaction sequence, summarized in the following reaction:

How many metric tons (t) of nitric acid form when 1350 t of atmospheric nitrogen is consumed (1 t = 1000 kg)?

3.134 Nitrogen monoxide reacts with elemental oxygen to form nitrogen dioxide. The first scene below represents an initial mixture of reactants. If the reaction has a 66% yield, which of the lower scenes (A, B, or C) best represents the final product mixture?

3.135 Fluorine is so reactive that it forms compounds with several of the noble gases.

(a) When 0.327 g of platinum is heated in fluorine, 0.519 g of a dark red, volatile solid forms. What is its empirical formula?
 (b) When 0.265 g of this red solid reacts with excess xenon gas, 0.378 g of an orange-yellow solid forms. What is the empirical formula of this compound, the first to contain a noble gas?
 (c) Fluorides of xenon can be formed by direct reaction of the elements at high pressure and temperature. Under conditions that produce only the tetra- and hexafluorides, 1.85×10^{-4} mol of xenon reacted with 5.00×10^{-4} mol of fluorine, and 9.00×10^{-6} mol of xenon was found in excess. What are the mass percents of each xenon fluoride in the product mixture?

3.136 Hemoglobin is 6.0% heme ($\text{C}_{34}\text{H}_{32}\text{FeN}_4\text{O}_4$) by mass. To remove the heme, hemoglobin is treated with acetic acid and

NaCl, which forms hemin ($\text{C}_{34}\text{H}_{32}\text{N}_4\text{O}_4\text{FeCl}$). A blood sample from a crime scene contains 0.65 g of hemoglobin. (a) How many grams of heme are in the sample? (b) How many moles of heme? (c) How many grams of Fe? (d) How many grams of hemin could be formed for a forensic chemist to measure?

3.137 Manganese is a key component of extremely hard steel. The element occurs naturally in many oxides. A 542.3-g sample of a manganese oxide has an Mn/O ratio of 1.00/1.42 and consists of braunite (Mn_2O_3) and manganosite (MnO). (a) How many grams of braunite and of manganosite are in the ore? (b) What is the $\text{Mn}^{3+}/\text{Mn}^{2+}$ ratio in the ore?

3.138 The human body excretes nitrogen in the form of urea, NH_2CONH_2 . The key step in its biochemical formation is the reaction of water with arginine to produce urea and ornithine:

(a) What is the mass % of nitrogen in urea, in arginine, and in ornithine? (b) How many grams of nitrogen can be excreted as urea when 135.2 g of ornithine is produced?

3.139 Aspirin (acetylsalicylic acid, $\text{C}_9\text{H}_8\text{O}_4$) is made by reacting salicylic acid ($\text{C}_7\text{H}_6\text{O}_3$) with acetic anhydride [$(\text{CH}_3\text{CO})_2\text{O}$]:

In one preparation, 3.077 g of salicylic acid and 5.50 mL of acetic anhydride react to form 3.281 g of aspirin. (a) Which is the limiting reactant (the density of acetic anhydride is 1.080 g/mL)? (b) What is the percent yield of this reaction? (c) What is the percent atom economy of this reaction?

3.140 The rocket fuel hydrazine (N_2H_4) is made by the three-step Raschig process, which has the following overall equation:

What is the percent atom economy of this process?

3.141 Lead(II) chromate (PbCrO_4) is used as the yellow pigment for marking traffic lanes but is banned from house paint because of the risk of lead poisoning. It is produced from chromite (FeCr_2O_4), an ore of chromium:

Lead(II) ion then replaces the K^+ ion. If a yellow paint is to have 0.511% PbCrO_4 by mass, how many grams of chromite are needed per kilogram of paint?

3.142 Ethanol ($\text{CH}_3\text{CH}_2\text{OH}$), the intoxicant in alcoholic beverages, is also used to make other organic compounds. In concentrated sulfuric acid, ethanol forms diethyl ether and water:

In a side reaction, some ethanol forms ethylene and water:

(a) If 50.0 g of ethanol yields 35.9 g of diethyl ether, what is the percent yield of diethyl ether? (b) If 45.0% of the ethanol that did not produce the ether reacts by the side reaction, what mass (g) of ethylene is produced?

3.143 When powdered zinc is heated with sulfur, a violent reaction occurs, and zinc sulfide forms:

Some of the reactants also combine with oxygen in air to form zinc oxide and sulfur dioxide. When 83.2 g of Zn reacts with 52.4 g of S_8 , 104.4 g of ZnS forms.

(a) What is the percent yield of ZnS?
(b) If all the remaining reactants combine with oxygen, how many grams of each of the two oxides form?

3.144 Cocaine ($\text{C}_{17}\text{H}_{21}\text{O}_4\text{N}$) is a natural substance found in coca leaves, which have been used for centuries as a local anesthetic and stimulant. Illegal cocaine arrives in the United States either as the pure compound or as the hydrochloride salt ($\text{C}_{17}\text{H}_{21}\text{O}_4\text{NHCl}$).

At 25°C, the salt is very soluble in water (2.50 kg/L), but cocaine is much less so (1.70 g/L).

(a) What is the maximum mass (g) of the hydrochloride salt that can dissolve in 50.0 mL of water?

(b) If the solution from part (a) is treated with NaOH, the salt is converted to cocaine. How much more water (L) is needed to dissolve it?

3.145 High-temperature superconducting oxides hold great promise in the utility, transportation, and computer industries.

(a) One superconductor is $\text{La}_{2-x}\text{Sr}_x\text{CuO}_4$. Calculate the molar masses of this oxide when $x = 0$, $x = 1$, and $x = 0.163$.

(b) Another common superconducting oxide is made by heating a mixture of barium carbonate, copper(II) oxide, and yttrium(III) oxide, followed by further heating in O_2 :

When equal masses of the three reactants are heated, which reactant is limiting?

(c) After the product in part (b) is removed, what is the mass % of each reactant in the remaining solid mixture?

4.6 The Reversibility of Reactions and the Equilibrium State

Source: Purestock/SuperStock

Concepts and Skills to Review Before You Study This Chapter

- › names and formulas of compounds (Section 2.7)
- › nature of ionic and covalent bonding (Section 2.6)
- › amount-mass-number conversions (Section 3.1)
- › balancing chemical equations (Section 3.3)
- › calculating quantities of reactants and products (Section 3.4)

Covering 70% of Earth's surface, the vast oceans regulate climate, supply us with food, provide recreation, and contribute billions in economic benefits. But to scientists who study the oceans, they are gigantic containers of water in which a myriad of chemical reactions occur, reactions that are critical to the health of marine ecosystems. On a more personal scale, thousands of reactions are taking place right now in every cell of your body, enabling you to function. With so many reactions to study, how can we describe them all? Fortunately, many reactions, especially those that occur in solution, fall into a few major classes.

IN THIS CHAPTER . . . We examine the underlying nature of three classes of reactions and the complex part that water plays in aqueous chemistry.

- › We discuss molarity as a way to express the concentration of an ionic or covalent compound in solution.
- › We visualize the molecular structure of water to learn its role as solvent, how it interacts with ionic and covalent compounds, and the nature of electrolytes.
- › We write ionic equations that represent the species in solution and the actual change that occurs when ionic compounds dissolve and react in water.
- › We describe precipitation reactions and learn how to predict when they will occur.
- › We see how acids and bases act as electrolytes, examine the reactions that occur between acids and bases, and discuss how to quantify these reactions through titration.
- › We examine oxidation-reduction (redox) reactions, which can form ionic or covalent substances. We learn how to determine oxidation numbers and use them to determine oxidizing and reducing agents and how to quantify these reactions through titration. We describe several important types of redox reactions, one of which is used to predict the relative reactivity of metals.
- › An introduction to the reversible nature of all chemical change and the nature of equilibrium previews coverage of this central topic in later chapters.

4.1 SOLUTION CONCENTRATION AND THE ROLE OF WATER AS A SOLVENT

Before looking at some reactions that take place in solution, let's learn more about solutions themselves:

- A **solution** is a homogenous mixture with a uniform composition and no visible boundaries among the components.
- A solution consists of at least one solute and a solvent.
- The **solute** is the substance that dissolves and is usually the smaller quantity.
- The **solvent** is the substance in which the solute dissolves and is usually the larger quantity. In an **aqueous solution**, water is the solvent.
- A particular solution has a specific **concentration**—the quantity of solute dissolved in a given quantity of solution (or of solvent).

Expressing Concentration in Terms of Molarity

Concentration is an *intensive* property (like density or temperature; see Section 1.5) and thus is independent of the solution volume: a 50-L tank of a solution has the *same concentration* (solute quantity/solution quantity) as a 50-mL beaker of the solution. **Molarity (*M*)** is the most common unit of concentration (Chapter 13 covers others). It expresses the concentration in units of *moles of solute per liter of solution*:

$$\text{Molarity} = \frac{\text{moles of solute}}{\text{liters of solution}} \quad \text{or} \quad M = \frac{\text{mol solute}}{\text{L soln}} \quad (4.1)$$

A solution with a concentration of 2 *M* has twice as many moles of solute as there are liters of solution: 2 mol of solute dissolved in 1 L of solution, or 4 mol of solute dissolved in 2 L of solution, or 0.50 mol of solute dissolved in 0.25 L of solution, and so on.

SAMPLE PROBLEM 4.1 | Calculating the Molarity of a Solution

Problem Glycine ($\text{C}_2\text{H}_5\text{NO}_2$) has the simplest structure of the 20 amino acids that make up the proteins in the human body. What is the molarity of a solution that contains 53.7 g of glycine dissolved in 495 mL of solution?

Plan The molarity is the number of moles of solute in each liter of solution. We convert the mass (g) of glycine (53.7 g) to amount (mol) by dividing by the molar mass. We divide that number of moles by the volume (495 mL) and convert the volume to liters to find the molarity (see the road map).

Solution Finding the amount (mol) of glycine:

$$\text{Amount (mol) of glycine} = 53.7 \text{ g glycine} \times \frac{1 \text{ mol glycine}}{75.07 \text{ g glycine}} = 0.715 \text{ mol glycine}$$

Dividing by the volume and converting the volume units to obtain molarity:

$$\text{Molarity} = \frac{0.715 \text{ mol glycine}}{495 \text{ mL soln}} \times \frac{1000 \text{ mL}}{1 \text{ L}} = 1.44 \text{ M glycine}$$

Check A quick look at the math shows about 0.7 mol of glycine in about 0.5 L of solution, so the concentration should be about 1.4 mol/L, or 1.4 *M*.

FOLLOW-UP PROBLEMS

Brief Solutions for all Follow-up Problems appear at the end of the chapter.

4.1A Calculate the molarity of the solution made when 6.97 g of KI is dissolved in enough water to give a total volume of 100. mL.

4.1B Calculate the molarity of a solution that contains 175 mg of sodium nitrate in a total volume of 15.0 mL.

SOME SIMILAR PROBLEMS 4.22(b), 4.23(c), 4.24(b), and 4.25(a)

Amount-Mass-Number Conversions Involving Solutions

Like many intensive properties, molarity can be used as a *conversion factor* between volume (L) of solution and amount (mol) of solute:

$$\frac{\text{mol solute}}{\text{L solution}} \quad \text{or} \quad \frac{\text{L solution}}{\text{mol solute}}$$

From moles of solute, we can find the mass or the number of entities of solute (Figure 4.1), as applied in Sample Problem 4.2.

Road Map

Figure 4.1 Summary of amount-mass-number relationships in solution. The amount (mol) of a substance in solution is related to the volume (L) of solution through the molarity (M ; mol/L). As always, convert the given quantity to amount (mol) first. N_A = Avogadro's number, n = number of moles, M = molar mass, M = molarity.

SAMPLE PROBLEM 4.2

Calculating Mass of Solute in a Given Volume of Solution

Problem Biochemists often study reactions in solutions containing phosphate ion, which is commonly found in cells. How many grams of solute are in 1.75 L of 0.460 M sodium hydrogen phosphate?

Plan We need the mass (g) of solute, so we multiply the known solution volume (1.75 L) by the known molarity (0.460 M) to find the amount (mol) of solute and convert it to mass (g) using the solute's molar mass (see the road map).

Solution Calculating amount (mol) of solute in solution:

$$\text{Amount (mol) of Na}_2\text{HPO}_4 = 1.75 \text{ L soln} \times \frac{0.460 \text{ mol Na}_2\text{HPO}_4}{1 \text{ L soln}} = 0.805 \text{ mol Na}_2\text{HPO}_4$$

Converting from amount (mol) of solute to mass (g):

$$\text{Mass (g) Na}_2\text{HPO}_4 = 0.805 \text{ mol Na}_2\text{HPO}_4 \times \frac{141.96 \text{ g Na}_2\text{HPO}_4}{1 \text{ mol Na}_2\text{HPO}_4} = 114 \text{ g Na}_2\text{HPO}_4$$

Check The answer seems to be correct: $\sim 1.8 \text{ L}$ of 0.5 mol/L solution contains 0.9 mol , and $150 \text{ g/mol} \times 0.9 \text{ mol} = 135 \text{ g}$, which is close to 114 g of solute.

FOLLOW-UP PROBLEMS

4.2A In biochemistry laboratories, solutions of sucrose (table sugar, $\text{C}_{12}\text{H}_{22}\text{O}_{11}$) are used in high-speed centrifuges to separate the parts of a biological cell. How many liters of 3.30 M sucrose contain 135 g of solute? Include a road map that shows how you planned the solution.

4.2B A chemist adds 40.5 mL of a 0.128 M solution of sulfuric acid to a reaction mixture. How many moles of sulfuric acid are being added? Include a road map that shows how you planned the solution.

SOME SIMILAR PROBLEMS 4.22(a), 4.22(c), 4.23(a), 4.24(a), 4.25(b), and 4.25(c)

Road Map

Preparing and Diluting Molar Solutions

Notice that the volume term in the denominator of the molarity expression in Equation 4.1 is the *solution* volume, **not** the *solvent* volume. This means that you *cannot* dissolve 1 mol of solute in 1 L of solvent to make a 1 M solution. Because the solute volume adds to the solvent volume, the total volume (solute + solvent) would be *more* than 1 L , so the concentration would be *less* than 1 M .

Figure 4.2 Laboratory preparation of molar solutions.

Source: Stephen Frisch/McGraw Hill

Preparing a Solution Correctly preparing a solution of a solid solute requires four steps. Let's prepare 0.500 L of 0.350 M nickel(II) nitrate hexahydrate $[\text{Ni}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}]$:

1. *Weigh the solid.* Calculate the mass of solid needed by converting from volume (L) to amount (mol) and then to mass (g):

$$\begin{aligned}\text{Mass (g) of solute} &= 0.500 \cancel{\text{ L soln}} \times \frac{0.350 \text{ mol Ni(NO}_3)_2 \cdot 6\text{H}_2\text{O}}{1 \cancel{\text{ L soln}}} \\ &\times \frac{290.81 \text{ g Ni(NO}_3)_2 \cdot 6\text{H}_2\text{O}}{1 \text{ mol Ni(NO}_3)_2 \cdot 6\text{H}_2\text{O}} \\ &= 50.9 \text{ g Ni(NO}_3)_2 \cdot 6\text{H}_2\text{O}\end{aligned}$$

2. *Transfer the solid.* We need 0.500 L of solution, so we choose a 500-mL volumetric flask (a flask with a fixed volume indicated by a mark on the neck), add enough distilled water to fully dissolve the solute (usually about half the final volume, or 250 mL of distilled water in this case), and transfer the solute. Wash down any solid clinging to the neck with some solvent.
3. *Dissolve the solid.* Swirl the flask until all the solute is dissolved. If necessary, wait until the solution is at room temperature. (As we discuss in Chapter 13, the solution process may be accompanied by heating or cooling.)
4. *Add solvent to the final volume.* Add distilled water to bring the solution volume to the line on the flask neck; cover and mix thoroughly again.

Figure 4.2 shows the last three steps.

Diluting a Solution A concentrated solution (higher molarity) is converted to a dilute solution (lower molarity) by adding solvent, which increases the solution volume but the amount (mol) of solute stays the same. As a result, a dilute solution contains *fewer solute particles per unit volume* and, thus, has a lower concentration than the concentrated solution. For example, consider the effect of doubling the volume when the volume of a 2 M solution is doubled (also see Figure 4.3):

$$2\text{ M} = \frac{2 \text{ moles solute}}{1 \text{ L}} \xrightarrow{\text{Add water to double the volume}} \frac{2 \text{ moles solute}}{2 \text{ L}} = 1\text{ M}$$

concentrated solution dilute solution

Chemists often prepare and store a concentrated solution (*stock solution*) and then dilute it as needed.

Figure 4.3 Converting a concentrated solution to a dilute solution.

Source: Stephen Frisch/McGraw Hill

Solving Dilution Problems To solve dilution problems, we use the fact that the amount (mol) of solute does not change during the dilution process. Therefore, once we calculate the amount of solute needed to make a particular volume of a dilute solution, we can then calculate the volume of concentrated solution that contains that amount of solute. This two-part calculation can be combined into one step using the following relationship:

$$M_{\text{dil}} \times V_{\text{dil}} = \text{amount (mol) of solute} = M_{\text{conc}} \times V_{\text{conc}} \quad (4.2)$$

where M and V are the molarity and volume of the *dilute* (subscript “dil”) and *concentrated* (subscript “conc”) solutions. In Sample Problem 4.3, we first use a two-part calculation, followed by the one-step relationship.

SAMPLE PROBLEM 4.3

Preparing a Dilute Solution from a Concentrated Solution

Problem Isotonic saline is 0.15 M aqueous NaCl. It simulates the total concentration of ions in many cellular fluids, and its uses range from cleaning contact lenses to washing red blood cells. How would you prepare 0.80 L of isotonic saline from a 6.0 M stock solution?

Plan To dilute a concentrated solution, we add only solvent, so the *moles of solute are the same in both solutions*. First, we will use a two-part calculation:

1. We know the volume (0.80 L) and molarity (0.15 M) of the dilute (dil) NaCl solution needed, so we find the amount (mol) of NaCl it contains.
2. We find the volume (L) of concentrated (conc; 6.0 M) NaCl solution that contains the same amount (mol) (see the road map). We will confirm this answer by using Equation 4.2. Once the final volume is calculated, we add solvent *up to* the final volume.

Solution Two-part calculation: finding amount (mol) of solute in dilute solution:

$$\begin{aligned} \text{Amount (mol) of NaCl in dil soln} &= 0.80 \text{ L soln} \times \frac{0.15 \text{ mol NaCl}}{1 \text{ L soln}} \\ &= 0.12 \text{ mol NaCl} \end{aligned}$$

Finding amount (mol) of solute in concentrated solution: because we add only solvent to dilute the solution,

$$\begin{aligned} \text{Amount (mol) of NaCl in dil soln} &= \text{amount (mol) of NaCl in conc soln} \\ &= 0.12 \text{ mol NaCl} \end{aligned}$$

Finding the volume (L) of concentrated solution that contains 0.12 mol of NaCl:

$$\begin{aligned} \text{Volume (L) of conc NaCl soln} &= 0.12 \text{ mol NaCl} \times \frac{1 \text{ L soln}}{6.0 \text{ mol NaCl}} \\ &= 0.020 \text{ L soln} \end{aligned}$$

To confirm, we use Equation 4.2, $M_{\text{dil}} \times V_{\text{dil}} = M_{\text{conc}} \times V_{\text{conc}}$, with $M_{\text{dil}} = 0.15 M$, $V_{\text{dil}} = 0.80 \text{ L}$, $M_{\text{conc}} = 6.0 M$, and $V_{\text{conc}} = \text{unknown}$:

$$\begin{aligned} V_{\text{conc}} &= \frac{M_{\text{dil}} \times V_{\text{dil}}}{M_{\text{conc}}} = \frac{0.15 M \times 0.80 \text{ L}}{6.0 M} \\ &= 0.020 \text{ L soln} \end{aligned}$$

To prepare 0.80 L of dilute solution, place 0.020 L of 6.0 M NaCl in a 1.0-L graduated cylinder, add distilled water (~780 mL) to the 0.80-L mark, and stir thoroughly.

Check The answer seems reasonable because a small volume of concentrated solution is used to prepare a large volume of dilute solution. Also, the ratio of volumes (0.020 L/0.80 L) is the same as the ratio of concentrations (0.15 M /6.0 M).

FOLLOW-UP PROBLEMS

4.3A A chemist dilutes 60.0 mL of 4.50 M potassium permanganate to make a 1.25 M solution. What is the final volume of the diluted solution?

4.3B A chemical engineer dilutes a stock solution of sulfuric acid by adding 25.0 m^3 of 7.50 M acid to enough water to make 500. m^3 . What is the concentration of sulfuric acid in the diluted solution, in g/mL?

SOME SIMILAR PROBLEMS 4.28 and 4.29

Road Map

In the next sample problem, we use a variation of Equation 4.2, with molecular scenes showing numbers of particles, to visualize changes in concentration.

SAMPLE PROBLEM 4.4 Visualizing Changes in Concentration

Problem The circle in the figure represents a unit volume of a solution. Draw a circle representing a unit volume of the solution after each of these changes:

(a) For every 1 mL of solution, 1 mL of solvent is added.

(b) One-third of the solvent is boiled off.

Plan Given the starting solution, we have to find the number of solute particles in a unit volume after each change. The number of particles per unit volume, N , is directly related to the number of moles per unit volume, M , so we can use a relationship similar to Equation 4.2 to find the number of particles.

(a) The volume increases, so the final solution is more dilute—fewer particles per unit volume. (b) One-third of the solvent is lost, so the final solution is more concentrated—more particles per unit volume.

Solution (a) Finding the number of particles in the dilute solution, N_{dil} :

$$N_{\text{dil}} \times V_{\text{dil}} = N_{\text{conc}} \times V_{\text{conc}}$$

where $N_{\text{conc}} = 8$ particles, $V_{\text{conc}} = 1$ mL, and $V_{\text{dil}} = 2$ mL; thus,

$$N_{\text{dil}} = N_{\text{conc}} \times \frac{V_{\text{conc}}}{V_{\text{dil}}} = 8 \text{ particles} \times \frac{1 \text{ mL}}{2 \text{ mL}} = 4 \text{ particles}$$

(b) Finding the number of particles in the concentrated solution, N_{conc} :

$$N_{\text{dil}} \times V_{\text{dil}} = N_{\text{conc}} \times V_{\text{conc}}$$

where $N_{\text{dil}} = 8$ particles, $V_{\text{dil}} = 1$ mL, and $V_{\text{conc}} = \frac{2}{3}$ mL; thus,

$$N_{\text{conc}} = N_{\text{dil}} \times \frac{V_{\text{dil}}}{V_{\text{conc}}} = 8 \text{ particles} \times \frac{1 \text{ mL}}{\frac{2}{3} \text{ mL}} = 12 \text{ particles}$$

Check In (a), the volume is doubled (from 1 mL to 2 mL), so the number of particles should be halved; $\frac{1}{2}$ of 8 is 4. In (b), the volume is $\frac{2}{3}$ of the original, so the number of particles should be $\frac{3}{2}$ of the original; $\frac{3}{2}$ of 8 is 12.

Comment In (b), we assumed that only solvent boils off. This is true with nonvolatile solutes, such as ionic compounds, but, in Chapter 13, we'll encounter solutions in which both solvent and solute are volatile.

FOLLOW-UP PROBLEMS

4.4A The circle labeled A represents a unit volume of a solution. Explain the changes that must be made to A to obtain the unit volumes in B and C.

4.4B Circle A represents a unit volume of 100. mL of a solution. Which circle (B, C, or D) best represents the unit volume after 300. mL of solvent has been added?

SOME SIMILAR PROBLEMS 4.1 and 4.3

The Polar Nature of Water

In this chapter we will focus on aqueous solutions and how the water molecule interacts with both ionic and covalent solutes. On the atomic scale, water's great solvent power arises from the *uneven distribution of electron charge* and its *bent molecular shape*, which create a *polar molecule*:

1. **Uneven charge distribution.** Recall from Section 2.6 that the electrons in a covalent bond are shared between the atoms. In a bond between identical atoms—as in H_2 , Cl_2 , O_2 —the sharing is equal and electron charge is distributed evenly between the two nuclei (symmetrical shading in the space-filling model in Figure 4.4A). In covalent bonds between different atoms, the sharing is uneven because one atom attracts the electron pair more strongly than the other atom does.

For example, in each O—H bond of water, the shared electrons are closer to the O atom because an O atom attracts electrons more strongly than an H atom does. (We'll discuss the reasons in Chapter 9.) This uneven charge distribution creates a *polar bond*, one with partially charged “poles.” In Figure 4.4B, the asymmetrical shading shows this distribution, and the δ symbol is used to indicate a partial charge. The O end is partially negative, represented by red shading and δ^- , and the H end is partially positive, represented by blue shading and δ^+ . In the ball-and-stick model in Figure 4.4C, the *polar arrow* points to the negative pole, and the arrow's tail, shaped like a plus sign, marks the positive pole. There are two polar O—H bonds in each water molecule.

2. **Bent molecular shape.** The sequence of the H—O—H atoms in water is not linear: the water molecule is bent with a bond angle of 104.5° (Figure 4.4C).

3. **Molecular polarity.** The combination of polar bonds and bent shape makes water a **polar molecule**: the region near the O atom is partially negative (there is a higher electron density), and the region between the H atoms is partially positive (there is a lower electron density) (Figure 4.4D). The H_2O molecule is still electrically neutral overall, although its electrons are distributed asymmetrically.

Figure 4.4 Electron distribution in molecules of H_2 and H_2O .

Ionic Compounds in Water

In this subsection, we consider two closely related aspects of aqueous solutions of ionic compounds—how they occur and how they behave. We also use a compound's formula to calculate the amount (mol) of each ion in solution.

How Ionic Compounds Dissolve: Replacement of Charge Attractions In an ionic solid, oppositely charged ions are held together by electrostatic attractions (see Figure 1.3C and Section 2.6). Water can separate the ions in an ionic compound by *replacing these attractions with others between several water molecules and each ion*. One of two situations occurs:

- For soluble ionic compounds, *the attractions between each type of ion and several water molecules outweigh the attractions between the ions themselves*.
- For insoluble ionic compounds, *the attraction between the cations and anions is greater than the attraction between the ions and water*.

Figure 4.5 depicts a granule of a *soluble* ionic compound in water: the negative ends of some water molecules are attracted to the cations, and the positive ends of other water molecules are attracted to the anions. Gradually, all the ions separate (dissociate), become **solvated**—surrounded closely by solvent molecules—and then move randomly in the solution. The solvent molecules prevent the cations and anions from recombining.

How Ionic Solutions Behave: Electrolytes and Electrical Conductivity When an ionic compound dissolves, the solution's *electrical conductivity*, the flow of electric current, increases dramatically. When electrodes are immersed in distilled water (Figure 4.6A) or pushed into an ionic solid (Figure 4.6B), no current flows, as shown by the unlit bulb. But when the electrodes are submerged in an aqueous solution of

Figure 4.5 An ionic compound dissolving in water. The inset shows the polar arrow and partial charges (not shown in the rest of the scene) for a water molecule.

the compound, a large current flows, as shown by the lit bulb (Figure 4.6C). Current flow implies the *movement of charged particles*: when the ionic compound dissolves, the separate solvated ions move toward the electrode of opposite charge. A substance that conducts a current when dissolved in water is an **electrolyte**. Soluble ionic compounds are *strong* electrolytes because they dissociate completely and conduct a large current.

Figure 4.6 The electrical conductivity of ionic solutions.

Source: Stephen Frisch/McGraw Hill

Calculating the Number of Moles of Ions in Solution The subscripts of the ions in the formula of an ionic compound indicate the number of moles of each ion produced when the compound dissociates. For example, when KBr, CaBr₂, and Al₂(SO₄)₃ dissolve in water to form solvated ions,

- 1 mol of KBr dissociates into 2 mol of ions—1 mol of K⁺ and 1 mol of Br[−]:

- 1 mol of CaBr₂ dissociates into 3 mol of ions—1 mol of Ca²⁺ and 2 mol of Br[−]:

- 1 mol of Al₂(SO₄)₃ dissociates into 5 mol of ions—2 mol of Al³⁺ and 3 mol of SO₄^{2−}:

(“H₂O” above the arrows means that water is the solvent, not a reactant.) Note the following:

- In CaBr₂, 2 mol of Br[−] ions are produced, not 1 mol of Br₂[−].
- In Al₂(SO₄)₃, the polyatomic ion SO₄^{2−} remains intact; polyatomic ions, whose atoms are covalently bonded, stay together as a charged unit.

Sample Problems 4.5 and 4.6 apply these ideas, first with molecular scenes and then in calculations.

SAMPLE PROBLEM 4.5

Using Molecular Scenes to Depict an Ionic Compound in Aqueous Solution

Problem The beakers contain aqueous solutions of the strong electrolyte potassium sulfate.

- (a) Which beaker best represents the compound in solution (water molecules are not shown)?
 (b) If each particle represents 0.1 mol, what is the total number of particles in solution?
 (c) If the volume of the solution is 500. mL, what is the molarity of the potassium ion?

Plan (a) We determine the formula of potassium sulfate and write an equation for 1 mol of compound dissociating into ions. Potassium sulfate is a strong electrolyte, so it dissociates completely, but, in general, *polyatomic ions remain intact in solution*. (b) We count the number of separate particles, then multiply by 0.1 mol and by Avogadro's number. (c) We count the number of particles of potassium ion, multiply by 0.1 mol, and divide by the volume of the solution.

Solution (a) The formula is K₂SO₄, so the equation is

There are two separate 1+ particles for every 2− particle; beakers A and B show 1+ and 2− particles that are not dissociated. Beaker D shows two 2− particles for every 1+ particle. The correct ratio of separate particles is shown in beaker C.

(b) There are nine particles, so we have

$$\text{No. of particles} = 9 \text{ particles} \times \frac{0.1 \text{ mol}}{1 \text{ particle}} \times \frac{6.022 \times 10^{23} \text{ particles}}{1 \text{ mol}} = 5.420 \times 10^{23} \text{ particles}$$

(c) There are six particles of K^+ :

$$6 \text{ particles} \times \frac{0.1 \text{ mol}}{1 \text{ particle}} = 0.6 \text{ mol K}^+; \quad M = \frac{0.6 \text{ mol K}^+}{500. \text{ mL}} \times \frac{1000 \text{ mL}}{1 \text{ L}} = 1.20 \text{ M}$$

Check Rounding to check the math in (b) gives $9 \times 0.1 \times 6 = 5.4$, so the answer seems correct. The number of particles is an exact number, since we actually counted them; thus, the answer can have as many significant figures as in Avogadro's number or in the volume of solution.

FOLLOW-UP PROBLEMS

4.5A (a) Which strong electrolyte is dissolved in water (water molecules not shown) in the beaker shown: LiBr , Cs_2CO_3 , or BaCl_2 ? (b) If each particle represents 0.05 mol, what mass (g) of compound was dissolved?

4.5B (a) Make a drawing similar to that in Follow-up Problem 4.5A that shows two formula units of the strong electrolyte sodium phosphate dissolved in water (without showing any water molecules). (b) When 0.40 mol of sodium phosphate is dissolved in 600. mL of water, how many moles of ions result? (c) What is the molarity of the Na^+ ion in the solution?

SOME SIMILAR PROBLEMS 4.9 and 4.10

SAMPLE PROBLEM 4.6 | Determining Amount (mol) of Ions in Solution

Problem What amount (mol) of each ion is in each solution?

- (a) 5.0 mol of iron(III) sulfate dissolved in water
 (b) 85.4 g of vanadium(III) chloride dissolved in water
 (c) 35.0 mL of 0.80 M copper(II) nitrate

Plan We write an equation that shows 1 mol of compound dissociating into ions.

(a) We multiply the number of moles of ions by 5.0. (b) We first convert grams to moles. (c) We convert molarity and volume to moles of copper(II) nitrate and use the dissociation equation to convert moles of compound to moles of ions.

Calculating amount (mol) of Fe^{3+} and SO_4^{2-} ions:

$$\text{Amount (mol) of Fe}^{3+} = 5.0 \text{ mol Fe}_2(\text{SO}_4)_3 \times \frac{2 \text{ mol Fe}^{3+}}{1 \text{ mol Fe}_2(\text{SO}_4)_3} = 10. \text{ mol Fe}^{3+}$$

$$\text{Amount (mol) of SO}_4^{2-} = 5.0 \text{ mol Fe}_2(\text{SO}_4)_3 \times \frac{3 \text{ mol SO}_4^{2-}}{1 \text{ mol Fe}_2(\text{SO}_4)_3} = 15 \text{ mol SO}_4^{2-}$$

Converting from mass (g) to amount (mol):

$$\text{Amount (mol) of VCl}_3 = 85.4 \text{ g VCl}_3 \times \frac{1 \text{ mol VCl}_3}{157.29 \text{ g VCl}_3} = 0.543 \text{ mol VCl}_3$$

$$\text{Amount (mol) of Cl}^- = 0.543 \text{ mol VCl}_3 \times \frac{3 \text{ mol Cl}^-}{1 \text{ mol VCl}_3} = 1.63 \text{ mol Cl}^-$$

0.543 mol of V^{3+} is also present, since there is 1 mol of V^{3+} per mol of VCl_3 .

Converting from volume (mL) and molarity (mol/L) to amount (mol) of compound:

$$\begin{aligned} \text{Amount (mol) of Cu(NO}_3)_2 &= 35.0 \text{ mL} \times \frac{1 \cancel{\text{L}}}{1000 \cancel{\text{mL}}} \times \frac{0.80 \text{ mol Cu(NO}_3)_2}{1 \cancel{\text{L}}} \\ &= 0.028 \text{ mol Cu(NO}_3)_2 \end{aligned}$$

$$\text{Amount (mol) of NO}_3^- = 0.028 \text{ mol Cu(NO}_3)_2 \times \frac{2 \text{ mol NO}_3^-}{1 \text{ mol Cu(NO}_3)_2} = 0.056 \text{ mol NO}_3^-$$

0.028 mol of Cu^{2+} is also present since there is 1 mol of Cu^{2+} per mol of $\text{Cu(NO}_3)_2$.

Check Round off to check the math and see if the relative numbers of moles of ions are consistent with the formula. For instance, in (a), 10. mol Fe^{3+} /15 mol SO_4^{2-} = 2 Fe^{3+} /3 SO_4^{2-} , or $\text{Fe}_2(\text{SO}_4)_3$.

FOLLOW-UP PROBLEMS

4.6A What amount (mol) of each ion is in each solution?

- (a) 2 mol of potassium perchlorate dissolved in water
- (b) 354 g of magnesium acetate dissolved in water
- (c) 125 mL of 0.270 M ammonium chromate

4.6B What amount (mol) of each ion is in each solution?

- (a) 4 mol of lithium carbonate dissolved in water
- (b) 112 g of aluminum sulfate dissolved in water
- (c) 335 mL of 1.60 M aluminum nitrate

SOME SIMILAR PROBLEMS 4.18–4.21, 4.23(b), 4.24(c), 4.26–4.27

Covalent Compounds in Water

Water dissolves many covalent (molecular) compounds also. Table sugar (sucrose, $\text{C}_{12}\text{H}_{22}\text{O}_{11}$), beverage (grain) alcohol (ethanol, $\text{CH}_3\text{CH}_2\text{OH}$), and automobile antifreeze (ethylene glycol, $\text{HOCH}_2\text{CH}_2\text{OH}$) are some familiar examples. All contain their own polar bonds, which are attracted to the polar bonds of water. However, most soluble covalent substances *do not* separate into ions but remain intact molecules. For example,

As a result, their aqueous solutions do not conduct an electric current, and these substances are **nonelectrolytes**. (As you'll see shortly, however, a small group of H-containing molecules that act as acids in aqueous solution *do* dissociate into ions.) Many other covalent substances, such as benzene (C_6H_6) and octane (C_8H_{18}), do not contain polar bonds, and these substances do not dissolve appreciably in water.

Summary of Section 4.1

- › The concentration of a solute in a solution can be expressed by molarity, which is the number of moles of solute dissolved in 1 liter of solution. A more concentrated solution (higher molarity) is converted to a more dilute solution (lower molarity) by adding solvent.
- › Molarity can be used as a conversion factor between volume of solution and amount (mol) of solute, from which you can find mass of solute.
- › Because of polar bonds and a bent shape, the water molecule is polar, and water dissolves many ionic and covalent compounds.
- › When an ionic compound dissolves, the attraction between each ion and water molecules replaces the attraction between ions. Soluble ionic compounds are electrolytes because the ions are free to move and, thus, the solution conducts electricity.
- › The formula of a soluble ionic compound shows the number of moles of each ion in solution per mole of compound dissolved.
- › Water dissolves many covalent substances that contain polar bonds. These compounds are nonelectrolytes because the molecules remain intact and, thus, the solution does not conduct electricity.

4.2 PRECIPITATION REACTIONS

Precipitation reactions, one of three important classes of chemical reactions that we will discuss in this chapter, occur commonly in both nature and commerce. Coral reefs and some gems and minerals form, in part, through this process. And the chemical industry employs precipitation methods to make several important inorganic compounds.

The Key Event: Formation of a Solid from Dissolved Ions

In a **precipitation reaction**, two soluble ionic compounds react to form an insoluble product, a **precipitate**. Precipitates form for the same reason that some ionic compounds don't dissolve: the electrostatic attraction between the ions outweighs the tendency of the ions to remain solvated and move throughout the solution. When the two solutions are mixed, the ions collide and stay together, and a solid product “comes out of solution.” Thus, the key event in a precipitation reaction is *the formation of an insoluble product through the net removal of ions from solution*.

Let's examine the precipitation reaction that occurs between solutions of silver nitrate and sodium chromate. Chemists use three types of equations to represent aqueous ionic reactions, such as precipitation reactions. Figure 4.7 depicts this reaction at

Figure 4.7 An aqueous ionic reaction and the three types of equations.

Source: Stephen Frisch/McGraw Hill

Table 4.1 | Solubility Rules for Ionic Compounds in Water

Soluble Ionic Compounds	Insoluble Exceptions
All common compounds of Group 1 ions (Li^+ , Na^+ , K^+ , etc.)	None
All common compounds of ammonium ion (NH_4^+)	None
All common nitrates (NO_3^-), acetates (CH_3COO^- or $\text{C}_2\text{H}_3\text{O}_2^-$), chlorates (ClO_3^-), and perchlorates (ClO_4^-)	None
All common chlorides (Cl^-), bromides (Br^-), and iodides (I^-)	Chlorides, bromides, and iodides of Ag^+ , Pb^{2+} , Cu^+ , and Hg_2^{2+}
All common fluorides (F^-)	PbF_2 and fluorides of Group 2
All common sulfates (SO_4^{2-})	CaSO_4 , SrSO_4 , BaSO_4 , Ag_2SO_4 , PbSO_4 , Hg_2SO_4
Insoluble Ionic Compounds	Soluble Exceptions
All common metal hydroxides	Group 1 hydroxides and $\text{Ca}(\text{OH})_2$, $\text{Sr}(\text{OH})_2$, and $\text{Ba}(\text{OH})_2$
All common carbonates (CO_3^{2-}), chromates (CrO_4^{2-}), and phosphates (PO_4^{3-})	Carbonates, chromates, and phosphates of Group 1 and NH_4^+
All common sulfides	Sulfides of Group 1, Group 2, and NH_4^+

Predicting Whether a Precipitate Will Form

To predict whether a precipitate such as Ag_2CrO_4 will form when we mix two aqueous ionic solutions, we refer to the short list of solubility rules in Table 4.1; the solubility rules tell us which ionic compounds are soluble, and thus dissociate in water, and which ionic compounds are insoluble in water. Let's see how to apply these rules.

First we'll examine the reaction depicted in Figure 4.7 and determine the solubility of the reactants and products:

AgNO_3	soluble	All common NO_3^- compounds are soluble
Na_2CrO_4	soluble	All common Group 1 compounds are soluble
Ag_2CrO_4	insoluble	Most common CrO_4^{2-} compounds are insoluble
NaNO_3	soluble	All common Group 1 compounds are soluble

Since Ag_2CrO_4 is not soluble in water, it forms as a precipitate.

Now let's see what happens when we combine aqueous solutions of KNO_3 and Na_2CrO_4 :

KNO_3	soluble	All common NO_3^- compounds are soluble
Na_2CrO_4	soluble	All common Group 1 compounds are soluble
K_2CrO_4	soluble	All common Group 1 compounds are soluble
NaNO_3	soluble	All common Group 1 compounds are soluble

Since all cation-anion combinations are soluble, no reaction occurs:

All the ions are spectator ions, so, when we eliminate them, we have no net ionic equation and no reaction has occurred.

A Type of Metathesis Reaction Another precipitation reaction is shown in Figure 4.8. In this reaction, the bright yellow PbI_2 precipitate is formed when solutions of $\text{Pb}(\text{NO}_3)_2$ and NaI are reacted:

Most iodide compounds are soluble, but PbI_2 is an exception.

Figure 4.8 The precipitation of PbI_2 , a metathesis reaction.

Source: Stephen Frisch/McGraw Hill

Reactions in which the reactant ions change partners are called *double-displacement reactions*, or **metathesis** (pronounced “meh-TA-thuh-sis”) **reactions**. Some that involve precipitation are important in industry, including the preparation of silver bromide used in black-and-white film:

The reaction that forms Ag_2CrO_4 (see Figure 4.7) is also a metathesis reaction, as are acid-base reactions (Section 4.3). Sample Problems 4.7 and 4.8 provide practice in predicting if a precipitate forms.

Student Hot Spot

Student data indicate that you may struggle with writing total and net ionic equations. Access the eBook to view an additional Learning Resource video on this topic.

SAMPLE PROBLEM 4.7

Predicting Whether a Precipitation Reaction Occurs; Writing Ionic Equations

Problem Does a reaction occur when each of these pairs of solutions is mixed? If so, write balanced molecular, total ionic, and net ionic equations, and identify the spectator ions.

(a) Potassium fluoride(aq) + strontium nitrate(aq) $\longrightarrow$

(b) Ammonium perchlorate(aq) + sodium bromide(aq) $\longrightarrow$

Plan We note the reactant ions, write the cation-anion combinations, and refer to Table 4.1 to see if any are insoluble. For the molecular equation, we predict the products and write them all as intact compounds, using the ion charges to write correct formulas. For the total ionic equation, we write the *soluble* compounds as separate ions. For the net ionic equation, we eliminate the spectator ions.

Solution (a) In addition to the reactants, the two other ion combinations are strontium fluoride and potassium nitrate. Table 4.1 shows that strontium fluoride is insoluble, so a reaction *does* occur. Writing the molecular equation:

Writing the total ionic equation:

Writing the net ionic equation:

The spectator ions are K^+ and NO_3^- .

(b) The other ion combinations are ammonium bromide and sodium perchlorate. Table 4.1 shows that ammonium, sodium, and perchlorate compounds are soluble, and all bromides are soluble except those of Ag^+ , Pb^{2+} , Cu^+ , and Hg_2^{2+} . Therefore, **no reaction occurs**. The compounds remain as solvated ions:

FOLLOW-UP PROBLEMS

4.7A Predict whether a reaction occurs, and, if so, write balanced total and net ionic equations:

(a) Iron(III) chloride(aq) + cesium phosphate(aq) $\longrightarrow$

(b) Sodium hydroxide(aq) + cadmium nitrate(aq) $\longrightarrow$

(c) Magnesium bromide(aq) + potassium acetate(aq) $\longrightarrow$

4.7B Predict whether a reaction occurs, and, if so, write balanced total and net ionic equations:

(a) Silver nitrate(aq) + barium chloride(aq) $\longrightarrow$

(b) Ammonium carbonate(aq) + potassium sulfide(aq) $\longrightarrow$

(c) Nickel(II) sulfate(aq) + lead(II) nitrate(aq) $\longrightarrow$

SOME SIMILAR PROBLEMS 4.41–4.46

SAMPLE PROBLEM 4.8

Using Molecular Depictions in Precipitation Reactions

Problem The molecular views below depict reactant solutions for a precipitation reaction (with ions shown as colored spheres and water molecules omitted for clarity):

- (a) Which compound is dissolved in beaker A: KCl, Na₂SO₄, MgBr₂, or Ag₂SO₄?
 (b) Which compound is dissolved in beaker B: NH₄NO₃, MgSO₄, Ba(NO₃)₂, or CaF₂?
 (c) Name the precipitate and the spectator ions when solutions A and B are mixed, and write balanced molecular, total ionic, and net ionic equations for any reaction.
 (d) If each particle represents 0.010 mol of ions, what is the maximum mass (g) of precipitate that can form (assuming complete reaction)?

Plan (a) and (b) From the depictions, we note the charge and number of each kind of ion and use Table 4.1 to determine the ion combinations that are soluble. (c) Once we know the combinations, Table 4.1 tells which two ions form the solid, so the other two are spectator ions. (d) This part is a limiting-reactant problem because the amounts of two species are involved. We count the number of each kind of ion that forms the solid. We multiply the number of each reactant ion by 0.010 mol and calculate the amount (mol) of product that forms from each. Whichever ion forms less is limiting, so we use the molar mass of the precipitate to find mass (g).

Solution (a) In solution A, there are two 1+ particles for each 2- particle. Therefore, the dissolved compound cannot be KCl or MgBr₂. Of the remaining two choices, Ag₂SO₄ is insoluble, so the dissolved compound must be Na₂SO₄.

(b) In solution B, there are two 1- particles for each 2+ particle. Therefore, the dissolved compound cannot be NH₄NO₃ or MgSO₄. Of the remaining two choices, CaF₂ is insoluble, so the dissolved compound must be Ba(NO₃)₂.

(c) Of the two possible ion combinations, BaSO₄ and NaNO₃, BaSO₄ is insoluble, so Na⁺ and NO₃⁻ are spectator ions.

(d) Finding the ion that is the limiting reactant:

For Ba²⁺:

$$\text{Amount (mol) of BaSO}_4 = 4 \text{ Ba}^{2+} \text{ particles} \times \frac{0.010 \text{ mol Ba}^{2+} \text{ ions}}{1 \text{ Ba}^{2+} \text{ particle}} \times \frac{1 \text{ mol BaSO}_4}{1 \text{ mol Ba}^{2+} \text{ ions}} = 0.040 \text{ mol BaSO}_4$$

For SO₄²⁻:

$$\text{Amount (mol) of BaSO}_4 = 5 \text{ SO}_4^{2-} \text{ particles} \times \frac{0.010 \text{ mol SO}_4^{2-} \text{ ions}}{1 \text{ SO}_4^{2-} \text{ particle}} \times \frac{1 \text{ mol BaSO}_4}{1 \text{ mol SO}_4^{2-} \text{ ions}} = 0.050 \text{ mol BaSO}_4$$

Therefore, Ba²⁺ ion is the limiting reactant.

Calculating the mass (g) of product (*M* of BaSO₄ = 233.39 g/mol):

$$\text{Mass (g) of BaSO}_4 = 0.040 \text{ mol BaSO}_4 \times \frac{233.39 \text{ g BaSO}_4}{1 \text{ mol BaSO}_4} = 9.3 \text{ g BaSO}_4$$

Check Counting the number of Ba^{2+} particles allows a more direct calculation for a check: four Ba^{2+} particles mean the maximum mass of BaSO_4 that can form is

$$\begin{aligned} \text{Mass(g) of BaSO}_4 &= 4 \text{ Ba}^{2+} \text{ particles} \times \frac{0.010 \text{ mol Ba}^{2+} \text{ ions}}{1 \text{ Ba}^{2+} \text{ particle}} \times \frac{1 \text{ mol BaSO}_4}{1 \text{ mol Ba}^{2+} \text{ ions}} \times \frac{233.39 \text{ g BaSO}_4}{1 \text{ mol}} \\ &= 9.3 \text{ g BaSO}_4 \end{aligned}$$

FOLLOW-UP PROBLEMS

4.8A Molecular views of the reactant solutions for a precipitation reaction are shown below (with ions represented as spheres and water molecules omitted):

- Which compound is dissolved in beaker A: $\text{Zn}(\text{NO}_3)_2$, KCl , Na_2SO_4 , or PbCl_2 ?
- Which compound is dissolved in beaker B: $(\text{NH}_4)_2\text{SO}_4$, $\text{Cd}(\text{OH})_2$, $\text{Ba}(\text{OH})_2$, or KNO_3 ?
- Name the precipitate and the spectator ions when solutions A and B are mixed, and write balanced molecular, total ionic, and net ionic equations for the reaction.
- If each particle represents 0.050 mol of ions, what is the maximum mass (g) of precipitate that can form (assuming complete reaction)?

4.8B Molecular views of the reactant solutions for a precipitation reaction are shown below (with ions represented as spheres and water molecules omitted):

- Which compound is dissolved in beaker A: Li_2CO_3 , NH_4Cl , Ag_2SO_4 , or FeS ?
- Which compound is dissolved in beaker B: $\text{Ni}(\text{OH})_2$, AgNO_3 , CaCl_2 , or BaSO_4 ?
- Name the precipitate and the spectator ions when solutions A and B are mixed, and write balanced molecular, total ionic, and net ionic equations for the reaction.
- If each particle represents 0.20 mol of ions, what is the maximum mass (g) of precipitate that can form (assuming complete reaction)?

SOME SIMILAR PROBLEMS 4.51 and 4.52

Stoichiometry of Precipitation Reactions

In Chapter 3, we saw that the amounts (mol) of reactants and products in a reaction are stoichiometrically equivalent to each other and that the molar ratios between them can be used as conversion factors to calculate the amount of one substance that reacts with, produces, or is formed from a specific amount of another substance. Solving stoichiometry problems for any reaction that takes place in solution, such as a precipitation reaction, requires the additional step of using the solution molarity (mol/L) to convert the volume of reactant or product in solution to amount (mol):

- Write a balanced equation.
- Find the amount (mol) of one substance using the volume and molarity (for a substance in solution) or using its molar mass (for a pure substance).
- Use the molar ratio to relate that amount to the stoichiometrically equivalent amount of another substance.
- Convert to the desired units.

Figure 4.9 Summary of amount-mass-number relationships for a chemical reaction in solution. N_A = Avogadro's number, n = number of moles, M = molar mass, M = molarity.

Figure 4.9 summarizes the possible relationships among quantities of substances in a reaction occurring in solution. Sample Problems 4.9 and 4.10 apply these relationships to precipitation reactions; we'll also use them for the other classes of reactions.

SAMPLE PROBLEM 4.9

Calculating Amounts of Reactants and Products in a Precipitation Reaction

Problem Magnesium is the second most abundant metal in seawater, after sodium. The first step in its industrial extraction involves the reaction of the magnesium ion with calcium hydroxide to precipitate magnesium hydroxide. What mass of magnesium hydroxide is formed when 0.180 L of 0.0155 M magnesium chloride reacts with excess calcium hydroxide?

Plan We are given the molarity (0.0155 M) and the volume (0.180 L) of magnesium chloride solution that reacts with excess calcium hydroxide, and we must find the mass of precipitate. After writing the balanced equation, we find the amount (mol) of magnesium chloride from its molarity and volume and use the molar ratio to find the amount (mol) of magnesium hydroxide that is produced. Finally, we use the molar mass to convert from amount (mol) to mass (g) of magnesium hydroxide (see the road map).

Solution Writing the balanced equation:

Finding the amount (mol) of MgCl_2 :

$$\text{Amount (mol) of MgCl}_2 = 0.180 \text{ L MgCl}_2 \times \frac{0.0155 \text{ mol MgCl}_2}{1 \text{ L MgCl}_2} = 0.00279 \text{ mol MgCl}_2$$

Using the molar ratio to convert amount (mol) of MgCl_2 to amount (mol) of $\text{Mg}(\text{OH})_2$:

$$\begin{aligned} \text{Amount (mol) of Mg}(\text{OH})_2 &= 0.00279 \text{ mol MgCl}_2 \times \frac{1 \text{ mol Mg}(\text{OH})_2}{1 \text{ mol MgCl}_2} \\ &= 0.00279 \text{ mol Mg}(\text{OH})_2 \end{aligned}$$

Converting from amount (mol) of $\text{Mg}(\text{OH})_2$ to mass (g):

$$\text{Mass (g) of Mg}(\text{OH})_2 = 0.00279 \text{ mol Mg}(\text{OH})_2 \times \frac{58.32 \text{ g Mg}(\text{OH})_2}{1 \text{ mol Mg}(\text{OH})_2} = 0.163 \text{ g Mg}(\text{OH})_2$$

Check The answer seems reasonable; rounding to check the math shows that we have $(0.2 \text{ L}) \times (0.02 \text{ M}) = 0.004 \text{ mol}$ of MgCl_2 ; due to the 1/1 molar ratio, 0.004 mol of $\text{Mg}(\text{OH})_2$ is produced.

Road Map

FOLLOW-UP PROBLEMS

4.9A It is desirable to remove calcium ion from hard water to prevent the formation of precipitates, known as *boiler scale*, that reduce heating efficiency. The calcium ion is reacted with sodium phosphate to form solid calcium phosphate, which is easier to remove than boiler scale. What volume of 0.260 M sodium phosphate is needed to react completely with 0.300 L of 0.175 M calcium chloride?

4.9B To lift fingerprints from a crime scene, a solution of silver nitrate is sprayed on a surface to react with the sodium chloride left behind by perspiration. What is the molarity of a silver nitrate solution if 45.0 mL of it reacts with excess sodium chloride to produce 0.148 g of precipitate?

SOME SIMILAR PROBLEMS 4.47, 4.48, 4.53, and 4.54

Except for the additional step of finding amounts (mol) in solution, limiting-reactant problems for precipitation reactions in solution are handled just like other such problems.

SAMPLE PROBLEM 4.10

Solving a Limiting-Reactant Problem for a Precipitation Reaction

Problem Iron(III) hydroxide, used to adsorb arsenic and heavy metals from contaminated soil and water, is produced by reacting aqueous solutions of iron(III) chloride and sodium hydroxide.

(a) What mass of iron(III) hydroxide is formed when 0.155 L of 0.250 M iron(III) chloride reacts with 0.215 L of 0.300 M sodium hydroxide?

(b) Write a reaction table for this process.

Plan This is a limiting-reactant problem because *the quantities of two reactants are given*. After balancing the equation, we determine the limiting reactant. From the molarity and volume of each solution, we calculate the amount (mol) of each reactant. Then, we use the molar ratio to find the amount of product [Fe(OH)₃] that each reactant forms. The limiting reactant forms fewer moles of Fe(OH)₃, which we convert to mass (g) of Fe(OH)₃ using its molar mass (see the road map). We use the amount of Fe(OH)₃ formed from the limiting reactant in a reaction table (see Section 3.4).

Solution (a) Writing the balanced equation:

Finding the amount (mol) of Fe(OH)₃ formed from FeCl₃: combining the steps gives

$$\begin{aligned} \text{Amount (mol) of Fe}(\text{OH})_3 &= 0.155 \text{ L soln} \times \frac{0.250 \text{ mol FeCl}_3}{1 \text{ L soln}} \times \frac{1 \text{ mol Fe}(\text{OH})_3}{1 \text{ mol FeCl}_3} \\ &= 0.0388 \text{ mol Fe}(\text{OH})_3 \end{aligned}$$

Finding the amount (mol) of Fe(OH)₃ from NaOH: combining the steps gives

$$\begin{aligned} \text{Amount (mol) of Fe}(\text{OH})_3 &= 0.215 \text{ L soln} \times \frac{0.300 \text{ mol NaOH}}{1 \text{ L soln}} \times \frac{1 \text{ mol Fe}(\text{OH})_3}{3 \text{ mol NaOH}} \\ &= 0.0215 \text{ mol Fe}(\text{OH})_3 \end{aligned}$$

NaOH is the limiting reactant because it forms fewer moles of Fe(OH)₃.

Converting the amount (mol) of Fe(OH)₃ formed from NaOH to mass (g):

$$\text{Mass (g) of Fe}(\text{OH})_3 = 0.0215 \text{ mol Fe}(\text{OH})_3 \times \frac{106.87 \text{ g Fe}(\text{OH})_3}{1 \text{ mol Fe}(\text{OH})_3} = 2.30 \text{ g Fe}(\text{OH})_3$$

(b) With NaOH as the limiting reactant, the reaction table is

Amount (mol)	FeCl ₃ (aq)	+	3NaOH(aq)	→	Fe(OH) ₃ (s)	+	3NaCl(aq)
Initial	0.0388		0.0645		0		0
Change	-0.0215		-0.0645		+0.0215		+0.0645
Final	0.0173		0		0.0215		0.0645

A large excess of FeCl₃ remains after the reaction. Note that the amount of NaCl formed is three times the amount of FeCl₃ consumed, as the balanced equation shows.

Road Map

Check As a check on our choice of the limiting reactant, let's use the alternative method outlined in the Comment in Sample Problem 3.16.

Finding amounts (mol) of reactants given:

$$\begin{aligned}\text{Amount (mol) of FeCl}_3 &= 0.155 \cancel{\text{ L soln}} \times \frac{0.250 \text{ mol FeCl}_3}{1 \cancel{\text{ L soln}}} \\ &= 0.0388 \text{ mol FeCl}_3\end{aligned}$$

$$\begin{aligned}\text{Amount (mol) of NaOH} &= 0.215 \cancel{\text{ L soln}} \times \frac{0.300 \text{ mol NaOH}}{1 \cancel{\text{ L soln}}} \\ &= 0.0645 \text{ mol NaOH}\end{aligned}$$

The molar ratio of the reactants is 1 FeCl₃/3 NaOH. Therefore, NaOH is limiting because there is less of it than the $3 \times 0.0388 = 0.116$ mol we would need to react with all of the available FeCl₃.

FOLLOW-UP PROBLEMS

4.10A Despite the toxicity of lead, many of its compounds are still used to make pigments. (a) When 268 mL of 1.50 M lead(II) acetate reacts with 130. mL of 3.40 M sodium chloride, how many grams of solid lead(II) chloride can form? (b) Using the abbreviation "Ac" for the acetate ion, write a reaction table for the process.

4.10B Mercury and its compounds have uses from fillings for teeth (as a mixture with silver, copper, and tin) to the production of chlorine. Because of their toxicity, however, soluble mercury compounds, such as mercury(II) nitrate, must be removed from industrial wastewater. One removal method reacts the wastewater with sodium sulfide solution to produce solid mercury(II) sulfide and sodium nitrate solution. In a laboratory simulation, 0.050 L of 0.010 M mercury(II) nitrate reacts with 0.020 L of 0.10 M sodium sulfide. (a) What mass of mercury(II) sulfide is formed? (b) Write a reaction table for this process.

SOME SIMILAR PROBLEMS 4.49, 4.50, and 4.56

Summary of Section 4.2

- › In a precipitation reaction, an insoluble ionic compound forms when solutions of two soluble ones are mixed. The electrostatic attraction between certain pairs of solvated ions is strong enough to overcome the attraction of each ion for water molecules.
- › Based on a set of solubility rules, we can predict the formation of a precipitate by noting which of all possible cation-anion combinations is insoluble.
- › A molecular equation shows all substances as intact and undissociated into ions.
- › A total ionic equation shows all soluble ionic compounds as separate, solvated ions. Spectator ions appear unchanged on both sides of the equation.
- › A net ionic equation eliminates the spectator ions and, thus, shows only the actual chemical change.
- › When chemical changes such as precipitation reactions occur in solution, amounts of reactants and products are given in terms of concentration and volume.
- › By using molarity as a conversion factor, we can apply the principles of stoichiometry to precipitation reactions in solution.

4.3 ACID-BASE REACTIONS

Aqueous acid-base reactions, the second class of chemical reactions that we will consider, occur in processes as diverse as the metabolic action of proteins and carbohydrates, the industrial production of fertilizer, and the revitalization of lakes damaged by acid rain.

An **acid-base reaction** (also called a **neutralization reaction**) occurs when an acid reacts with a base. *These reactions involve water as a reactant or product, in*

addition to its common role as a solvent. There are several ways to define acids and bases, but at this point, we will use the following definitions:

- An **acid** is a substance that produces H^+ ions when dissolved in water. Acids have one or more H atoms as part of their structure, which are released as protons in water:

The degree to which an acid releases its H atoms places it into one of two categories:

1. **Strong acids**, such as HNO_3 and H_2SO_4 , ionize completely in solution; all molecules of a strong acid in solution dissociate into ions.
 2. **Weak acids**, such as HF and H_3PO_4 , dissociate very little. Most of a solution of a weak acid is composed of intact, undissociated molecules; only a very small percentage of the acid molecules ionize to produce H^+ .
- A **base** is a substance that produces OH^- ions when dissolved in water. Bases are also categorized as strong or weak, depending on the extent to which they produce hydroxide ions:
 1. **Strong bases** have either OH^- (e.g., $NaOH$) or O^{2-} (e.g., K_2O) as part of their structure and dissociate completely into ions.

The O^{2-} ion is not stable in water and reacts to form OH^- ion:

2. **Weak bases**, such as ammonia (NH_3), do not contain OH^- ions, but, as you'll see in later chapters, they all have an electron pair on a nitrogen atom. That nitrogen atom attracts one of the H atoms in a water molecule. The loss of an H^+ ion from the H_2O molecule produces OH^- ions:

Weak bases dissociate very little into ions; the ionization reaction proceeds in both directions, as indicated by the double reaction arrow in the preceding equation; we'll discuss this important idea further in Section 4.6.

Table 4.2 lists the strong acids and bases and a few examples of weak acids and bases. (Other definitions for acids and bases are presented in Chapter 18.)

Acids and the Solvated Proton As just discussed, acids release protons when dissolved in water; both the proton and the anion of the acid are solvated, as shown for HBr :

The solvated H^+ ion is a very unusual species. The H atom is a proton surrounded by an electron, so H^+ is just a proton. With a full positive charge concentrated in such a tiny volume, H^+ attracts the negative pole of water molecules so strongly that it forms a covalent bond to one of them. We can show this interaction by writing the solvated H^+ ion as an H_3O^+ ion (**hydronium ion**) that also is solvated:

The hydronium ion, which we write as H_3O^+ [or $(H_2O)H^+$], associates with other water molecules to give species such as $H_5O_2^+$ [or $(H_2O)_2H^+$], $H_7O_3^+$ [or $(H_2O)_3H^+$], $H_9O_4^+$ [or $(H_2O)_4H^+$], and so forth. Figure 4.10 shows $H_7O_3^+$, an H_3O^+ ion associated (dotted lines) with two H_2O molecules. As a general notation for these various species, we write $H^+(aq)$ in this chapter, but, in much of the text, we'll use $H_3O^+(aq)$.

Table 4.2 Strong and Weak Acids and Bases

Acids

Strong

Hydrochloric acid, HCl
 Hydrobromic acid, HBr
 Hydriodic acid, HI
 Nitric acid, HNO_3
 Sulfuric acid, H_2SO_4
 Perchloric acid, $HClO_4$

Weak (a few of many examples)

Hydrofluoric acid, HF
 Phosphoric acid, H_3PO_4
 Acetic acid, $HC_2H_3O_2$ (or CH_3COOH)

Bases

Strong

Group 1 hydroxides:

Lithium hydroxide, $LiOH$
 Sodium hydroxide, $NaOH$
 Potassium hydroxide, KOH
 Rubidium hydroxide, $RbOH$
 Cesium hydroxide, $CsOH$

Heavy Group 2 hydroxides:

Calcium hydroxide, $Ca(OH)_2$
 Strontium hydroxide, $Sr(OH)_2$
 Barium hydroxide, $Ba(OH)_2$

Weak (one of many examples)

Ammonia, NH_3

Figure 4.10 The H^+ ion as a solvated hydronium ion.

A Strong acid (or base) = strong electrolyte

B Weak acid (or base) = weak electrolyte

Figure 4.11 Acids and bases as electrolytes.

Source: Stephen Frisch/McGraw Hill

Acids and Bases as Electrolytes Earlier in the chapter, we saw that substances that conduct a current when dissolved in water are called electrolytes. Soluble ionic compounds are strong electrolytes, since they dissociate completely and conduct a large current, whereas most covalent compounds are classified as nonelectrolytes, since they do not produce ions in solution. Acids and bases are also classified as electrolytes:

- *Strong acids and strong bases are strong electrolytes.* Since these compounds dissociate completely into ions, like soluble ionic compounds, they conduct a large current, as shown by the brightly lit bulb in Figure 4.11A.
- *Weak acids and weak bases are weak electrolytes.* Since these compounds dissociate very little into ions, they conduct a small current (Figure 4.11B).

Table 4.3 summarizes the categories of electrolytes.

Table 4.3 | Classification of Soluble Compounds as Electrolytes

Strong Electrolytes	Weak Electrolytes	Nonelectrolytes
Ionic compounds	Weak acids	Covalent (molecular) compounds
Strong acids	Weak bases	
Strong bases		

Because a strong acid (or strong base) dissociates completely, we can find the molarity of H^+ (or OH^-) and the amount (mol) or number of each ion in solution. (You'll see how to determine these quantities for weak acids and bases in Chapter 18.)

SAMPLE PROBLEM 4.11 | Determining the Number of H^+ (or OH^-) Ions in Solution

Problem Nitric acid is a major chemical in the fertilizer and explosives industries. How many $\text{H}^+(aq)$ ions are in 25.3 mL of 1.4 M nitric acid?

Plan We know the volume (25.3 mL) and molarity (1.4 M) of the nitric acid, and we need the number of $\text{H}^+(aq)$. We convert from mL to L and multiply by the molarity to find the amount (mol) of acid. Table 4.2 shows that nitric acid is a strong acid, so it dissociates completely. With the formula, we write a dissociation equation, which shows the amount (mol) of H^+ ions per mole of acid. We multiply that amount by Avogadro's number to find the number of $\text{H}^+(aq)$ ions (see the road map).

Solution Finding the amount (mol) of nitric acid:

$$\text{Amount (mol) of HNO}_3 = 25.3 \text{ mL} \times \frac{1 \text{ L}}{1000 \text{ mL}} \times \frac{1.4 \text{ mol}}{1 \text{ L}} = 0.035 \text{ mol}$$

Nitric acid is HNO_3 , so we have

Finding the number of H^+ ions:

$$\begin{aligned} \text{No. of H}^+ \text{ ions} &= 0.035 \text{ mol HNO}_3 \times \frac{1 \text{ mol H}^+}{1 \text{ mol HNO}_3} \times \frac{6.022 \times 10^{23} \text{ H}^+ \text{ ions}}{1 \text{ mol H}^+} \\ &= 2.1 \times 10^{22} \text{ H}^+ \text{ ions} \end{aligned}$$

Check The number of moles seems correct: $0.025 \text{ L} \times 1.4 \text{ mol/L} = 0.035 \text{ mol}$, and multiplying by 6×10^{23} ions/mol gives 2×10^{22} ions.

FOLLOW-UP PROBLEMS

4.11A How many moles of $\text{OH}^-(aq)$ ions are present in 451 mL of 0.0120 M calcium hydroxide?

4.11B How many $\text{H}^+(aq)$ ions are present in 65.5 mL of 0.722 M hydrochloric acid?

Road Map

The Key Event: Formation of H_2O from H^+ and OH^-

Like precipitation reactions, *acid-base reactions are metathesis (double-displacement) reactions*. The H^+ from the acid combines with the OH^- from the base to form water (and the cation from the base combines with the anion from the acid to form a second product). Thus, *the key event in an acid-base reaction is the formation of H_2O from H^+ and OH^- ions*. Let's examine this process with two examples.

Reaction Between Strong Acids and Strong Bases Let's write molecular, total ionic, and net ionic equations for the reaction of the strong acid HCl with the strong base NaOH :

- The molecular equation is

- HCl and NaOH dissociate completely, since they are strong electrolytes, so the total ionic equation is

- In the net ionic equation, we eliminate the spectator ions, $\text{Na}^+(aq)$ and $\text{Cl}^-(aq)$:

Notice that the spectator ion Na^+ is the cation of the strong base and the spectator ion Cl^- is the anion of the strong acid. Only the spectator ions differ from one strong acid–strong base reaction to another—the net ionic equation is *identical for the reaction of any strong acid with any strong base*.

The molecular and total ionic equations show that, if you evaporate the water, the spectator ions remain: the ionic compound that results from the reaction of an acid and a base is called a **salt**, which in this case is sodium chloride. Thus, in an aqueous neutralization reaction, *an acid and a base form a salt solution and water*:

Figure 4.12 shows this process on an atomic level.

Figure 4.12 An aqueous strong acid–strong base reaction.

Table 4.4 | Reactions of Strong and Weak Acids with a Strong Base

	Strong Acid and Strong Base	Weak Acid and Strong Base
Molecular equation	$\text{HCl}(aq) + \text{NaOH}(aq) \longrightarrow \text{NaCl}(aq) + \text{H}_2\text{O}(l)$	$\text{HC}_2\text{H}_3\text{O}_2(aq) + \text{NaOH}(aq) \longrightarrow \text{NaC}_2\text{H}_3\text{O}_2(aq) + \text{H}_2\text{O}(l)$
Total ionic equation	$\text{H}^+(aq) + \text{Cl}^-(aq) + \text{Na}^+(aq) + \text{OH}^-(aq) \longrightarrow \text{Na}^+(aq) + \text{Cl}^-(aq) + \text{H}_2\text{O}(l)$	$\text{HC}_2\text{H}_3\text{O}_2(aq) + \text{Na}^+(aq) + \text{OH}^-(aq) \longrightarrow \text{C}_2\text{H}_3\text{O}_2^-(aq) + \text{Na}^+(aq) + \text{H}_2\text{O}(l)$
Net ionic equation	$\text{H}^+(aq) + \text{OH}^-(aq) \longrightarrow \text{H}_2\text{O}(l)$	$\text{HC}_2\text{H}_3\text{O}_2(aq) + \text{OH}^-(aq) \longrightarrow \text{C}_2\text{H}_3\text{O}_2^-(aq) + \text{H}_2\text{O}(l)$

Reaction Between Weak Acids and Strong Bases The molecular equation for the reaction of a weak acid and a strong base is similar to that for the reaction of a strong acid and a strong base, but the total ionic and net ionic equations are different. As an example, we will examine the reaction of the weak acid acetic acid, $\text{HC}_2\text{H}_3\text{O}_2$, and the strong base sodium hydroxide:

- The molecular equation is

- Since acetic acid is a weak acid and, thus, *dissociates very little*, it appears on the left side of the total ionic equation as an *undissociated, intact molecule* instead of as ions:

- In the net ionic equation, we eliminate the spectator ion, $\text{Na}^+(aq)$:

There is only one spectator ion, $\text{Na}^+(aq)$, the cation of the strong base. For the reaction of *any weak acid with any strong base*, the net ionic equation has the form

Only the spectator ion from the strong base differs from one weak acid–strong base reaction to another. Table 4.4 compares the reactions of strong and weak acids with a strong base.

Gas-Forming Reactions Acids and bases react with some compounds to produce a gaseous product. Let's look at a few common examples:

- Carbonate and bicarbonates: When an ionic carbonate, such as Na_2CO_3 , or an ionic bicarbonate, such as NaHCO_3 , is treated with an acid, such as HCl , one of the products is gaseous carbon dioxide, as the molecular equations show:

Square brackets around a species, in this case H_2CO_3 , mean it is very unstable: H_2CO_3 decomposes immediately into water and carbon dioxide.

- Sulfites and bisulfites: Ionic sulfites and bisulfites react similarly to form water and gaseous SO_2 ; unstable H_2SO_3 is an intermediate product that decomposes immediately into water and $\text{SO}_2(g)$:

- Sulfides: Ionic sulfide compounds react with acids to produce hydrogen sulfide gas:

- Ammonium compounds react with strong base to produce gaseous ammonia, NH_3 :

Student Hot Spot

Student data indicate that you may struggle with reactions between weak acids and strong bases. Access the eBook to view an additional Learning Resource video on this topic.

Figure 4.13 A gas-forming reaction with a weak acid. Note that the two ionic equations include acetic acid because it does *not* dissociate appreciably into ions.
Source: Charles D. Winters/McGraw Hill

Figure 4.13 shows the reaction between vinegar (a 5% solution of acetic acid) and baking soda (sodium hydrogen carbonate) solution. In fact, when stomach acid (mostly HCl) builds up, your duodenum releases the hormone secretin, which stimulates your pancreas to release HCO_3^- ions that react with the excess acid in an analogous reaction. Bicarbonate ion is also an ingredient in some antacids.

SAMPLE PROBLEM 4.12 | Writing Ionic Equations for Acid-Base Reactions

Problem Write balanced molecular, total ionic, and net ionic equations for each of the following acid-base reactions. Identify the spectator ions. For (a) and (c), give the name of the salt present when the water evaporates. For (b), note that propanoic acid ($\text{CH}_3\text{CH}_2\text{COOH}$) is a weak acid.

- (a) Hydriodic acid(aq) + calcium hydroxide(aq) $\longrightarrow$
 (b) Potassium hydroxide(aq) + propanoic acid(aq) $\longrightarrow$
 (c) Nitric acid(aq) + potassium sulfite(aq) $\longrightarrow$

Plan (a) The reactants are a strong acid and a strong base (see Table 4.2) and thus are strong electrolytes that dissociate completely into ions. The products are H_2O and a solution of spectator ions that becomes a solid salt when the water evaporates. (b) Since the acid is weak, it occurs as intact molecules in solution. The only spectator ion is the cation of the base. (c) This is a reaction between a strong acid and an ionic sulfite to produce H_2SO_3 , which decomposes to produce water and gaseous SO_2 ; both reactants are strong electrolytes and dissociate completely into ions.

Solution (a) Writing the molecular equation:

Writing the total ionic equation:

Writing the net ionic equation:

$\text{Ca}^{2+}(aq)$ and $\text{I}^-(aq)$ are spectator ions, so the salt is calcium iodide, CaI_2 .

(b) Writing the molecular equation:

Writing the total ionic equation:

Writing the net ionic equation:

K^+ is the only spectator ion.

(c) Writing the molecular equation:

Writing the total ionic equation:

Writing the net ionic equation:

$\text{K}^+(aq)$ and $\text{NO}_3^-(aq)$ are spectator ions, so the salt is potassium nitrate.

FOLLOW-UP PROBLEMS

4.12A Write balanced total and net ionic equations for the reaction between aqueous solutions of nitrous acid (a weak acid) and strontium hydroxide. Give the name and formula of the salt that is present when the water evaporates, and identify the spectator ion(s).

4.12B Write balanced total and net ionic equations for the reaction between aqueous solutions of calcium hydrogen carbonate and hydrobromic acid. Give the name and formula of the salt that is present when the water evaporates.

SOME SIMILAR PROBLEMS 4.65–4.68

Stoichiometry of Acid-Base Reactions: Acid-Base Titrations

As we saw for precipitation reactions, the molar ratios in an acid-base reaction can also be combined with concentration and volume information to quantify the reactants and products involved in the reaction. Sample Problem 4.13 demonstrates this type of calculation.

SAMPLE PROBLEM 4.13

Calculating the Amounts of Reactants and Products in an Acid-Base Reaction

Problem Specialized cells in the stomach release HCl to aid digestion. If they release too much, the excess can be neutralized with a base in the form of an antacid. Magnesium hydroxide is a common active ingredient in antacids. As a government chemist testing commercial antacids, you use 0.10 *M* HCl to simulate the acid concentration in the stomach. How many liters of this “stomach acid” will react with a tablet containing 0.10 g of magnesium hydroxide?

Plan We are given the mass (0.10 g) of magnesium hydroxide, $\text{Mg}(\text{OH})_2$, that reacts with the acid. We also know the acid concentration (0.10 *M*) and must find the acid volume. After writing the balanced equation, we convert the mass (g) of $\text{Mg}(\text{OH})_2$ to amount (mol) and use the molar ratio to find the amount (mol) of HCl that reacts with it. Then, we use the molarity of HCl to find the volume (L) that contains this amount (see the road map).

Solution Writing the balanced equation:

Converting from mass (g) of $\text{Mg}(\text{OH})_2$ to amount (mol):

$$\begin{aligned}\text{Amount (mol) of Mg(OH)}_2 &= 0.10 \text{ g Mg(OH)}_2 \times \frac{1 \text{ mol Mg(OH)}_2}{58.32 \text{ g Mg(OH)}_2} \\ &= 1.7 \times 10^{-3} \text{ mol Mg(OH)}_2\end{aligned}$$

Converting from amount (mol) of $\text{Mg}(\text{OH})_2$ to amount (mol) of HCl:

$$\begin{aligned}\text{Amount (mol) of HCl} &= 1.7 \times 10^{-3} \text{ mol Mg(OH)}_2 \times \frac{2 \text{ mol HCl}}{1 \text{ mol Mg(OH)}_2} \\ &= 3.4 \times 10^{-3} \text{ mol HCl}\end{aligned}$$

Road Map

Converting from amount (mol) of HCl to volume (L):

$$\begin{aligned}\text{Volume (L) of HCl} &= 3.4 \times 10^{-3} \text{ mol HCl} \times \frac{1 \text{ L}}{0.10 \text{ mol HCl}} \\ &= 3.4 \times 10^{-2} \text{ L}\end{aligned}$$

Check The size of the answer seems reasonable: a small volume of dilute acid (0.034 L of 0.10 *M*) reacts with a small amount of antacid (0.0017 mol).

FOLLOW-UP PROBLEMS

4.13A Another active ingredient in some antacids is aluminum hydroxide. What mass of aluminum hydroxide is needed to react with the volume of 0.10 *M* HCl calculated in Sample Problem 4.13?

4.13B The active ingredient in an aspirin tablet is acetylsalicylic acid, $\text{HC}_9\text{H}_7\text{O}_4$, which is mixed with inert binding agents and fillers. An aspirin tablet dissolved in water requires 14.10 mL of 0.128 *M* NaOH for complete reaction of the acetylsalicylic acid. What mass of acetylsalicylic acid is in the tablet? (*Hint*: Only one proton in acetylsalicylic acid reacts with the base.)

SOME SIMILAR PROBLEMS 4.69, 4.70, 4.76, and 4.77

Quantifying Acid-Base Reactions by Titration Acid-base reactions are studied quantitatively in a laboratory procedure called a *titration*. In any **titration**, the *known concentration of one solution is used to determine the unknown concentration of another*. In a typical acid-base titration, a *standardized* solution of base, one whose concentration is *known*, is added to a solution of acid whose concentration is *unknown* (or vice versa).

Figure 4.14A shows the laboratory setup for an acid-base titration with a known volume of acid and a few drops of indicator in a flask. An *acid-base indicator* is a substance whose color is different in acid than in base; the indicator used in the figure is phenolphthalein, which is pink in base (OH^-) and colorless in acid (H^+). (We examine indicators in Chapters 18 and 19.)

- Before the titration reaction begins (Figure 4.14A), there are only H^+ ions in the flask, so the phenolphthalein is colorless.
- Base is added from a buret, and the OH^- ions react with the H^+ ions.
- As the titration nears its end (Figure 4.14B), the drop of added base creates a temporary excess of OH^- , causing some indicator molecules to change to the basic

A Before titration **B Near end point** **C At end point**

$\text{H}^+(\text{aq}) + \text{X}^-(\text{aq}) + \text{M}^+(\text{aq}) + \text{OH}^-(\text{aq}) \longrightarrow \text{H}_2\text{O}(\text{l}) + \text{M}^+(\text{aq}) + \text{X}^-(\text{aq})$

Figure 4.14 An acid-base titration.

Source: Stephen Frisch/McGraw Hill

color; they return to the acidic color when the flask is swirled and the excess OH^- reacts with H^+ .

- The **equivalence point** occurs when *the amount (mol) of H^+ ions in the original volume of acid has reacted with the same amount (mol) of OH^- ions from the buret*:

Amount (mol) of H^+ (originally in flask) = amount (mol) of OH^- (added from buret)

- The **end point** occurs when a tiny excess of OH^- ions changes the indicator permanently to its basic (pink) color (Figure 4.14C).

In calculations, such as in Sample Problem 4.14, we assume that this tiny excess of OH^- ions is insignificant and that *the amount of base needed to reach the end point is the same as the amount needed to reach the equivalence point*.

SAMPLE PROBLEM 4.14 | Finding the Concentration of an Acid from a Titration

Problem To standardize an H_2SO_4 solution, you put 50.00 mL of it in a flask with a few drops of indicator and put 0.1524 M NaOH in a buret. The buret reads 0.55 mL at the start and 33.87 mL at the end point. Find the molarity of the H_2SO_4 solution.

Plan We have to find the molarity of the acid from the volume of acid (50.00 mL), the initial (0.55 mL) and final (33.87 mL) volumes of base, and the molarity of the base (0.1524 M). First, we balance the equation. The volume of added base is the difference in buret readings, and we use the base's molarity to calculate the amount (mol) of base. Then, we use the molar ratio from the balanced equation to find the amount (mol) of acid originally present and divide by the acid's original volume to find the molarity (see the road map).

Solution Writing the balanced equation:

Finding the volume (L) of NaOH solution added:

$$\begin{aligned}\text{Volume (L) of solution} &= (33.87 \text{ mL soln} - 0.55 \text{ mL soln}) \times \frac{1 \text{ L}}{1000 \text{ mL}} \\ &= 0.03332 \text{ L soln}\end{aligned}$$

Finding the amount (mol) of NaOH added:

$$\begin{aligned}\text{Amount (mol) of NaOH} &= 0.03332 \text{ L soln} \times \frac{0.1524 \text{ mol NaOH}}{1 \text{ L soln}} \\ &= 5.078 \times 10^{-3} \text{ mol NaOH}\end{aligned}$$

Finding the amount (mol) of H_2SO_4 originally present: since the molar ratio is 2 mol NaOH/1 mol H_2SO_4 ,

$$\begin{aligned}\text{Amount (mol) of H}_2\text{SO}_4 &= 5.078 \times 10^{-3} \text{ mol NaOH} \times \frac{1 \text{ mol H}_2\text{SO}_4}{2 \text{ mol NaOH}} \\ &= 2.539 \times 10^{-3} \text{ mol H}_2\text{SO}_4\end{aligned}$$

Calculating the molarity of H_2SO_4 :

$$\text{Molarity of H}_2\text{SO}_4 = \frac{2.539 \times 10^{-3} \text{ mol H}_2\text{SO}_4}{50.00 \text{ mL}} \times \frac{1000 \text{ mL}}{1 \text{ L}} = 0.05078 \text{ M H}_2\text{SO}_4$$

Check The answer makes sense: a large volume of less concentrated acid neutralized a small volume of more concentrated base. With rounding, the numbers of moles of H^+ and OH^- are about equal: $50 \text{ mL} \times 2(0.05 \text{ M}) \text{ H}^+ = 0.005 \text{ mol} = 33 \text{ mL} \times 0.15 \text{ M OH}^-$.

FOLLOW-UP PROBLEMS

4.14A What volume of 0.1292 M $\text{Ba}(\text{OH})_2$ would neutralize 50.00 mL of a 0.1000 M HCl solution?

4.14B Calculate the molarity of a solution of KOH if 18.15 mL of it is required for the titration of a 20.00-mL sample of a 0.2452 M HNO_3 solution.

4.4 OXIDATION-REDUCTION (REDOX) REACTIONS

The last major class of chemical reactions that we will consider are oxidation-reduction (redox) reactions, which include the formation of a compound from its elements (and the reverse process), all combustion processes, the generation of electricity in batteries, the production of cellular energy, and many others. In fact, redox reactions are so widespread that many do not occur in solution at all. In this section, we examine the key event in the redox process, discuss important terminology, see how to determine whether a reaction involves a redox process, and learn how to quantify redox reactions. (The redox reactions in this section can be balanced by methods you learned in Chapter 3; you'll learn how to balance more complex ones when we discuss electrochemistry in Chapter 21.)

The Key Event: Movement of Electrons Between Reactants

The key chemical event in an **oxidation-reduction** (or **redox**) **reaction** is the *net movement of electrons from one reactant to another*. The movement occurs from the reactant (or atom in the reactant) with *less* attraction for electrons to the reactant (or atom) with *more* attraction for electrons.

This process occurs in the formation of both ionic and covalent compounds:

- **Ionic compounds: transfer of electrons.** In the reaction that forms MgO from its elements (see Figure 3.6), the balanced equation is

Figure 4.15A shows that each Mg atom loses two electrons and each O atom gains them. This loss and gain is a **transfer of electrons** away from each Mg atom to each O atom. The resulting Mg^{2+} and O^{2-} ions aggregate into an ionic solid.

- **Covalent compounds: shift of electrons.** During the formation of a covalent compound from its elements, there is more a **shift of electrons**, rather than a full transfer. Thus, *ions do not form*. Consider the formation of HCl gas:

To see the electron movement, we'll compare the electron distribution in reactant and product. As Figure 4.15B shows, in H_2 and Cl_2 , the electrons are shared equally between the atoms (*symmetrical shading*). Because the Cl atom attracts electrons more than the H atom, in HCl , the electrons are shared unequally (*asymmetrical shading*). Electrons shift away from H and toward Cl , so the Cl atom has more negative charge (*red* and δ^-) in HCl than it had in Cl_2 , and the H atom has less negative charge (*blue* and δ^+) than it had in H_2 . Thus, H_2 loses some electron charge and Cl_2 gains some electron charge.

Figure 4.15 The redox process in the formation of (A) ionic and (B) covalent compounds from their elements.

Some Essential Redox Terminology

Certain key terms describe the process and explain the name of this reaction class:

- **Oxidation** is the *loss* of electrons.
- **Reduction** is the *gain* of electrons.

During the formation of MgO, Mg undergoes oxidation (loss of electrons), and O₂ undergoes reduction (gain of electrons). The loss and gain are simultaneous, but we can imagine them occurring separately:

(Throughout this discussion, **blue** type indicates **oxidation**, and **red** type **reduction**.)

- The **oxidizing agent** is the species doing the oxidizing (causing the electron loss).
- The **reducing agent** is the species doing the reducing (causing the electron gain).

One reactant acts on the other, with a give-and-take of electrons. This means that

- *The oxidizing agent is reduced:* it takes electrons (and, thus, gains them).
- *The reducing agent is oxidized:* it gives up electrons (and, thus, loses them).

Table 4.5 summarizes these concepts for the two reactions shown in Figure 4.15.

Table 4.5 | Terms in Oxidation-Reduction Reactions

2Mg(s) + O₂(g) → 2MgO(s)	
Mg loses electrons to form Mg ²⁺	O ₂ gain electrons to form O ²⁻
Mg is <i>oxidized</i>	O ₂ is <i>reduced</i>
Mg transfers electrons to O ₂	O ₂ takes electrons from Mg
Mg causes the reduction of O ₂	O ₂ causes the oxidation of Mg
Mg is the <i>reducing agent</i>	O ₂ is the <i>oxidizing agent</i>
H₂(g) + Cl₂(g) → 2HCl(g)	
H loses some electron charge	Cl gains some electron charge
H ₂ is <i>oxidized</i>	Cl ₂ is <i>reduced</i>
H provides electron charge to Cl	Cl takes electron charge from H
H ₂ causes the reduction of Cl ₂	Cl ₂ causes the oxidation of H ₂
H ₂ is the <i>reducing agent</i>	Cl ₂ is the <i>oxidizing agent</i>

Using Oxidation Numbers to Monitor Electron Charge

Chemists have devised a “bookkeeping” system to monitor which atom loses electron charge and which atom gains it: each atom in a molecule (or formula unit) is assigned an **oxidation number (O.N.)**, or *oxidation state*, which is the charge the atom would have *if* its electrons were transferred completely, not shared:

- Each element in a binary *ionic* compound has a *full charge* because the atom transferred its electron(s), and so the atom's oxidation number equals the ionic charge. Thus, in MgO , the oxidation number of the Mg^{2+} ion is +2 and the oxidation number of the O^{2-} ion is -2.
- Each element in a *covalent* compound (or in a polyatomic ion) has a *partial charge* because the electrons shifted away from one atom and toward the other. For these cases, we determine oxidation number by a set of rules, presented in Table 4.6 (you'll learn the atomic basis of the rules in Chapters 8 and 9).
- An O.N. has the sign *before* the number (e.g., +2), whereas an ionic charge has the sign *after* the number (e.g., $2+$). Also, unlike a unitary ionic charge, as in Na^+ or Cl^- , an O.N. of +1 or -1 retains the numeral. For example, we don't write the sodium ion as Na^{1+} , but the O.N. of the Na^+ ion is +1, not +.

Table 4.6 | Rules for Assigning an Oxidation Number (O.N.)

General Rules

1. For an atom in its elemental form (Na , C , O_2 , Cl_2 , P_4 , etc.): O.N. = 0.
2. For a monatomic ion: O.N. = ion charge (with the sign *before* the numeral).
3. The sum of O.N. values for the atoms in a molecule or formula unit of a compound equals zero. The sum of O.N. values for the atoms in a polyatomic ion equals the ion's charge.

Rules for Specific Atoms or Periodic Table Groups

- | | |
|------------------|---|
| 1. For Group 1: | O.N. = +1 in all compounds |
| 2. For Group 2: | O.N. = +2 in all compounds |
| 3. For hydrogen: | O.N. = +1 in combination with nonmetals
O.N. = -1 in combination with metals and boron (e.g., NaH) |
| 4. For fluorine: | O.N. = -1 in all compounds |
| 5. For oxygen: | O.N. = -1 in peroxides (e.g., H_2O_2)
O.N. = -2 in all other compounds (except with F) |
| 6. For Group 17: | O.N. = -1 in combination with metals, nonmetals (except O),
and other halogens lower in the group |

SAMPLE PROBLEM 4.15 | Determining the Oxidation Number of Each Element in a Compound (or Ion)

Problem Determine the oxidation number (O.N.) of each element in these species:
(a) Zinc chloride (b) Sulfur trioxide (c) Nitric acid (d) Dichromate ion

Plan We determine the formulas and consult Table 4.6, noting the general rules that the O.N. values for a compound add up to zero and those for a polyatomic ion add up to the ion's charge.

Solution (a) ZnCl_2 . The O.N. of each chloride ion is -1 (rule 6 in Table 4.6), for a total of -2, so the O.N. of Zn must be +2, since the sum of O.N.s must equal zero for a compound.

(b) SO_3 . The O.N. of each oxygen is -2 (rule 5 in Table 4.6), for a total of -6 . The O.N.s must add up to zero, so the O.N. of S is $+6$.

(c) HNO_3 . The O.N. of H is $+1$ (rule 3 in Table 4.6) and the O.N. of each O is -2 (rule 5 in Table 4.5), for a total of -6 . Therefore, the O.N. of N is $+5$.

(d) $\text{Cr}_2\text{O}_7^{2-}$. The sum of the O.N. values in a polyatomic ion equals the ion's charge. The O.N. of each O is -2 (rule 5 in Table 4.6), so the total for seven O atoms is -14 . Therefore, each Cr must have an O.N. of $+6$ in order for the sum of the O.N.s to equal the charge of the ion:

FOLLOW-UP PROBLEMS

4.15A Determine the O.N. of each element in the following:

- | | |
|--|---|
| (a) Scandium oxide (Sc_2O_3) | (b) Gallium(III) chloride (GaCl_3) |
| (c) Hydrogen phosphate ion | (d) Iodine trifluoride |

4.15B Determine the O.N. of each element in the following:

- | | |
|---|--------------------------|
| (a) Potassium carbonate | (b) Ammonium ion |
| (c) Calcium phosphide (Ca_3P_2) | (d) Sulfur tetrachloride |

SOME SIMILAR PROBLEMS 4.84–4.91

Using O.N.s to Identify Redox Reactions and Oxidizing and Reducing Agents A redox reaction is defined as one in which the oxidation numbers of the species change. By assigning an oxidation number to each atom, we can see which species was oxidized and which reduced and, thus, which is the oxidizing agent and which the reducing agent:

- If an atom has a higher (more positive or less negative) O.N. in the product than it had in the reactant, the reactant that contains that atom was oxidized (lost electrons) and is the reducing agent. Thus, *oxidation is shown by an increase in O.N.*
- If an atom has a lower (more negative or less positive) O.N. in the product than it had in the reactant, the reactant that contains that atom was reduced (gained electrons) and is the oxidizing agent. Thus, *reduction is shown by a decrease in O.N.*

Sample Problem 4.16 introduces the *tie-line*, a useful device for keeping track of changes in oxidation numbers.

SAMPLE PROBLEM 4.16

Identifying Redox Reactions and Oxidizing and Reducing Agents

Problem Use oxidation numbers to decide which of the following are redox reactions. For each redox reaction, identify the oxidizing agent and the reducing agent:

- (a) $2\text{Al}(s) + 3\text{H}_2\text{SO}_4(aq) \longrightarrow \text{Al}_2(\text{SO}_4)_3(aq) + 3\text{H}_2(g)$
 (b) $\text{H}_2\text{SO}_4(aq) + 2\text{NaOH}(aq) \longrightarrow \text{Na}_2\text{SO}_4(aq) + 2\text{H}_2\text{O}(l)$
 (c) $\text{PbO}(s) + \text{CO}(g) \longrightarrow \text{Pb}(s) + \text{CO}_2(g)$

Student Hot Spot

Student data indicate that you may struggle with identifying the reducing and oxidizing agents in a redox reaction. Access the eBook to view an additional Learning Resource video on this topic.

PLAN To determine whether a reaction is an oxidation-reduction process, we use Table 4.6 to assign each atom an O.N. and then note whether it changes as the reactants become products. If the O.N. of an atom changes during the reaction, we draw a tie-line from the atom on the left side to the same atom on the right side and label the change. For those reactions that are redox reactions, a reactant is the reducing agent if it contains an atom that is oxidized (O.N. *increases* from left to right in the equation). A reactant is the oxidizing agent if it contains an atom that is reduced (O.N. *decreases*). Note that products are never oxidizing or reducing agents.

Solution (a) Assigning oxidation numbers and marking the changes:

In this case, the O.N.s of Al and H change, so **this is a redox reaction**. The O.N. of Al changes from 0 to +3 (Al loses electrons), so Al is oxidized; Al is the reducing agent. The O.N. of H decreases from +1 to 0 (H gains electrons), so H^+ is reduced; H_2SO_4 is the oxidizing agent.

(b) Assigning oxidation numbers:

Because each atom in the products has the same O.N. that it had in the reactants, we conclude that **this is not a redox reaction**.

(c) Assigning oxidation numbers and marking the changes:

In this case, the O.N.s of Pb and C change, so **this is a redox reaction**. The O.N. of Pb decreases from +2 to 0, so Pb is reduced; PbO is the oxidizing agent. The O.N. of C increases from +2 to +4, so CO is oxidized; CO is the reducing agent.

In general, when a substance (such as CO) changes to one with more O atoms (such as CO_2), it is oxidized; and when a substance (such as PbO) changes to one with fewer O atoms (such as Pb), it is reduced.

Comment The reaction in part (b) is an acid-base reaction in which H_2SO_4 transfers two H^+ ions to two OH^- ions to form two H_2O molecules. In the net ionic equation,

we see that the O.N.s remain the same on both sides. Therefore, *an acid-base reaction is not a redox reaction*.

FOLLOW-UP PROBLEMS

4.16A Use oxidation numbers to decide which of the following are redox reactions. For all redox reactions, identify the oxidizing agent and the reducing agent:

- (a) $\text{NCl}_3(l) + 3\text{H}_2\text{O}(l) \longrightarrow \text{NH}_3(aq) + 3\text{HOCl}(aq)$
 (b) $\text{AgNO}_3(aq) + \text{NH}_4\text{I}(aq) \longrightarrow \text{AgI}(s) + \text{NH}_4\text{NO}_3(aq)$
 (c) $2\text{H}_2\text{S}(g) + 3\text{O}_2(g) \longrightarrow 2\text{SO}_2(g) + 2\text{H}_2\text{O}(g)$

4.16B Use oxidation numbers to decide which of the following are redox reactions. For all redox reactions, identify the oxidizing agent and the reducing agent:

- (a) $\text{SiO}_2(s) + 4\text{HF}(g) \longrightarrow \text{SiF}_4(g) + 2\text{H}_2\text{O}(l)$
 (b) $2\text{C}_2\text{H}_6(g) + 7\text{O}_2(g) \longrightarrow 4\text{CO}_2(g) + 6\text{H}_2\text{O}(g)$
 (c) $5\text{CO}(g) + \text{I}_2\text{O}_5(s) \longrightarrow 5\text{CO}_2(g) + \text{I}_2(s)$

SOME SIMILAR PROBLEMS 4.92–4.95

Figure 4.16 A summary of terminology for redox reactions.

Be sure to remember that *transferred electrons are never free because the reducing agent loses electrons and the oxidizing agent gains them simultaneously*. In other words, a complete reaction *cannot* be “an oxidation” or “a reduction”; it must be an oxidation-reduction. Figure 4.16 summarizes redox terminology.

Stoichiometry of Redox Reactions: Redox Titrations

Just as for precipitation and acid-base reactions, stoichiometry is important for redox reactions; a special application of stoichiometry that we focus on here is redox titration. In an acid-base titration, a known concentration of a base is used to find an unknown concentration of an acid (or vice versa). Similarly, in a redox titration, a known concentration of oxidizing agent is used to find an unknown concentration of reducing agent (or vice versa). This kind of titration has many applications, from measuring the iron content in drinking water to quantifying vitamin C in fruits and vegetables.

The permanganate ion, MnO_4^- , is a common oxidizing agent because it is deep purple and, so, serves as an indicator. In Figure 4.17, MnO_4^- is used to determine oxalate ion ($\text{C}_2\text{O}_4^{2-}$) concentration. As long as $\text{C}_2\text{O}_4^{2-}$ is present, it reduces the added MnO_4^- to faint pink (nearly colorless) Mn^{2+} (see Figure 4.17, *left*). When all the $\text{C}_2\text{O}_4^{2-}$ has been oxidized, the next drop of MnO_4^- turns the solution light purple (see Figure 4.17, *right*). This color change indicates the *end point*, which we assume is the same as the *equivalence point*, the point at which the electrons lost by the oxidized species ($\text{C}_2\text{O}_4^{2-}$) equal the electrons gained by the reduced species (MnO_4^-). We can calculate the $\text{C}_2\text{O}_4^{2-}$ concentration from the known volume of $\text{Na}_2\text{C}_2\text{O}_4$ solution and the known volume and concentration of KMnO_4 solution.

SAMPLE PROBLEM 4.17

Finding the Amount of Reducing Agent by Titration

Problem Calcium ion (Ca^{2+}) is necessary for the clotting of blood and many other physiological processes. To measure the Ca^{2+} concentration in 1.00 mL of human blood, $\text{Na}_2\text{C}_2\text{O}_4$ solution is added, which precipitates the Ca^{2+} as CaC_2O_4 . This solid is

dissolved in dilute H_2SO_4 to release $\text{C}_2\text{O}_4^{2-}$, and 2.05 mL of $4.88 \times 10^{-4} \text{ M}$ KMnO_4 is required to reach the end point. The balanced equation is

Calculate the amount (mol) of Ca^{2+} in 1.00 mL of blood.

Plan We have to find the amount (mol) of Ca^{2+} from the volume (2.05 mL) and concentration ($4.88 \times 10^{-4} \text{ M}$) of KMnO_4 used to oxidize the CaC_2O_4 precipitated from 1.00 mL of blood. We find the amount (mol) of KMnO_4 needed to reach the end point and use the molar ratio to find the amount (mol) of CaC_2O_4 . Then we use the chemical formula, which shows 1 mol of Ca^{2+} for every mol of CaC_2O_4 (see the road map).

Solution Converting volume (mL) and concentration (M) to amount (mol) of KMnO_4 :

$$\begin{aligned}\text{Amount (mol) of KMnO}_4 &= 2.05 \text{ mL soln} \times \frac{1 \text{ L}}{1000 \text{ mL}} \times \frac{4.88 \times 10^{-4} \text{ mol KMnO}_4}{1 \text{ L soln}} \\ &= 1.00 \times 10^{-6} \text{ mol KMnO}_4\end{aligned}$$

Using the molar ratio to convert amount (mol) of KMnO_4 to amount (mol) of CaC_2O_4 :

$$\begin{aligned}\text{Amount (mol) of CaC}_2\text{O}_4 &= 1.00 \times 10^{-6} \text{ mol KMnO}_4 \times \frac{5 \text{ mol CaC}_2\text{O}_4}{2 \text{ mol KMnO}_4} \\ &= 2.50 \times 10^{-6} \text{ mol CaC}_2\text{O}_4\end{aligned}$$

Finding the amount (mol) of Ca^{2+} :

$$\text{Amount (mol) of Ca}^{2+} = 2.50 \times 10^{-6} \text{ mol CaC}_2\text{O}_4 \times \frac{1 \text{ mol Ca}^{2+}}{1 \text{ mol CaC}_2\text{O}_4} = 2.50 \times 10^{-6} \text{ mol Ca}^{2+}$$

Check A very small volume of dilute KMnO_4 is needed, so 10^{-6} mol of KMnO_4 seems reasonable. The molar ratio of CaC_2O_4 to KMnO_4 is 5/2, which gives 2.5×10^{-6} mol of CaC_2O_4 and thus 2.5×10^{-6} mol of Ca^{2+} .

Comment 1. When blood is donated, the receiving bag contains $\text{Na}_2\text{C}_2\text{O}_4$ solution, which precipitates the Ca^{2+} ion to prevent clotting.

2. Normal Ca^{2+} concentration in human adult blood is 9.0–11.5 mg Ca^{2+} /100 mL. If we multiply the amount of Ca^{2+} in 1 mL by 100 and then multiply by the molar mass of Ca (40.08 g/mol), we get 1.0×10^{-2} g, or 10.0 mg Ca^{2+} in 100 mL:

$$\begin{aligned}\text{Mass (mg) of Ca}^{2+} &= \frac{2.50 \times 10^{-6} \text{ mol Ca}^{2+}}{1 \text{ mL}} \times 100 \text{ mL} \times \frac{40.08 \text{ g Ca}^{2+}}{1 \text{ mol Ca}^{2+}} \times \frac{1000 \text{ mg}}{1 \text{ g}} \\ &= 10.0 \text{ mg Ca}^{2+}\end{aligned}$$

FOLLOW-UP PROBLEMS

4.17A When 2.50 mL of low-fat milk is treated with $\text{Na}_2\text{C}_2\text{O}_4$ and the precipitate dissolved in H_2SO_4 , 6.53 mL of $4.56 \times 10^{-3} \text{ M}$ KMnO_4 is required to reach the end point. (a) Calculate the molarity of Ca^{2+} in the milk sample. (b) What is the concentration of Ca^{2+} in g/L? Is this value consistent with the typical value for milk of about 1.2 g Ca^{2+} /L?

4.17B The amount of iron in an iron ore is determined by converting the Fe to FeSO_4 , followed by titration with a solution of $\text{K}_2\text{Cr}_2\text{O}_7$. The balanced equation is

(a) What is the molarity of Fe^{2+} if 21.85 mL of 0.250 M $\text{K}_2\text{Cr}_2\text{O}_7$ is required for the titration of 30.0 mL of FeSO_4 solution? (b) If the original sample of iron ore had a mass of 2.58 g, what is the mass percent of iron in the ore?

4.5 ELEMENTS IN REDOX REACTIONS

In many redox reactions, such as those in parts (a) and (c) of Sample Problem 4.16, *atoms occur as an element on one side of an equation and as part of a compound on the other*.* One way to classify these reactions is by comparing the *numbers* of reactants and products. With that approach, we have three types—*combination*, *decomposition*, and *displacement*; one other type involving elements is *combustion*. In this section, we survey each type and consider several examples.

Combination Redox Reactions

In a *combination redox reaction*, two or more reactants, at least one of which is an element, form a compound:

Combining Two Elements Two elements may react to form binary ionic or covalent compounds. The following are some important examples.

1. *Metal and nonmetal form an ionic compound.* Figure 4.18 shows a typical example of a combination redox reaction, between the alkali metal potassium and the halogen chlorine, on the macroscopic, atomic, and symbolic levels. Note the change in oxidation numbers in the balanced equation: K is oxidized, so it is the reducing agent; Cl₂ is reduced, so it is the oxidizing agent. In fact, whenever a binary ionic compound forms from its elements, *the metal is the reducing agent and the nonmetal is the oxidizing agent*.

In another example of metal reacting with nonmetal, aluminum reacts with O₂, as does nearly every metal, to form an ionic oxide:

The Al₂O₃ layer on the surface of an aluminum pot prevents oxygen from reacting with the next layer of Al atoms, thus protecting the metal from further oxidation.

2. *Two nonmetals form a covalent compound.* In one of thousands of examples, ammonia forms from nitrogen and hydrogen in a reaction that occurs in industry on an enormous scale; N₂ is reduced and thus is the oxidizing agent, while H₂ is oxidized and is the reducing agent:

Halogens react with many other nonmetals, as in the formation of phosphorus trichloride, a reactant in the production of pesticides and other organic compounds:

*Many other redox reactions, however, do not involve elements (see Sample Problem 4.17).

Figure 4.18 Combining elements to form an ionic compound: potassium metal and chlorine gas form solid potassium chloride. Darker atoms in the atomic view indicate the stoichiometry.

Source: Stephen Frisch/McGraw Hill

Nearly every nonmetal reacts with O_2 to form a covalent oxide, as when nitrogen monoxide forms from the nitrogen and oxygen in air at the very high temperatures created by lightning and in a car's engine:

Combining a Compound and an Element Many binary covalent compounds react with nonmetals to form larger compounds. Many nonmetal oxides react with additional O_2 to form “higher” oxides (those with more O atoms in each molecule). For example,

Similarly, many nonmetal halides combine with additional halogen to form “higher” halides:

Decomposition Redox Reactions

In a *decomposition redox reaction*, a compound forms two or more products, at least one of which is an element:

In any decomposition reaction, the reactant absorbs enough energy for one or more bonds to break. The energy can take several forms, but the most important are decomposition by heat (thermal) and by electricity (electrolytic). The products are either elements or elements and smaller compounds.

Thermal Decomposition When the energy absorbed is heat, the reaction is called a *thermal decomposition*. (A Greek delta, Δ , above the yield arrow indicates strong heating is required for the reaction to occur.) Many metal oxides, chlorates, and perchlorates release oxygen when strongly heated. Heating potassium chlorate is a method for forming small amounts of oxygen in the laboratory; the same reaction occurs in some explosives and fireworks. In this reaction, Cl in potassium chlorate is reduced, while oxygen in the reactant is oxidized to elemental O_2 :

The decomposition of mercury(II) oxide is shown in Figure 4.19. Notice that, in these thermal decomposition reactions, the lone reactant is the oxidizing *and* the reducing agent. For example, in the reactant HgO , the O^{2-} ion reduces the Hg^{2+} ion and, at the same time, Hg^{2+} oxidizes O^{2-} .

Electrolytic Decomposition In the process of electrolysis, a compound absorbs electrical energy and decomposes into its elements. In the early 19th century, the observation of the electrolysis of water was crucial for establishing atomic masses:

Figure 4.19 Decomposition of the compound mercury(II) oxide to its elements.

Source: Stephen Frisch/McGraw Hill

Many active metals, such as sodium, magnesium, and calcium, are produced industrially by electrolysis of their molten halides:

(We examine the details of electrolysis in Chapter 21 and its role in the industrial recovery of several elements in Chapter 22.)

Displacement Redox Reactions and Activity Series

In any *displacement reaction*, the number of substances on the two sides of the equation remains the same, but atoms (or ions) exchange places. There are two types of displacement reactions:

1. In *double-displacement* (metathesis) reactions, such as precipitation and acid-base reactions (Sections 4.2 and 4.3), atoms (or ions) of two *compounds* exchange places; these reactions are *not* redox processes:

2. In *single-displacement* reactions, one of the substances is an *element*; therefore, *all single-displacement reactions are redox processes*:

In solution, single-displacement reactions occur when an atom of one element displaces the ion of another: if the displacement involves metals, the atom *reduces* the ion; if it involves nonmetals (specifically halogens), the atom *oxidizes* the ion. In two *activity series*—one for metals and one for halogens—the elements are ranked in order of their ability to displace hydrogen (for metals) and one another.

The Activity Series of the Metals Metals are ranked by their ability to displace H_2 from various sources and another metal from solution. In all displacements of H_2 , the metal is the reducing agent (O.N. increases), and water or acid is the oxidizing agent (O.N. of H decreases). The activity series of the metals is based on these facts:

- *The most reactive metals displace H_2 from liquid water.* Group 1 metals and Ca, Sr, and Ba from Group 2 displace H_2 from water (Figure 4.20).
- *Slightly less reactive metals displace H_2 from steam.* Heat supplied by steam is needed for less reactive metals, such as Al and Zn, to displace H_2 :

- *Still less reactive metals displace H_2 from acids.* The higher concentration of H^+ in acid solutions is needed for even less reactive metals, such as Ni and Sn, to displace H_2 (Figure 4.21). For nickel, the net ionic equation is

- *The least reactive metals cannot displace H_2 from any source.* Fortunately, precious metals, such as silver, gold, and platinum, do *not* react with water or acid.

Figure 4.20 The active metal lithium displaces hydrogen from water. Only water molecules involved in the reaction are red and white.

Source: Stephen Frisch/McGraw Hill

Figure 4.21 The displacement of H_2 from acid by nickel.

Source: Stephen Frisch/McGraw Hill

- An atom of one metal displaces the ion of another. Comparisons of metal reactivity show, for example, that Zn metal displaces Cu^{2+} ion from aqueous CuSO_4 :

And Figure 4.22 shows that Cu metal displaces silver (Ag^+) ion from solution; therefore, zinc is more reactive than copper, which is more reactive than silver.

Many such reactions form the basis of the **activity series of the metals**. Note these two points from Figure 4.23:

- Elements higher on the list are stronger reducing agents than elements lower down; in other words, any metal can reduce, or displace, the ions of metals below it. For example, since Mn is higher in the list than Ni, $\text{Mn}(s)$ can reduce Ni^{2+} ions, displacing them from solution:

but $\text{Ni}(s)$ cannot reduce Mn^{2+} ions:

- From higher to lower, a metal can displace H_2 (reduce H^+) from water, steam, acid, or not at all.

The Activity Series of the Halogens Reactivity of the elements increases up Group 17, so we have

A halogen higher in the group is a stronger oxidizing agent than one lower down (Figure 4.24). Thus, elemental chlorine can oxidize bromide ions (*below*) or iodide ions from solution, and elemental bromine can oxidize iodide ions:

Figure 4.22 A more reactive metal (Cu) displacing the ion of a less reactive metal (Ag^+) from solution.

- Cl_2 can oxidize Br^- and I^- .
- Br_2 can oxidize only I^- .
- I_2 is the least reactive halogen and cannot oxidize any halide ions above it.

Figure 4.24 Reactivity of the halogens.

Combustion Reactions

Combustion is the process of combining with oxygen, most commonly with the release of heat and the production of light, as in a flame. Combustion reactions are not usually classified by the number of reactants and products, but *all of these*

reactions are redox processes because elemental oxygen is a reactant and functions as an oxidizing agent:

The combustion reactions that we commonly use to produce energy involve coal, petroleum, gasoline, natural gas, or wood as a reactant. These mixtures consist of substances with many C—C and C—H bonds, which break during the reaction, and each C and H atom combines with oxygen to form CO₂ and H₂O. The combustion of butane is typical:

Biological *respiration* is a multistep combustion process that occurs within our cells when we “burn” foodstuffs, such as glucose, for energy:

Table 4.7 summarizes the types of redox reactions discussed in this section.

SAMPLE PROBLEM 4.18 | Identifying the Type of Redox Reaction

Problem Classify each of these redox reactions as a combination, decomposition, or displacement reaction; write a balanced molecular equation for each, as well as total and net ionic equations for part (c); and identify the oxidizing and reducing agents:

- (a) Magnesium(s) + nitrogen(g) $\longrightarrow$ magnesium nitride(s)
 (b) Hydrogen peroxide(l) $\longrightarrow$ water + oxygen gas
 (c) Aluminum(s) + lead(II) nitrate(aq) $\longrightarrow$ aluminum nitrate(aq) + lead(s)

Plan To decide on reaction type, recall that combination reactions have fewer products than reactants, decomposition reactions have more products than reactants, and displacement reactions have the same number of reactants and products. The oxidation number (O.N.) becomes more positive for the reducing agent and less positive for the oxidizing agent.

Solution (a) **Combination:** two substances form one. This reaction occurs, along with formation of magnesium oxide, when magnesium burns in air, which is mostly N₂:

Mg is the reducing agent; N₂ is the oxidizing agent.

$$\begin{array}{c} \text{+1} \quad \text{-1} \\ | \quad | \\ 2\text{H}_2\text{O}_2(l) \end{array} \longrightarrow \begin{array}{c} \text{+1} \quad \text{-2} \\ | \quad | \\ 2\text{H}_2\text{O}(l) \end{array} + \begin{array}{c} 0 \\ | \\ \text{O}_2(g) \end{array}$$
$$2\overset{0}{\text{Al}}(\text{s}) + 3\overset{+2}{\text{Pb}}\overset{+5}{\text{(NO}_3)_2}(\text{aq}) \longrightarrow 2\overset{+3}{\text{Al}}\overset{+5}{\text{(NO}_3)_3}(\text{aq}) + 3\overset{0}{\text{Pb}}(\text{s})$$
$$2\text{Al}(s) + 3\text{Pb}^{2+}(aq) \longrightarrow 2\text{Al}^{3+}(aq) + 3\text{Pb}(s)$$

4.6 THE REVERSIBILITY OF REACTIONS AND THE EQUILIBRIUM STATE

So far, we have viewed reactions as transformations of reactants into products that proceed until completion, that is, until the limiting reactant is used up. However, many reactions stop before this happens because two opposing reactions are taking place simultaneously: the forward (left-to-right) reaction continues, but the reverse (right-to-left) reaction occurs just as fast (at the same rate). At this point, *no further changes appear in the amounts of reactants or products*, and the reaction mixture has reached **dynamic equilibrium**. On the macroscopic level, the reaction is *static*, but it is *dynamic* on the molecular level.

Reversibility of Calcium Carbonate Decomposition In principle, *every reaction is reversible and will reach dynamic equilibrium if all the reactants and products are present*. Consider the reversible breakdown and formation of calcium carbonate. When heated, this compound decomposes to calcium oxide and carbon dioxide:

And it forms when calcium oxide and carbon dioxide react:

Let's study this process with two experiments:

1. We place CaCO_3 in an *open* steel container and heat it to approximately 900°C (Figure 4.25A). The CaCO_3 starts decomposing to CaO and CO_2 , and the CO_2 escapes from the open container. The reaction goes to completion because the reverse reaction (formation) cannot occur in the absence of CO_2 .
2. We perform the same experiment in a *closed* container from which the CO_2 produced cannot escape (Figure 4.25B). The decomposition (forward reaction) starts as before, but soon the CaO and CO_2 start reacting with each other (formation).

Figure 4.25 The equilibrium state.

Gradually, with time, as the amounts of CaO and CO₂ increase, the formation reaction speeds up. Eventually, the reverse reaction (formation) occurs as fast as the forward reaction (decomposition), and the amounts of CaCO₃, CaO, and CO₂ no longer change: the system has reached a state of equilibrium. We indicate this condition with a pair of arrows pointing in opposite directions:

In contrast to the reaction in the open container, equilibrium *is* reached because *all the substances remain in contact with each other*.

Some Other Types of Reversible Reactions Reaction reversibility applies to other systems as well:

1. *Weak acids in water.* Weak acids dissociate very little into ions in water because the dissociation becomes balanced by a reassociation of H₃O⁺ with the anion to re-form the weak acid and water. For example, when acetic acid dissolves, some CH₃COOH molecules transfer a proton to H₂O and form H₃O⁺ and CH₃COO[−] ions. As more ions form, the ions react with each other more often to re-form acetic acid and water:

In fact, in 0.1 M CH₃COOH at 25°C, only about 1.3% of acid molecules are dissociated! Each weak acid dissociates to its own extent. For example, under the same conditions, propionic acid (CH₃CH₂COOH) is 1.1% dissociated, and hydrofluoric acid (HF) is 8.6% dissociated.

2. *Weak bases in water.* Similarly, the weak base ammonia reacts with water to form NH₄⁺ and OH[−] ions. As more ions form, they interact more often to re-form ammonia and water, and the rates of the forward and reverse reactions soon balance:

The weak base methylamine (CH₃NH₂) reacts with water to a greater extent than ammonia does before reaching equilibrium, and the weak base aniline (C₆H₅NH₂) reacts to a lesser extent.

3. *Gas-forming reactions.* Acids react with carbonates (see the subsection Gas-Forming Reactions in Section 4.3):

This type of reaction goes to completion in an open container because the CO₂ escapes. But, if the container is closed to keep the CO₂ present, the reverse reaction takes place and the mixture reaches equilibrium.

4. *Other acid-base and precipitation reactions.* These processes seem to “go to completion” because the ions become tied up in the product, either as water (acid-base) or as an insoluble solid (precipitation), and are not available to re-form reactants. In truth, though, water and ionic precipitates do dissociate to an extremely small extent, so these reactions also reach equilibrium, but the final reaction mixture consists of *almost* all product.

Thus, some reactions proceed very little, producing very little product before reaching equilibrium; others proceed almost to completion, with almost all reactants depleted; and still others reach equilibrium with significant amounts of both reactants *and* products present. In Chapter 20, we’ll examine the factors that determine to what extent a reaction proceeds.

Dynamic equilibrium occurs in many natural systems, from the cycling of water in the environment to the nuclear processes occurring in stars. We examine equilibrium in chemical and physical systems in Chapters 12, 13, and 17 through 21.

› Summary of Section 4.6

- › Every reaction is reversible if all the substances involved are present.
- › As the amounts of products increase, the reactants begin to re-form. When the reverse reaction occurs as rapidly as the forward reaction, the amounts of the substances no longer change, and the reaction mixture has reached dynamic equilibrium.

- › Weak acids and bases reach equilibrium in water with a very small proportion of their molecules dissociated.
- › An aqueous ionic reaction “goes to completion” because a product is removed (as a gas) or because a product (usually water or a precipitate) is formed that reacts very slightly in a reverse reaction.

CHAPTER REVIEW GUIDE

Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

Understand These Concepts

1. The meanings of *concentration* and *molarity* (§4.1)
2. The effect of dilution on the concentration of a solute (§4.1)
3. Why water is a polar molecule and how it dissociates ionic compounds into ions (§4.1)
4. The differing nature of the species present when ionic and covalent compounds dissolve in water (§4.1)
5. The distinctions among strong electrolytes, weak electrolytes, and nonelectrolytes (§4.1, §4.3)
6. The three types of equations that specify the species and the chemical change in an aqueous ionic reaction (§4.2)
7. The key event in three classes of aqueous ionic reactions (§4.2–§4.4)
8. How to decide whether a precipitation reaction occurs (§4.2)
9. The distinction between strong and weak aqueous acids and bases (§4.3)
10. How some types of substances react with acids or bases in gas-forming reactions (§4.3)
11. The distinction between a transfer and a shift of electrons in the formation of ionic and covalent compounds (§4.4)
12. The relation between changes in oxidation number and identities of oxidizing and reducing agents (§4.4)
13. The presence of elements in combination, decomposition, and displacement redox reactions; the meaning of an activity series (§4.5)
14. The balance between forward and reverse reactions in dynamic equilibrium; why some acids and bases are weak (§4.6)

Master These Skills

1. Calculating molarity or mass of a solute in solution (SPs 4.1, 4.2)
2. Preparing a dilute solution from a concentrated one (SP 4.3)
3. Using molecular scenes to visualize changes in concentration (SP 4.4)
4. Using molecular scenes to depict an ionic compound in aqueous solution (SP 4.5)
5. Using the formula of a compound to find the number of moles of ions in solution (SP 4.6)
6. Predicting whether a precipitation reaction occurs (SP 4.7)
7. Using molecular scenes to understand precipitation reactions (SP 4.8)
8. Using molar ratios to convert between amounts of reactants and products for reactions in solution (SPs 4.9, 4.10, 4.13)
9. Determining the number of H^+ (or OH^-) ions in an aqueous acid (or base) solution (SP 4.11)
10. Writing ionic equations to describe precipitation and acid-base reactions (SPs 4.7, 4.8, 4.12)
11. Calculating an unknown concentration from an acid-base or redox titration (SPs 4.14, 4.17)
12. Determining the oxidation number of any element in a compound or an ion (SP 4.15)
13. Identifying redox reactions and oxidizing and reducing agents from changes in O.N.s (SP 4.16)
14. Distinguishing among combination, decomposition, and displacement redox reactions (SP 4.18)

Key Terms

Page numbers appear in parentheses.

acid (161)	electrolyte (148)	oxidation (170)	reduction (170)
acid-base (neutralization) reaction (160)	end point (168)	oxidation number (O.N.) (171)	salt (163)
activity series of the metals (180)	equivalence point (168)	oxidation-reduction (redox) reaction (169)	solute (141)
aqueous solution (141)	hydronium ion (161)	oxidizing agent (170)	solution (141)
base (161)	metathesis reaction (155)	polar molecule (147)	solvated (147)
concentration (141)	molarity (<i>M</i>) (142)	precipitate (152)	solvent (141)
dynamic equilibrium (184)	molecular equation (153)	precipitation reaction (152)	spectator ion (153)
	net ionic equation (153)	reducing agent (170)	titration (167)
	nonelectrolyte (151)		total ionic equation (153)

Key Equations and Relationships

Page numbers appear in parentheses.

4.1 Defining molarity (142):

$$\text{Molarity} = \frac{\text{moles of solute}}{\text{liters of solution}} \quad \text{or} \quad M = \frac{\text{mol solute}}{\text{L soln}}$$

4.2 Diluting a concentrated solution (145):

$$M_{\text{dil}} \times V_{\text{dil}} = \text{amount (mol) of solute} = M_{\text{conc}} \times V_{\text{conc}}$$

CHAPTER PRACTICE TEST

The answers to the Practice Test problems are shown below and the full solutions can be found in the e-book.

1. 9.82 g of KOH is dissolved in 1.00 L of water. Then 25.0 mL of this solution is diluted with water to a final volume of 750.0 mL. What is the final molarity of the 750.0 mL KOH solution?

- (a) 0.00583 *M* (b) 0.0163 *M* (c) 0.0333 *M*
(d) 0.229 *M* (e) 0.321 *M*

2. Solutions of BaCl₂, NiSO₄ and KNO₃ are mixed together. What is the likely precipitate?

- (a) Ni(NO₃)₂ (b) Ba(NO₃)₂ (c) BaSO₄
(d) KCl (e) K₂SO₄ (f) NiCl₂

3. What mass of precipitate is formed when 47.8 mL of 0.334 *M* NaF is reacted with an excess of aqueous Ca(NO₃)₂?

- (a) 1.25 g (b) 0.472 g (c) 2.49 g
(d) 0.943 g (e) 0.623 g

4. What are the spectator ions in the reaction between aqueous solutions of magnesium sulfide and iron(II) sulfate?

- (a) Mg²⁺, SO₄²⁻ (b) Mg²⁺, S²⁻
(c) Fe²⁺, SO₄²⁻ (d) Fe²⁺, S²⁻

5. Identify the reducing agent in the following oxidation-reduction reaction:

- (a) SO₂ (b) HNO₃ (c) H₂O
(d) H₂SO₄ (e) NO

6. Calculate the molarity of a KOH solution if 35.55 mL of the solution is required to completely titrate 28.75 mL of 0.985 *M* H₃PO₄.

- (a) 0.266 *M* (b) 2.39 *M* (c) 0.797 *M*
(d) 3.65 *M* (e) 3.02 *M* (f) 1.32 *M*

7. In which of the following species does the sulfur atom have the highest oxidation number?

- (a) H₂S (b) S₈ (c) H₂SO₄
(d) SO₂ (e) Na₂S₂O₃

8. If 4.39 g AlCl₃ is dissolved in enough water to make exactly 100.0 mL of solution, what is the molar concentration of chloride ion?

- (a) 0.0234 *M* (b) 0.0934 *M* (c) 0.329 *M*
(d) 0.132 *M* (e) 0.988 *M*

9. Choose the **two** strong electrolytes from the following list of aqueous solutions. Select **both** correct answers.

- (a) HNO₃ (b) CH₃OH (c) HF
(d) CaBr₂ (e) NH₃ (f) C₆H₁₂O₆

10. What are the spectator ions in the reaction between nitrous acid and sodium hydroxide?

- (a) Na⁺, OH⁻, H⁺, and NO₂⁻ (b) H⁺ and OH⁻
(c) Na⁺ and NO₂⁻ (d) H⁺ and NO₂⁻
(e) Na⁺ and OH⁻ (f) Na⁺

Answers: 1. a; 2. c; 3. e; 4. a; 5. a; 6. b; 7. c; 8. e; 9. a, d; 10. f

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

4.1A Amount (mol) of KI = $6.97 \text{ g KI} \times \frac{1 \text{ mol KI}}{166.00 \text{ g KI}}$
= 0.0420 mol KI

$$M = \frac{0.0420 \text{ mol KI}}{100. \text{ mL soln}} \times \frac{1000 \text{ mL}}{1 \text{ L}} = 0.420 \text{ M}$$

4.1B Amount (mol) of NaNO₃ = $175 \text{ mg NaNO}_3 \times \frac{1 \text{ g}}{1000 \text{ mg}}$
 $\times \frac{1 \text{ mol NaNO}_3}{85.00 \text{ g NaNO}_3}$
= 2.06×10^{-3} mol NaNO₃

$$M = \frac{2.06 \times 10^{-3} \text{ mol NaNO}_3}{15.0 \text{ mL soln}} \times \frac{1000 \text{ mL}}{1 \text{ L}} = 0.137 \text{ M}$$

Volume (L) of sucrose soln

$$= 135 \text{ g sucrose} \times \frac{1 \text{ mol sucrose}}{342.30 \text{ g sucrose}} \times \frac{1 \text{ L soln}}{3.30 \text{ mol sucrose}}$$

$$= 0.120 \text{ L soln}$$

Amount (mol) of H₂SO₄

$$= 40.5 \text{ mL soln} \times \frac{1 \text{ L}}{1000 \text{ mL}} \times \frac{0.128 \text{ mol H}_2\text{SO}_4}{1 \text{ L soln}}$$

$$= 5.18 \times 10^{-3} \text{ mol H}_2\text{SO}_4$$

4.3A $V_{\text{dil}} = \frac{M_{\text{conc}} \times V_{\text{conc}}}{M_{\text{dil}}} = \frac{4.50 \text{ M} \times 60.0 \text{ mL}}{1.25 \text{ M}} = 216 \text{ mL}$

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS (continued)

$$\mathbf{4.3B} \quad M \text{ of diluted } \text{H}_2\text{SO}_4 = \frac{M_{\text{conc}} \times V_{\text{conc}}}{V_{\text{dil}}} = \frac{7.50 M \times 25.0 \text{ mL}}{500. \text{ mL}} \\ = 0.375 M \text{ H}_2\text{SO}_4$$

$$\text{Mass (g) of } \text{H}_2\text{SO}_4/\text{mL soln} = \frac{0.375 \text{ mol H}_2\text{SO}_4}{1 \text{ L soln}} \times \frac{1 \text{ L}}{1000 \text{ mL}} \\ \times \frac{98.08 \text{ g H}_2\text{SO}_4}{1 \text{ mol H}_2\text{SO}_4} \\ = 3.68 \times 10^{-2} \text{ g/mL soln}$$

4.4A To obtain B, the total volume of solution A was reduced by half:

$$V_{\text{conc}} = V_{\text{dil}} \times \frac{N_{\text{dil}}}{N_{\text{conc}}} = 1.0 \text{ mL} \times \frac{6 \text{ particles}}{12 \text{ particles}} = 0.50 \text{ mL}$$

To obtain C, $\frac{1}{2}$ of a unit volume of solvent was added to the unit volume of A:

$$V_{\text{dil}} = V_{\text{conc}} \times \frac{N_{\text{conc}}}{N_{\text{dil}}} = 1.0 \text{ mL} \times \frac{6 \text{ particles}}{4 \text{ particles}} = 1.5 \text{ mL}$$

$$\mathbf{4.4B} \quad N_{\text{dil}} = N_{\text{conc}} \times \frac{V_{\text{conc}}}{V_{\text{dil}}} = 12 \text{ particles} \times \frac{100. \text{ mL}}{400. \text{ mL}} \\ = 3 \text{ particles}$$

Circle B is the best representation of the unit volume.

4.5A (a) There are three $2+$ particles and twice as many $1-$ particles. The compound is BaCl_2 .

$$\text{(b) Mass (g) of } \text{BaCl}_2 = 9 \text{ particles} \times \frac{0.05 \text{ mol particles}}{1 \text{ particle}} \\ \times \frac{1 \text{ mol BaCl}_2}{3 \text{ mol particles}} \times \frac{208.23 \text{ g BaCl}_2}{1 \text{ mol BaCl}_2} \\ = 31.2 \text{ g BaCl}_2$$

$$\text{(b) Amount (mol) of ions} = 0.40 \text{ mol Na}_3\text{PO}_4 \times \frac{4 \text{ mol ions}}{1 \text{ mol Na}_3\text{PO}_4} \\ = 1.6 \text{ mol ions}$$

$$\text{(c) Mol of } \text{Na}^+ = 0.40 \text{ mol Na}_3\text{PO}_4 \times \frac{3 \text{ mol Na}^+}{1 \text{ mol Na}_3\text{PO}_4} = 1.2 \text{ mol Na}^+$$

$$M = \frac{1.2 \text{ mol Na}^+}{600. \text{ mL}} \times \frac{1000 \text{ mL}}{1 \text{ L}} = 2.0 M$$

Amount (mol) of Mg^{2+}

$$= 354 \text{ g Mg}(\text{C}_2\text{H}_3\text{O}_2)_2 \times \frac{1 \text{ mol Mg}(\text{C}_2\text{H}_3\text{O}_2)_2}{142.39 \text{ g Mg}(\text{C}_2\text{H}_3\text{O}_2)_2} \\ \times \frac{1 \text{ mol Mg}^{2+}}{1 \text{ mol Mg}(\text{C}_2\text{H}_3\text{O}_2)_2} \\ = 2.49 \text{ mol Mg}^{2+}$$

Amount (mol) of $\text{C}_2\text{H}_3\text{O}_2^-$

$$= 354 \text{ g Mg}(\text{C}_2\text{H}_3\text{O}_2)_2 \times \frac{1 \text{ mol Mg}(\text{C}_2\text{H}_3\text{O}_2)_2}{142.39 \text{ g Mg}(\text{C}_2\text{H}_3\text{O}_2)_2} \\ \times \frac{2 \text{ mol C}_2\text{H}_3\text{O}_2^-}{1 \text{ mol Mg}(\text{C}_2\text{H}_3\text{O}_2)_2} \\ = 4.97 \text{ mol C}_2\text{H}_3\text{O}_2^-$$

$$\text{Amount (mol) of } \text{NH}_4^+ = 125 \text{ mL} \times \frac{1 \text{ L}}{1000 \text{ mL}} \\ \times \frac{0.270 \text{ mol } (\text{NH}_4)_2\text{CrO}_4}{1 \text{ L}} \\ \times \frac{2 \text{ mol NH}_4^+}{1 \text{ mol } (\text{NH}_4)_2\text{CrO}_4} = 0.0675 \text{ mol NH}_4^+$$

$$\text{Amount (mol) of } \text{CrO}_4^{2-} = 125 \text{ mL} \times \frac{1 \text{ L}}{1000 \text{ mL}} \\ \times \frac{0.270 \text{ mol } (\text{NH}_4)_2\text{CrO}_4}{1 \text{ L}} \\ \times \frac{1 \text{ mol CrO}_4^{2-}}{1 \text{ mol } (\text{NH}_4)_2\text{CrO}_4} = 0.0338 \text{ mol CrO}_4^{2-}$$

$$\text{Amount (mol) of } \text{Al}^{3+} \\ = 112 \text{ g Al}_2(\text{SO}_4)_3 \times \frac{1 \text{ mol Al}_2(\text{SO}_4)_3}{342.14 \text{ g Al}_2(\text{SO}_4)_3}$$

$$\times \frac{2 \text{ mol Al}^{3+}}{1 \text{ mol Al}_2(\text{SO}_4)_3}$$

$$= 0.655 \text{ mol Al}^{3+}$$

Amount (mol) of SO_4^{2-}

$$= 112 \text{ g Al}_2(\text{SO}_4)_3 \times \frac{1 \text{ mol Al}_2(\text{SO}_4)_3}{342.14 \text{ g Al}_2(\text{SO}_4)_3}$$

$$\times \frac{3 \text{ mol SO}_4^{2-}}{1 \text{ mol Al}_2(\text{SO}_4)_3}$$

$$= 0.982 \text{ mol SO}_4^{2-}$$

$$\text{Amount (mol) of } \text{Al}^{3+} = 335 \text{ mL} \times \frac{1 \text{ L}}{1000 \text{ mL}} \\ \times \frac{1.60 \text{ mol Al}(\text{NO}_3)_3}{1 \text{ L}}$$

$$\times \frac{1 \text{ mol Al}^{3+}}{1 \text{ mol Al}(\text{NO}_3)_3} = 0.536 \text{ mol Al}^{3+}$$

$$\begin{aligned}\text{Amount (mol) of NO}_3^- &= 335 \text{ mL} \times \frac{1 \cancel{\text{L}}}{1000 \cancel{\text{mL}}} \\ &\times \frac{1.60 \text{ mol Al(NO}_3)_3}{1 \cancel{\text{L}}} \\ &\times \frac{3 \text{ mol NO}_3^-}{1 \text{ mol Al(NO}_3)_3} = 1.61 \text{ mol NO}_3^-\end{aligned}$$

(c) No reaction occurs.

(b) No reaction occurs.

4.8A (a) There are 2+ and 1- ions. PbCl_2 is insoluble, so beaker A contains a solution of $\text{Zn(NO}_3)_2$.

(b) There are 2+ and 1- ions. Cd(OH)_2 is insoluble, so beaker B contains a solution of Ba(OH)_2 .

(c) The precipitate is zinc hydroxide, and the spectator ions are Ba^{2+} and NO_3^- .

Total ionic:

(d) The OH^- ion is limiting.

$$\begin{aligned}\text{Mass (g) of Zn(OH)}_2 &= 6 \text{ OH}^- \text{ particles} \times \frac{0.050 \text{ mol OH}^- \text{ ions}}{1 \text{ OH}^- \text{ particle}} \\ &\times \frac{1 \text{ mol Zn(OH)}_2}{2 \text{ mol OH}^- \text{ ions}} \times \frac{99.40 \text{ g Zn(OH)}_2}{1 \text{ mol Zn(OH)}_2} \\ &= 15 \text{ g Zn(OH)}_2\end{aligned}$$

4.8B (a) There are 1+ and 2- ions. Ag_2SO_4 is insoluble, so beaker A contains a solution of Li_2CO_3 .

(b) There are 2+ and 1- ions. Ni(OH)_2 is insoluble, so beaker B contains a solution of CaCl_2 .

(c) The precipitate is CaCO_3 , and the spectator ions are Li^+ and Cl^- .

Molecular:

(d) The Ca^{2+} ion is limiting.

$$\begin{aligned}\text{Mass (g) of CaCO}_3 &= 3 \text{ Ca}^{2+} \text{ particles} \times \frac{0.20 \text{ mol Ca}^{2+} \text{ ions}}{1 \text{ Ca}^{2+} \text{ particle}} \\ &\times \frac{1 \text{ mol CaCO}_3}{1 \text{ mol Ca}^{2+} \text{ ions}} \times \frac{100.09 \text{ g CaCO}_3}{1 \text{ mol CaCO}_3} \\ &= 60. \text{ g CaCO}_3\end{aligned}$$

$$\begin{aligned}\text{Volume (L) of Na}_3\text{PO}_4 &= 0.300 \text{ L CaCl}_2 \text{ soln} \\ &\times \frac{0.175 \text{ mol CaCl}_2}{1 \text{ L CaCl}_2 \text{ soln}} \times \frac{2 \text{ mol Na}_3\text{PO}_4}{3 \text{ mol CaCl}_2} \\ &\times \frac{1 \text{ L Na}_3\text{PO}_4 \text{ solution}}{0.260 \text{ mol Na}_3\text{PO}_4} \\ &= 0.135 \text{ L soln}\end{aligned}$$

$$\begin{aligned}\text{Amount (mol) of AgNO}_3 &= 0.148 \text{ g AgCl} \times \frac{1 \text{ mol AgCl}}{143.32 \text{ g AgCl}} \\ &\times \frac{1 \text{ mol AgNO}_3}{1 \text{ mol AgCl}} \\ &= 0.00103 \text{ mol AgNO}_3\end{aligned}$$

$$\begin{aligned}\text{Molarity of AgNO}_3 &= \frac{0.00103 \text{ mol AgNO}_3}{45.0 \text{ mL}} \times \frac{10^3 \text{ mL}}{1 \text{ L}} \\ &= 0.0229 \text{ M}\end{aligned}$$

$$\begin{aligned}\text{For Pb(C}_2\text{H}_3\text{O}_2)_2: \text{Amount (mol) of Pb(C}_2\text{H}_3\text{O}_2)_2 &= 0.268 \cancel{\text{L}} \times \frac{1.50 \text{ mol Pb(C}_2\text{H}_3\text{O}_2)_2}{1 \cancel{\text{L}}} \\ &= 0.402 \text{ mol Pb(C}_2\text{H}_3\text{O}_2)_2\end{aligned}$$

$$\begin{aligned}\text{Amount (mol) of PbCl}_2 &= 0.402 \text{ mol Pb(C}_2\text{H}_3\text{O}_2)_2 \\ &\times \frac{1 \text{ mol PbCl}_2}{1 \text{ mol Pb(C}_2\text{H}_3\text{O}_2)_2} \\ &= 0.402 \text{ mol PbCl}_2\end{aligned}$$

$$\begin{aligned}\text{For NaCl: Amount (mol) of NaCl} &= 0.130 \cancel{\text{L}} \times \frac{3.40 \text{ mol NaCl}}{1 \cancel{\text{L}}} \\ &= 0.442 \text{ mol NaCl}\end{aligned}$$

$$\begin{aligned}\text{Amount (mol) of PbCl}_2 &= 0.442 \text{ mol NaCl} \times \frac{1 \text{ mol PbCl}_2}{2 \text{ mol NaCl}} \\ &= 0.221 \text{ mol PbCl}_2\end{aligned}$$

Thus, NaCl is the limiting reactant.

$$\begin{aligned}\text{Mass (g) of PbCl}_2 &= 0.221 \text{ mol PbCl}_2 \times \frac{278.1 \text{ g PbCl}_2}{1 \text{ mol PbCl}_2} \\ &= 61.5 \text{ g PbCl}_2\end{aligned}$$

(b) Using “Ac” for acetate ion and with NaCl limiting:

Initial	0.402	0.442	0	0
Change	-0.221	-0.442	+0.221	+0.442
Final	0.181	0	0.221	0.442

For $\text{Hg(NO}_3)_2$:

$$\begin{aligned}\text{Amount (mol) of Hg(NO}_3)_2 &= 0.050 \text{ L Hg(NO}_3)_2 \times \frac{0.010 \text{ mol Hg(NO}_3)_2}{1 \text{ L Hg(NO}_3)_2} \\ &= 5.0 \times 10^{-4} \text{ mol Hg(NO}_3)_2\end{aligned}$$

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS (continued)

Amount (mol) of HgS

$$= 5.0 \times 10^{-4} \text{ mol Hg(NO}_3)_2 \times \frac{1 \text{ mol HgS}}{1 \text{ mol Hg(NO}_3)_2}$$

$$= 5.0 \times 10^{-4} \text{ mol HgS}$$

For Na₂S:

$$\text{Amount (mol) of Na}_2\text{S} = 0.020 \text{ L Na}_2\text{S} \times \frac{0.10 \text{ mol Na}_2\text{S}}{1 \text{ L Na}_2\text{S}}$$

$$= 2.0 \times 10^{-3} \text{ mol Na}_2\text{S}$$

$$\text{Amount (mol) of HgS} = 2.0 \times 10^{-3} \text{ mol Na}_2\text{S} \times \frac{1 \text{ mol HgS}}{1 \text{ mol Na}_2\text{S}}$$

$$= 2.0 \times 10^{-3} \text{ mol HgS}$$

Thus, Hg(NO₃)₂ is the limiting reactant.

$$\text{Mass (g) of HgS} = 5.0 \times 10^{-4} \text{ mol HgS} \times \frac{232.7 \text{ g HgS}}{1 \text{ mol HgS}}$$

$$= 0.12 \text{ g HgS}$$

(b)

Amount (mol)	Hg(NO ₃) ₂	+ Na ₂ S	→	HgS	+ 2NaNO ₃
Initial	5.0 × 10 ⁻⁴	2.0 × 10 ⁻³		0	0
Change	-5.0 × 10 ⁻⁴	-5.0 × 10 ⁻⁴		+5.0 × 10 ⁻⁴	+5.0 × 10 ⁻⁴
Final	0	1.5 × 10 ⁻³		5.0 × 10 ⁻⁴	1.0 × 10 ⁻³

4.11A

$$\text{Amount (mol) of OH}^- \text{ ions} = 451 \text{ mL} \times \frac{1 \text{ L}}{10^3 \text{ mL}}$$

$$\times \frac{0.0120 \text{ mol Ca(OH)}_2}{1 \text{ L soln}}$$

$$\times \frac{2 \text{ mol OH}^-}{1 \text{ mol Ca(OH)}_2}$$

$$= 0.0108 \text{ mol OH}^- \text{ ions}$$

4.11B

$$\text{No. of H}^+ \text{ ions} = 65.5 \text{ mL} \times \frac{1 \text{ L}}{10^3 \text{ mL}} \times \frac{0.722 \text{ mol HCl}}{1 \text{ L soln}}$$

$$\times \frac{1 \text{ mol H}^+}{1 \text{ mol HCl}} \times \frac{6.022 \times 10^{23} \text{ H}^+ \text{ ions}}{1 \text{ mol H}^+}$$

$$= 2.85 \times 10^{22} \text{ H}^+ \text{ ions}$$

4.12A

HNO₂ is a weak acid and Sr(OH)₂ is a strong base.The salt is strontium nitrite, Sr(NO₂)₂, and Sr²⁺ is the spectator ion.

4.12B

The salt is calcium bromide, CaBr₂.

$$\text{Mass (g) of Al(OH)}_3 = 3.4 \times 10^{-2} \text{ L HCl soln}$$

$$\times \frac{0.10 \text{ mol HCl}}{1 \text{ L soln}} \times \frac{1 \text{ mol Al(OH)}_3}{3 \text{ mol HCl}}$$

$$\times \frac{78.00 \text{ g Al(OH)}_3}{1 \text{ mol Al(OH)}_3}$$

$$= 0.088 \text{ g Al(OH)}_3$$

$$\text{Mass (g) of HC}_9\text{H}_7\text{O}_4$$

$$= 14.10 \text{ mL NaOH soln} \times \frac{1 \text{ L}}{10^3 \text{ mL}} \times \frac{0.128 \text{ mol NaOH}}{1 \text{ L soln}}$$

$$\times \frac{1 \text{ mol HC}_9\text{H}_7\text{O}_4}{1 \text{ mol NaOH}} \times \frac{180.15 \text{ g HC}_9\text{H}_7\text{O}_4}{1 \text{ mol HC}_9\text{H}_7\text{O}_4}$$

$$= 0.325 \text{ g HC}_9\text{H}_7\text{O}_4$$

$$\text{Volume (L) of soln} = 50.00 \text{ mL HCl soln}$$

$$\times \frac{1 \text{ L}}{10^3 \text{ mL}} \times \frac{0.100 \text{ mol HCl}}{1 \text{ L soln}}$$

$$\times \frac{1 \text{ mol Ba(OH)}_2}{2 \text{ mol HCl}} \times \frac{1 \text{ L soln}}{0.1292 \text{ mol Ba(OH)}_2}$$

$$= 0.01935 \text{ L}$$

$$\text{Amount (mol) of KOH} = 20.00 \text{ mL HNO}_3 \text{ soln} \times \frac{1 \text{ L}}{10^3 \text{ mL}}$$

$$\times \frac{0.2452 \text{ mol HNO}_3}{1 \text{ L soln}}$$

$$\times \frac{1 \text{ mol KOH}}{1 \text{ mol HNO}_3}$$

$$= 0.004904 \text{ mol KOH}$$

$$\text{Molarity of KOH} = \frac{0.004904 \text{ mol KOH}}{18.15 \text{ mL}} \times \frac{10^3 \text{ mL}}{1 \text{ L}}$$

$$= 0.2702 \text{ M}$$

4.16A

Redox; O.N. of N decreases, and O.N. of Cl increases. NCl₃ is both the reducing and the oxidizing agent.

Not redox; no changes in O.N. values

Redox; O.N. of S increases, and O.N. of O decreases. H₂S is the reducing agent; O₂ is the oxidizing agent.

Not redox; no changes in O.N. values

Redox; O.N. of O decreases, and O.N. of C increases. C₂H₆ is the reducing agent; O₂ is the oxidizing agent.

Redox; O.N. of I decreases, and O.N. of C increases. CO is the reducing agent; I₂O₅ is the oxidizing agent.

4.17A (a) Amount (mol) of Ca²⁺

$$\begin{aligned} &= 6.53 \text{ mL soln} \times \frac{1 \text{ L}}{10^3 \text{ mL}} \\ &\quad \times \frac{4.56 \times 10^{-3} \text{ mol KMnO}_4}{1 \text{ L soln}} \\ &\quad \times \frac{5 \text{ mol CaC}_2\text{O}_4}{2 \text{ mol KMnO}_4} \times \frac{1 \text{ mol Ca}^{2+}}{1 \text{ mol CaC}_2\text{O}_4} \\ &= 7.44 \times 10^{-5} \text{ mol Ca}^{2+} \end{aligned}$$

$$\begin{aligned} \text{Molarity of Ca}^{2+} &= \frac{7.44 \times 10^{-5} \text{ mol Ca}^{2+}}{2.50 \text{ mL milK}} \times \frac{10^3 \text{ mL}}{1 \text{ L}} \\ &= 2.98 \times 10^{-2} \text{ M Ca}^{2+} \end{aligned}$$

$$\begin{aligned} (b) \text{ Conc. of Ca}^{2+} (\text{g/L}) &= \frac{2.98 \times 10^{-2} \text{ mol Ca}^{2+}}{1 \text{ L}} \times \frac{40.08 \text{ g Ca}^{2+}}{1 \text{ mol Ca}^{2+}} \\ &= \frac{1.19 \text{ g Ca}^{2+}}{1 \text{ L}} \end{aligned}$$

Yes, the calculated value is close to the typical value.

4.17B (a) Amount (mol) of Fe²⁺

$$\begin{aligned} &= 21.85 \text{ mL soln} \times \frac{1 \text{ L}}{10^3 \text{ mL}} \times \frac{0.250 \text{ mol K}_2\text{Cr}_2\text{O}_7}{1 \text{ L soln}} \\ &\quad \times \frac{6 \text{ mol FeSO}_4}{1 \text{ mol K}_2\text{Cr}_2\text{O}_7} \times \frac{1 \text{ mol Fe}^{2+}}{1 \text{ mol FeSO}_4} \\ &= 0.0328 \text{ mol Fe}^{2+} \end{aligned}$$

$$\begin{aligned} \text{Molarity of Fe}^{2+} &= \frac{0.0328 \text{ mol Fe}^{2+}}{30.0 \text{ mL soln}} \times \frac{10^3 \text{ mL}}{1 \text{ L}} \\ &= 1.09 \text{ M Fe}^{2+} \end{aligned}$$

$$\begin{aligned} (b) \text{ Mass (g) of Fe} &= 0.0328 \text{ mol Fe}^{2+} \times \frac{1 \text{ mol Fe}}{1 \text{ mol Fe}^{2+}} \\ &\quad \times \frac{55.85 \text{ g Fe}}{1 \text{ mol Fe}} \\ &= 1.83 \text{ g Fe} \end{aligned}$$

$$\begin{aligned} \text{Mass \% of Fe} &= \frac{\text{mass of Fe}}{\text{mass of iron ore sample}} \times 100 \\ &= \frac{1.83 \text{ g Fe}}{2.58 \text{ g ore}} \times 100 = 70.9\% \end{aligned}$$

4.18A (a) Combination: S₈(s) + 16F₂(g) → 8SF₄(g)
S₈ is the reducing agent; F₂ is the oxidizing agent.

(b) Displacement:

Cl₂ is the oxidizing agent; CsI is the reducing agent.

(c) Displacement:

Cr is the reducing agent; Ni(NO₃)₂ is the oxidizing agent.

4.18B (a) Displacement: Co(s) + 2HCl(aq) →

Co is the reducing agent; HCl is the oxidizing agent.

(b) Combination: 2SO₂(g) + O₂(g) → 2SO₃(g)

SO₂ is the reducing agent; O₂ is the oxidizing agent.

(c) Decomposition: 2N₂O₅(s) → 4NO₂(g) + O₂(g)

N₂O₅ is both the oxidizing and the reducing agent.

PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

Solution Concentration and the Role of Water as a Solvent

(Sample Problems 4.1 to 4.6)

Concept Review Questions

4.1 Box A represents one unit volume of solution A. Which box—B, C, or D—represents one unit volume after adding enough solvent to solution A to (a) triple its volume; (b) double its volume; (c) quadruple its volume?

4.2 A mathematical equation useful for dilution calculations is $M_{\text{dil}} \times V_{\text{dil}} = M_{\text{conc}} \times V_{\text{conc}}$. (a) What does each symbol mean, and why does the equation work? (b) Given the volume and molarity of a CaCl_2 solution, how do you determine the amount (mol) and the mass (g) of solute?

4.3 Six different aqueous solutions (with solvent molecules omitted for clarity) are represented in the beakers below, and their total volumes are noted.

(a) Which solution has the highest molarity? (b) Which solutions have the same molarity? (c) If you mix solutions A and C, does the resulting solution have a higher molarity than, a lower molarity than, or the same molarity as solution B? (d) After 50. mL of water is added to solution D, is its molarity higher than, lower than, or the same as the molarity of solution F after 75 mL is added to it? (e) How much solvent must be evaporated from solution E for it to have the same molarity as solution A?

4.4 Are the following instructions for diluting a 10.0 M solution to a 1.00 M solution correct: “Take 100.0 mL of the 10.0 M solution and add 900.0 mL water”? Explain.

4.5 What two factors cause water to be polar?

4.6 What types of substances are most likely to be soluble in water?

4.7 What must be present in an aqueous solution for it to conduct an electric current? What general classes of compounds form solutions that conduct?

4.8 What occurs on the molecular level when an ionic compound dissolves in water?

4.9 Which of the following scenes best represents how the ions occur in an aqueous solution of (a) CaCl_2 ; (b) Li_2SO_4 ; (c) NH_4Br ?

4.10 Which of the following scenes best represents a volume from a solution of magnesium nitrate?

4.11 Why are some ionic compounds soluble in water and others are not?

4.12 Why are some covalent compounds soluble in water and others are not?

4.13 Some covalent compounds dissociate into ions in water. What atom do these compounds have in their structures? What type of solution do they form? Name three examples of such a solution.

Skill-Building Exercises (grouped in similar pairs)

4.14 Is each of the following very soluble in water? Explain.

- (a) Benzene, C_6H_6 (b) Sodium hydroxide
(c) Ethanol, $\text{CH}_3\text{CH}_2\text{OH}$ (d) Potassium acetate

4.15 Is each of the following very soluble in water? Explain.

- (a) Lithium nitrate (b) Glycine, $\text{H}_2\text{NCH}_2\text{COOH}$
(c) Pentane (d) Ethylene glycol, $\text{HOCH}_2\text{CH}_2\text{OH}$

4.16 Does an aqueous solution of each of the following conduct an electric current? Explain.

- (a) Cesium bromide (b) Hydrogen iodide

4.17 Does an aqueous solution of each of the following conduct an electric current? Explain.

- (a) Potassium sulfate (b) Sucrose, $\text{C}_{12}\text{H}_{22}\text{O}_{11}$

4.18 How many total moles of ions are released when each of the following dissolves in water?

- (a) 0.32 mol of NH_4Cl (b) 25.4 g of $\text{Ba}(\text{OH})_2 \cdot 8\text{H}_2\text{O}$
(c) 3.55×10^{19} formula units of LiCl

4.19 How many total moles of ions are released when each of the following dissolves in water?

- (a) 0.805 mol of Rb_2SO_4 (b) 3.85×10^{-3} g of $\text{Ca}(\text{NO}_3)_2$
(c) 4.03×10^{19} formula units of $\text{Sr}(\text{HCO}_3)_2$

4.20 How many total moles of ions are released when each of the following dissolves in water?

- (a) 0.75 mol of K_3PO_4 (b) 6.88×10^{-3} g of $\text{NiBr}_2 \cdot 3\text{H}_2\text{O}$
(c) 2.23×10^{22} formula units of FeCl_3

4.21 How many total moles of ions are released when each of the following dissolves in water?

- (a) 0.734 mol of Na_2HPO_4 (b) 3.86 g of $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$
 (c) 8.66×10^{20} formula units of NiCl_2

4.22 Calculate each of the following quantities:

- (a) Mass (g) of solute in 185.8 mL of 0.267 *M* calcium acetate
 (b) Molarity of 500. mL of solution containing 21.1 g of potassium iodide
 (c) Amount (mol) of solute in 145.6 L of 0.850 *M* sodium cyanide

4.23 Calculate each of the following quantities:

- (a) Volume (mL) of 2.26 *M* potassium hydroxide that contains 8.42 g of solute
 (b) Number of Cu^{2+} ions in 52 L of 2.3 *M* copper(II) chloride
 (c) Molarity of 275 mL of solution containing 135 mmol of glucose

4.24 Calculate each of the following quantities:

- (a) Mass (g) of solute needed to make 475 mL of 5.62×10^{-2} *M* potassium sulfate
 (b) Molarity of a solution that contains 7.25 mg of calcium chloride in each milliliter
 (c) Number of Mg^{2+} ions in each milliliter of 0.184 *M* magnesium bromide

4.25 Calculate each of the following quantities:

- (a) Molarity of the solution resulting from dissolving 46.0 g of silver nitrate in enough water to give a final volume of 335 mL
 (b) Volume (L) of 0.385 *M* manganese(II) sulfate that contains 63.0 g of solute
 (c) Volume (mL) of 6.44×10^{-2} *M* adenosine triphosphate (ATP) that contains 1.68 mmol of ATP

4.26 How many moles and how many ions of each type are present in each of the following?

- (a) 130 mL of 0.45 *M* aluminum chloride
 (b) 9.80 mL of a solution containing 2.59 g lithium sulfate/L
 (c) 245 mL of a solution containing 3.68×10^{22} formula units of potassium bromide per liter

4.27 How many moles and how many ions of each type are present in each of the following?

- (a) 88 mL of 1.75 *M* magnesium chloride
 (b) 321 mL of a solution containing 0.22 g aluminum sulfate/L
 (c) 1.65 L of a solution containing 8.83×10^{21} formula units of cesium nitrate per liter

4.28 Calculate each of the following quantities:

- (a) Molarity of a solution prepared by diluting 37.00 mL of 0.250 *M* potassium chloride to 150.00 mL
 (b) Molarity of a solution prepared by diluting 25.71 mL of 0.0706 *M* ammonium sulfate to 500.00 mL
 (c) Molarity of sodium ion in a solution made by mixing 3.58 mL of 0.348 *M* sodium chloride with 500. mL of 6.81×10^{-2} *M* sodium sulfate (assume volumes are additive)

4.29 Calculate each of the following quantities:

- (a) Volume (L) of 2.050 *M* copper(II) nitrate that must be diluted with water to prepare 750.0 mL of a 0.8543 *M* solution
 (b) Volume (L) of 1.63 *M* calcium chloride that must be diluted with water to prepare 350. mL of a 2.86×10^{-2} *M* chloride ion solution
 (c) Final volume (L) of a 0.0700 *M* solution prepared by diluting 18.0 mL of 0.155 *M* lithium carbonate with water

4.30 A sample of concentrated nitric acid has a density of 1.41 g/mL and contains 70.0% HNO_3 by mass.

- (a) What mass (g) of HNO_3 is present per liter of solution?
 (b) What is the molarity of the solution?

4.31 Concentrated sulfuric acid (18.3 *M*) has a density of 1.84 g/mL.

- (a) How many moles of H_2SO_4 are in each milliliter of solution?
 (b) What is the mass % of H_2SO_4 in the solution?

Problems in Context

4.32 Ordinary household bleach is an aqueous solution of sodium hypochlorite. What is the molarity of a bleach solution that contains 20.5 g of sodium hypochlorite in 375 mL? 20.5 g of sodium hypochlorite in 375 mL?

4.33 Muriatic acid, an industrial grade of concentrated HCl, is used to clean masonry and cement. Its concentration is 11.7 *M*.

- (a) Write instructions for diluting the concentrated acid to make 3.0 gallons of 3.5 *M* acid for routine use (1 gal = 4 qt; 1 qt = 0.946 L). (b) How many milliliters of the muriatic acid solution contain 9.66 g of HCl?

4.34 To study a marine organism, a biologist prepares a 1.00-kg sample to simulate the ion concentrations in seawater. She mixes 26.5 g of NaCl, 2.40 g of MgCl_2 , 3.35 g of MgSO_4 , 1.20 g of CaCl_2 , 1.05 g of KCl, 0.315 g of NaHCO_3 , and 0.098 g of NaBr in distilled water. (a) If the density of the solution is 1.025 g/cm³, what is the molarity of each ion? (b) What is the total molarity of alkali metal ions? (c) What is the total molarity of alkaline earth metal ions? (d) What is the total molarity of anions?

4.35 Water “softeners” remove metal ions such as Ca^{2+} and Fe^{3+} by replacing them with enough Na^+ ions to maintain the same number of positive charges in the solution. If 1.0×10^3 L of “hard” water is 0.015 *M* Ca^{2+} and 0.0010 *M* Fe^{3+} , how many moles of Na^+ are needed to replace these ions?

Precipitation Reactions

(Sample Problems 4.7 to 4.10)

Concept Review Questions

4.36 Which ions do not appear in a net ionic equation? Why?

4.37 Write two sets of equations (both molecular and total ionic) with different reactants that have the same net ionic equation as the following equation:

4.38 Why do some pairs of ions precipitate and others do not?

4.39 Use Table 4.1 to determine which of the following combinations leads to a precipitation reaction. How can you identify the spectator ions in the reaction?

- (a) Calcium nitrate(aq) + sodium chloride(aq) $\longrightarrow$
 (b) Potassium chloride(aq) + lead(II) nitrate(aq) $\longrightarrow$

4.40 The beakers represent the aqueous reaction of AgNO_3 and NaCl. Silver ions are gray. What colors are used to represent NO_3^- , Na^+ , and Cl^- ? Write molecular, total ionic, and net ionic equations for the reaction.

Skill-Building Exercises (grouped in similar pairs)

4.41 Complete the following precipitation reactions with balanced molecular, total ionic, and net ionic equations:

- (a) $\text{Hg}_2(\text{NO}_3)_2(\text{aq}) + \text{KI}(\text{aq}) \longrightarrow$ (b) $\text{FeSO}_4(\text{aq}) + \text{Sr}(\text{OH})_2(\text{aq}) \longrightarrow$

4.42 Complete the following precipitation reactions with balanced molecular, total ionic, and net ionic equations:

4.43 When each of the following pairs of aqueous solutions is mixed, does a precipitation reaction occur? If so, write balanced molecular, total ionic, and net ionic equations:

- (a) Sodium nitrate + copper(II) sulfate
(b) Ammonium bromide + silver nitrate

4.44 When each of the following pairs of aqueous solutions is mixed, does a precipitation reaction occur? If so, write balanced molecular, total ionic, and net ionic equations:

- (a) Potassium carbonate + barium hydroxide
(b) Aluminum nitrate + sodium phosphate

4.45 When each of the following pairs of aqueous solutions is mixed, does a precipitation reaction occur? If so, write balanced molecular, total ionic, and net ionic equations.

- (a) Potassium chloride + iron(III) nitrate
(b) Ammonium sulfate + barium chloride

4.46 When each of the following pairs of aqueous solutions is mixed, does a precipitation reaction occur? If so, write balanced molecular, total ionic, and net ionic equations:

- (a) Sodium sulfide + nickel(II) sulfate
(b) Lead(II) nitrate + potassium bromide

4.47 If 38.5 mL of lead(II) nitrate solution reacts completely with excess sodium iodide solution to yield 0.628 g of precipitate, what is the molarity of lead(II) ion in the original solution?

4.48 If 25.0 mL of silver nitrate solution reacts with excess potassium chloride solution to yield 0.842 g of precipitate, what is the molarity of silver ion in the original solution?

4.49 How many grams of barium sulfate form when 35.0 mL of 0.160 M barium chloride reacts with 58.0 mL of 0.065 M sodium sulfate?

4.50 How many grams of iron(III) sulfide form when 62.0 mL of 0.135 M iron(III) chloride reacts with 45.0 mL of 0.285 M calcium sulfide?

4.51 With ions shown as spheres and solvent molecules omitted for clarity, the circle illustrates the solid formed when a solution containing K^+ , Mg^{2+} , Ag^+ , or Pb^{2+} (green) is mixed with one containing ClO_4^- , NO_3^- , or SO_4^{2-} (yellow). (a) Identify the solid. (b) Write a balanced net ionic equation for the reaction. (c) If each sphere represents 5.0×10^{-4} mol of ion, what mass of product forms?

4.52 The precipitation reaction between 25.0 mL of a solution containing a cation (purple) and 35.0 mL of a solution containing an anion (green) is depicted below (with ions shown as spheres and solvent molecules omitted for clarity).

(a) Given the following choices of reactants, write balanced total ionic and net ionic equations that best represent the reaction:

- (1) $\text{KNO}_3(aq) + \text{CuCl}_2(aq) \longrightarrow$
(2) $\text{NaClO}_4(aq) + \text{CaCl}_2(aq) \longrightarrow$

(b) If each sphere represents 2.5×10^{-3} mol of ion, find the total number of ions present.

(c) What is the mass of solid formed?

4.53 A 1.50-g sample of an unknown alkali-metal carbonate was dissolved in water, and 31.10 mL of 0.350 M CaCl_2 was required to precipitate all the carbonate ions as CaCO_3 . Give the name and formula of the unknown compound.

4.54 A 0.750-g sample of a compound that might be iron(II) chloride, nickel(II) chloride, or zinc chloride is dissolved in water, and 22.40 mL of 0.515 M AgNO_3 is required to completely precipitate all the chloride ion as AgCl . Name the compound, and write its formula.

Problems in Context

4.55 The mass percent of Cl^- in a seawater sample is determined by titrating 25.00 mL of seawater with AgNO_3 solution, causing a precipitation reaction. An indicator is used to detect the end point, which occurs when free Ag^+ ion is present in solution after all the Cl^- has reacted. If 53.63 mL of 0.2970 M AgNO_3 is required to reach the end point, what is the mass percent of Cl^- in the seawater (d of seawater = 1.024 g/mL)?

4.56 Aluminum sulfate, known as *cake alum*, has a wide range of uses, from dyeing leather and cloth to purifying sewage. In aqueous solution, it reacts with base to form a white precipitate. (a) Write balanced total and net ionic equations for its reaction with aqueous NaOH . (b) What mass of precipitate forms when 185.5 mL of 0.533 M NaOH is added to 627 mL of a solution that contains 15.8 g of aluminum sulfate per liter?

Acid-Base Reactions

(Sample Problems 4.11 to 4.14)

Concept Review Questions

4.57 Is the total ionic equation the same as the net ionic equation when $\text{Sr}(\text{OH})_2(aq)$ and $\text{H}_2\text{SO}_4(aq)$ react? Explain.

4.58 Write a general equation for a neutralization reaction.

4.59 (a) Name three common strong acids. (b) Name three common strong bases. (c) What is a characteristic behavior of a strong acid or a strong base?

4.60 (a) Name three common weak acids. (b) Name one common weak base. (c) What is the major difference between a weak acid and a strong acid or between a weak base and a strong base, and what experiment would you perform to observe it?

4.61 Do either of the following reactions go to completion? If so, what factor(s) cause(s) each to do so?

4.62 (a) The net ionic equation for the aqueous neutralization reaction between acetic acid and sodium hydroxide is different from that for the reaction between hydrochloric acid and sodium hydroxide. Explain by writing balanced net ionic equations. (b) For a solution of acetic acid in water, list the major species in decreasing order of concentration.

Skill-Building Exercises (grouped in similar pairs)

4.63 How many moles of H^+ ions are present in each of the following aqueous solutions?

- (a) 1.40 L of 0.25 M perchloric acid
(b) 6.8 mL of 0.92 M nitric acid
(c) 2.6 L of 0.085 M hydrochloric acid

4.64 How many moles of H^+ ions are present in each of the following aqueous solutions?

- (a) 1.4 mL of 0.75 *M* hydrobromic acid
- (b) 2.47 mL of 1.98 *M* hydriodic acid
- (c) 395 mL of 0.270 *M* nitric acid

4.65 Complete the following acid-base reactions with balanced molecular, total ionic, and net ionic equations:

- (a) Potassium hydroxide(aq) + hydrobromic acid(aq) $\longrightarrow$
- (b) Ammonia(aq) + hydrochloric acid(aq) $\longrightarrow$

4.66 Complete the following acid-base reactions with balanced molecular, total ionic, and net ionic equations:

- (a) Cesium hydroxide(aq) + nitric acid(aq) $\longrightarrow$
- (b) Calcium hydroxide(aq) + acetic acid(aq) $\longrightarrow$

4.67 Limestone (calcium carbonate) is insoluble in water but dissolves in aqueous hydrochloric acid. Write balanced total ionic and net ionic equations.

4.68 Zinc hydroxide is insoluble in water but dissolves in aqueous nitric acid. Why? Write balanced total ionic and net ionic equations.

4.69 How many milliliters of 0.383 *M* HCl are needed to react with 16.2 g of CaCO_3 ?

4.70 How many grams of NaH_2PO_4 are needed to react with 43.74 mL of 0.285 *M* NaOH?

4.71 If 25.98 mL of 0.1180 *M* KOH solution reacts with 52.50 mL of CH_3COOH solution, what is the molarity of the acid solution?

4.72 If 26.25 mL of 0.1850 *M* NaOH solution reacts with 25.00 mL of H_2SO_4 , what is the molarity of the acid solution?

Problems in Context

4.73 An auto mechanic spills 88 mL of 2.6 *M* H_2SO_4 solution from an auto battery. How many milliliters of 1.6 *M* NaHCO_3 must be poured on the spill to react completely with the sulfuric acid?

4.74 Sodium hydroxide is used extensively in acid-base titrations because it is a strong, inexpensive base. A sodium hydroxide solution was standardized by titrating 25.00 mL of 0.1528 *M* standard hydrochloric acid. The initial buret reading of the sodium hydroxide was 2.24 mL, and the final reading was 39.21 mL. What was the molarity of the base solution?

4.75 An unknown amount of acid can often be determined by adding an excess of base and then “back-titrating” the excess. A 0.3471-g sample of a mixture of oxalic acid, which has two ionizable protons, and benzoic acid, which has one, is treated with 100.0 mL of 0.1000 *M* NaOH. The excess NaOH is titrated with 20.00 mL of 0.2000 *M* HCl. Find the mass % of benzoic acid.

4.76 One of the first steps in the enrichment of uranium for use in nuclear power plants involves a displacement reaction between UO_2 and aqueous HF:

How many liters of 2.40 *M* HF will react with 2.15 kg of UO_2 ?

4.77 A mixture of bases can sometimes be the active ingredient in antacid tablets. If 0.4826 g of a mixture of $\text{Al}(\text{OH})_3$ and $\text{Mg}(\text{OH})_2$ is neutralized with 17.30 mL of 1.000 *M* HNO_3 , what is the mass % of $\text{Al}(\text{OH})_3$ in the mixture?

Oxidation-Reduction (Redox) Reactions

(Sample Problems 4.15 to 4.17)

Concept Review Questions

4.78 Describe how to determine the oxidation number of sulfur in (a) H_2S and (b) SO_3^{2-} .

4.79 Is the following a redox reaction? Explain.

4.80 Explain why an oxidizing agent undergoes reduction.

4.81 Why must every redox reaction involve an oxidizing agent and a reducing agent?

4.82 In which of the following equations does sulfuric acid act as an oxidizing agent? In which does it act as an acid? Explain.

4.83 Identify the oxidizing agent and the reducing agent in the following reaction, and explain your answer:

Skill-Building Exercises (grouped in similar pairs)

4.84 Give the oxidation number of carbon in each of the following:

- (a) CF_2Cl_2
- (b) $\text{Na}_2\text{C}_2\text{O}_4$
- (c) HCO_3^-
- (d) C_2H_6

4.85 Give the oxidation number of bromine in each of the following:

- (a) KBr
- (b) BrF_3
- (c) HBrO_3
- (d) CBr_4

4.86 Give the oxidation number of nitrogen in each of the following:

- (a) NH_2OH
- (b) N_2F_4
- (c) NH_4^+
- (d) HNO_2

4.87 Give the oxidation number of sulfur in each of the following:

- (a) SOCl_2
- (b) H_2S_2
- (c) H_2SO_3
- (d) Na_2S

4.88 Give the oxidation number of arsenic in each of the following:

- (a) AsH_3
- (b) H_2AsO_4^-
- (c) AsCl_3

4.89 Give the oxidation number of phosphorus in each of the following:

- (a) $\text{H}_2\text{P}_2\text{O}_7^{2-}$
- (b) PH_4^+
- (c) PCl_5

4.90 Give the oxidation number of manganese in each of the following:

- (a) MnO_4^{2-}
- (b) Mn_2O_3
- (c) KMnO_4

4.91 Give the oxidation number of chromium in each of the following:

- (a) CrO_3
- (b) $\text{Cr}_2\text{O}_7^{2-}$
- (c) $\text{Cr}_2(\text{SO}_4)_3$

4.92 Identify the oxidizing and reducing agents in the following reactions:

4.93 Identify the oxidizing and reducing agents in the following reactions:

4.94 Identify the oxidizing and reducing agents in the following reactions:

4.95 Identify the oxidizing and reducing agents in the following reactions:

Problems in Context

4.96 The active agent in many hair bleaches is hydrogen peroxide. The amount of H_2O_2 in 14.8 g of hair bleach was determined by titration with a standard potassium permanganate solution:

- How many moles of MnO_4^- were required for the titration if 43.2 mL of 0.105 M KMnO_4 was needed to reach the end point?
- How many moles of H_2O_2 were present in the 14.8-g sample of bleach?
- How many grams of H_2O_2 were in the sample?
- What is the mass percent of H_2O_2 in the sample?
- What is the reducing agent in the redox reaction?

4.97 A person's blood alcohol ($\text{C}_2\text{H}_5\text{OH}$) level can be determined by titrating a sample of blood plasma with a potassium dichromate solution. The balanced equation is

If 35.46 mL of 0.05961 M $\text{Cr}_2\text{O}_7^{2-}$ is required to titrate 28.00 g of plasma, what is the mass percent of alcohol in the blood?

Elements in Redox Reactions

(Sample Problem 4.18)

Concept Review Questions

4.98 Which type of redox reaction leads to each of the following?

- An increase in the number of substances
- A decrease in the number of substances
- No change in the number of substances

4.99 Why do decomposition redox reactions typically have compounds as reactants, whereas combination redox and displacement redox reactions have one or more elements as reactants?

4.100 Which of the types of reactions discussed in Section 4.5 commonly produce more than one compound?

4.101 Are all combustion reactions redox reactions? Explain.

4.102 Give one example of a combination reaction that is a redox reaction and another that is not a redox reaction.

Skill-Building Exercises (grouped in similar pairs)

4.103 Balance each of the following redox reactions and classify it as a combination, decomposition, or displacement reaction:

4.104 Balance each of the following redox reactions and classify it as a combination, decomposition, or displacement reaction:

4.105 Balance each of the following redox reactions and classify it as a combination, decomposition, or displacement reaction:

4.106 Balance each of the following redox reactions and classify it as a combination, decomposition, or displacement reaction:

4.107 Predict the product(s) and write a balanced equation for each of the following redox reactions:

4.108 Predict the product(s) and write a balanced equation for each of the following redox reactions:

4.109 Predict the product(s) and write a balanced equation for each of the following redox reactions:

4.110 Predict the product(s) and write a balanced equation for each of the following redox reactions:

4.111 Predict the product(s) and write a balanced equation for each of the following redox reactions:

- Cesium + iodine $\longrightarrow$
- Aluminum + aqueous manganese(II) sulfate $\longrightarrow$
- Sulfur dioxide + oxygen $\longrightarrow$
- Butane + oxygen $\longrightarrow$
- Write a balanced net ionic equation for (b).

4.112 Predict the product(s) and write a balanced equation for each of the following redox reactions:

- Pentane (C_5H_{12}) + oxygen $\longrightarrow$
- Phosphorus trichloride + chlorine $\longrightarrow$
- Zinc + hydrobromic acid $\longrightarrow$
- Aqueous potassium iodide + bromine $\longrightarrow$
- Write a balanced net ionic equation for (d).

4.113 How many grams of O_2 can be prepared from the thermal decomposition of 4.27 kg of HgO ? Name and calculate the mass (in kg) of the other product.

4.114 How many grams of chlorine gas can be produced from the electrolytic decomposition of 874 g of calcium chloride? Name and calculate the mass (in g) of the other product.

4.115 In a combination reaction, 1.62 g of lithium is mixed with 6.50 g of oxygen.

- Which reactant is present in excess?
- How many moles of product are formed?
- After reaction, how many grams of each reactant and product are present?

4.116 In a combination reaction, 2.22 g of magnesium is heated with 3.75 g of nitrogen.

- Which reactant is present in excess?
- How many moles of product are formed?
- After reaction, how many grams of each reactant and product are present?

4.117 A mixture of KClO_3 and KCl with a mass of 0.950 g was heated to produce O_2 . After heating, the mass of residue was 0.700 g. Assuming all the KClO_3 decomposed to KCl and O_2 , calculate the mass percent of KClO_3 in the original mixture.

4.118 A mixture of CaCO_3 and CaO weighing 0.693 g was heated to produce gaseous CO_2 . After heating, the remaining solid weighed 0.508 g. Assuming all the CaCO_3 broke down to CaO and CO_2 , calculate the mass percent of CaCO_3 in the original mixture.

Problems in Context

4.119 Before arc welding was developed, a displacement reaction involving aluminum and iron(III) oxide was commonly used to produce molten iron. Called the thermite process, this reaction was used, for example, to connect sections of iron rails for train tracks. Calculate the mass of molten iron produced when 1.50 kg of aluminum reacts with 25.0 mol of iron(III) oxide.

4.120 Iron reacts rapidly with chlorine gas to form a reddish-brown, ionic compound (A), which contains iron in the higher of its two common oxidation states. Strong heating decomposes compound A to compound B, another ionic compound, which contains iron in the lower of its two oxidation states. When compound A is formed by the reaction of 50.6 g of Fe and 83.8 g of Cl_2 and then heated, how much compound B forms?

4.121 A sample of impure magnesium was analyzed by allowing it to react with excess HCl solution. After 1.32 g of the impure metal was treated with 0.100 L of 0.750 M HCl, 0.0125 mol of HCl remained. Assuming the impurities do not react, what is the mass % of Mg in the sample?

The Reversibility of Reactions and the Equilibrium State

Concept Review Questions

- 4.122** Why is the equilibrium state said to be “dynamic”?
- 4.123** In a decomposition reaction involving a gaseous product, what must be done for the reaction to reach equilibrium?
- 4.124** Describe what happens on the molecular level when acetic acid dissolves in water.
- 4.125** When either a mixture of NO and Br_2 or pure nitrosyl bromide (NOBr) is placed in a reaction vessel, the product mixture contains NO, Br_2 , and NOBr. Explain.

Problem in Context

4.126 Ammonia is produced by the millions of tons annually for use as a fertilizer. It is commonly made from N_2 and H_2 by the Haber process. Because the reaction reaches equilibrium before going completely to product, the stoichiometric amount of ammonia is not obtained. At a particular temperature and pressure, 10.0 g of H_2 reacts with 20.0 g of N_2 to form ammonia. When equilibrium is reached, 15.0 g of NH_3 has formed. (a) Calculate the percent yield. (b) How many moles of N_2 and H_2 are present at equilibrium?

Comprehensive Problems

4.127 Nutritional biochemists have known for decades that acidic foods cooked in cast-iron cookware can supply significant amounts of dietary iron (ferrous ion). (a) Write a balanced net ionic equation, with oxidation numbers, that supports this fact. (b) Measurements show an increase from 3.3 mg of iron to 49 mg of iron per $\frac{1}{2}$ -cup (125-g) serving during the slow preparation of tomato sauce in a cast-iron pot. How many ferrous ions are present in a 26-oz (737-g) jar of the tomato sauce?

4.128 Limestone (CaCO_3) is used to remove acidic pollutants from smokestack flue gases. It is heated to form lime (CaO), which reacts with sulfur dioxide to form calcium sulfite. Assuming a 70.% yield in the overall reaction, what mass of limestone is required to remove all the sulfur dioxide formed by the combustion of 8.5×10^4 kg of coal that is 0.33 mass % sulfur?

4.129 The brewing industry uses yeast to convert glucose to ethanol. The baking industry uses the carbon dioxide produced in the same reaction to make bread rise:

How many grams of ethanol can be produced from 100. g of glucose? What volume of CO_2 is produced? (Assume 1 mol of gas occupies 22.4 L at the conditions used.)

4.130 A chemical engineer determines the mass percent of iron in an ore sample by converting the Fe to Fe^{2+} in acid and then titrating the Fe^{2+} with MnO_4^- . A 1.1081-g ore sample was dissolved in acid and then titrated with 39.32 mL of 0.03190 M KMnO_4 . The balanced equation is

Calculate the mass percent of iron in the ore.

4.131 Mixtures of CaCl_2 and NaCl are used to melt ice on roads. A dissolved 1.9348-g sample of such a mixture was analyzed by using excess $\text{Na}_2\text{C}_2\text{O}_4$ to precipitate the Ca^{2+} as CaC_2O_4 . The CaC_2O_4 was dissolved in sulfuric acid, and the resulting $\text{H}_2\text{C}_2\text{O}_4$ was titrated with 37.68 mL of 0.1019 M KMnO_4 solution.

- (a) Write the balanced net ionic equation for the precipitation reaction.
- (b) Write the balanced net ionic equation for the titration reaction. (See Sample Problem 4.17.)
- (c) What is the oxidizing agent?
- (d) What is the reducing agent?
- (e) Calculate the mass percent of CaCl_2 in the original sample.

4.132 You are given solutions of HCl and NaOH and must determine their concentrations. You use 27.5 mL of NaOH to titrate 100. mL of HCl and 18.4 mL of NaOH to titrate 50.0 mL of 0.0782 M H_2SO_4 . Find the unknown concentrations.

4.133 The flask represents the products of the titration of 25 mL of sulfuric acid with 25 mL of sodium hydroxide.

- (a) Write balanced molecular, total ionic, and net ionic equations for the reaction.
- (b) If each orange sphere represents 0.010 mol of sulfate ion, how many moles of acid and of base reacted?
- (c) What are the molarities of the acid and the base?

4.134 To find the mass percent of dolomite [$\text{CaMg}(\text{CO}_3)_2$] in a soil sample, a geochemist titrates 13.86 g of soil with 33.56 mL of 0.2516 M HCl. What is the mass percent of dolomite in the soil?

4.135 On a lab exam, you have to find the concentrations of the monoprotic (one proton per molecule) acids HA and HB. You are given 43.5 mL of HA solution in one flask. A second flask contains 37.2 mL of HA, and you add enough HB solution to it to reach a final volume of 50.0 mL. You titrate the first HA solution with 87.3 mL of 0.0906 M NaOH and the mixture of HA and HB in the second flask with 96.4 mL of the NaOH solution. Calculate the molarity of the HA and HB solutions.

4.136 Nitric acid, a major industrial and laboratory acid, is produced commercially by the multistep Ostwald process, which begins with the oxidation of ammonia:

- (a) What are the oxidizing and reducing agents in each step?
- (b) Assuming 100% yield in each step, what mass (in kg) of ammonia must be used to produce 3.0×10^4 kg of HNO_3 ?

4.137 Various data can be used to find the composition of an alloy (a metallic mixture). Show that calculating the mass % of Mg in a magnesium-aluminum alloy ($d = 2.40 \text{ g/cm}^3$) using each of the following pieces of data gives the same answer (within rounding): (a) a sample of the alloy has a mass of 0.263 g (d of Mg = 1.74 g/cm^3 ; d of Al = 2.70 g/cm^3); (b) an identical sample reacting with excess aqueous HCl forms $1.38 \times 10^{-2} \text{ mol}$ of H_2 ; (c) an identical sample reacting with excess O_2 forms 0.483 g of oxide.

4.138 In 1995, Mario Molina, Paul Crutzen, and F. Sherwood Rowland shared the Nobel Prize in chemistry for their work on atmospheric chemistry. One reaction sequence they proposed for the role of chlorine in the decomposition of stratospheric ozone (we'll see another sequence in Chapter 16) is

Over the tropics, O atoms are more common in the stratosphere:

(a) Which, if any, of these are oxidation-reduction reactions?

(b) Write an overall equation combining reactions 1–3.

4.139 Sodium peroxide (Na_2O_2) is often used in self-contained breathing devices, such as those used in fire emergencies, because it reacts with exhaled CO_2 to form Na_2CO_3 and O_2 . How many liters of respired air can react with 80.0 g of Na_2O_2 if each liter of respired air contains 0.0720 g of CO_2 ?

4.140 A student forgets to weigh a mixture of sodium bromide dihydrate and magnesium bromide hexahydrate. Upon strong heating, the sample loses 252.1 mg of water. The mixture of anhydrous salts reacts with excess AgNO_3 solution to form $6.00 \times 10^{-3} \text{ mol}$ of solid AgBr . Find the mass % of each compound in the original mixture.

4.141 A typical formulation for window glass is 75% SiO_2 , 15% Na_2O , and 10% CaO by mass. What masses of sand (SiO_2), sodium carbonate, and calcium carbonate must be combined to produce 1.00 kg of glass after carbon dioxide is driven off by thermal decomposition of the carbonates?

4.142 The quantity of dissolved oxygen (DO) in natural waters is an essential parameter for monitoring survival of most aquatic life. DO is affected by temperature and the amount of organic waste. An earlier method for determining DO involved a two-step process:

(1) The water sample is treated with KI,

(2) The I_2 is titrated with sodium thiosulfate,

A 50.0-mL water sample is treated with KI, and then 15.75 mL of 0.0105 M $\text{Na}_2\text{S}_2\text{O}_3$ is required to reach the end point.

(a) Which substance is oxidized in step 1, and which is reduced in step 2?

(b) What mass (g) of O_2 is dissolved in the water sample?

4.143 Physicians who specialize in sports medicine routinely treat athletes and dancers. Ethyl chloride, a local anesthetic commonly used for simple injuries, is the product of the combination of ethylene with hydrogen chloride:

Assume that 0.100 kg of C_2H_4 and 0.100 kg of HCl react. (a) How many molecules of gas (reactants plus products) are present when the reaction is complete? (b) How many moles of gas are present when half the product forms?

4.144 Thyroxine ($\text{C}_{15}\text{H}_{11}\text{I}_4\text{NO}_4$) is a hormone synthesized by the thyroid gland and used to control many metabolic functions in the body. A physiologist determines the mass percent of thyroxine in

a thyroid extract by igniting 0.4332 g of extract with sodium carbonate, which converts the iodine to iodide. The iodide is dissolved in water, and bromine and hydrochloric acid are added, which convert the iodide to iodate.

(a) How many moles of iodate form per mole of thyroxine?

(b) Excess bromine is boiled off and more iodide is added, which reacts as shown in the following equation:

How many moles of iodine are produced per mole of thyroxine? (*Hint:* Be sure to balance the charges as well as the atoms.) What are the oxidizing and reducing agents in the reaction?

(c) The iodine reacts completely with 17.23 mL of 0.1000 M thiosulfate as shown in the following *unbalanced* equation:

What is the mass percent of thyroxine in the thyroid extract?

4.145 Over time, as their free fatty acid (FFA) content increases, edible fats and oils become rancid. To measure rancidity, the fat or oil is dissolved in ethanol, and any FFA present is titrated with KOH dissolved in ethanol. In a series of tests on olive oil, a stock solution of 0.050 M ethanolic KOH was prepared at 25°C , stored at 0°C , and then placed in a 100-mL buret to titrate oleic acid [an FFA with formula $\text{CH}_3(\text{CH}_2)_7\text{CH}=\text{CH}(\text{CH}_2)_7\text{COOH}$] in the oil. Each of four 10.00-g samples of oil took several minutes to titrate: the first required 19.60 mL, the second 19.80 mL, and the third and fourth 20.00 mL of the ethanolic KOH.

(a) What is the apparent acidity of each sample, in terms of mass % of oleic acid? (*Note:* As the ethanolic KOH warms in the buret, its volume increases by a factor of 0.00104/ $^\circ\text{C}$.)

(b) Is the variation in acidity a random or systematic error? Explain.

(c) What is the actual acidity? How would you demonstrate this?

4.146 A chemist mixes solid AgCl , CuCl_2 , and MgCl_2 in enough water to give a final volume of 50.0 mL.

(a) With ions shown as spheres and solvent molecules omitted for clarity, which scene best represents the resulting mixture?

(b) If each sphere represents $5.0 \times 10^{-3} \text{ mol}$ of ions, what is the total concentration of *dissolved* (separated) ions?

(c) What is the total mass of solid?

4.147 Calcium dihydrogen phosphate, $\text{Ca}(\text{H}_2\text{PO}_4)_2$, and sodium hydrogen carbonate, NaHCO_3 , are ingredients of baking powder that react to produce CO_2 , which causes dough or batter to rise:

If the baking powder contains 31% NaHCO_3 and 35% $\text{Ca}(\text{H}_2\text{PO}_4)_2$ by mass:

- (a) How many moles of CO_2 are produced from 1.00 g of baking powder?
- (b) If 1 mol of CO_2 occupies 37.0 L at 350°F (a typical baking temperature), what volume of CO_2 is produced from 1.00 g of baking powder?

4.148 In a titration of HNO_3 , you add a few drops of phenolphthalein indicator to 50.00 mL of acid in a flask. You quickly add 20.00 mL of 0.0502 M NaOH but overshoot the end point, and the solution turns deep pink. Instead of starting over, you add 30.00 mL of the acid, and the solution turns colorless. Then, it takes 3.22 mL of the NaOH to reach the end point.

- (a) What is the concentration of the HNO_3 solution?
- (b) How many moles of NaOH were in excess after the first addition?

4.149 The active compound in Pepto-Bismol contains C, H, O, and Bi.

(a) When 0.22105 g of the compound was burned in excess O_2 , 0.1422 g of bismuth(III) oxide, 0.1880 g of carbon dioxide, and 0.02750 g of water were formed. What is the empirical formula of the compound?

(b) Given a molar mass of 1086 g/mol, determine the molecular formula.

(c) Complete and balance the acid-base reaction between bismuth(III) hydroxide and salicylic acid ($\text{HC}_7\text{H}_5\text{O}_3$), which is used to form this compound.

(d) A dose of Pepto-Bismol contains 0.600 mg of active ingredient. If the yield of the reaction in part (c) is 88.0%, what mass (in mg) of bismuth(III) hydroxide is required to prepare one dose?

4.150 Two aqueous solutions contain the ions indicated below.

(a) Write balanced molecular, total ionic, and net ionic equations for the reaction that occurs when the solutions are mixed.

(b) If each sphere represents 0.050 mol of ion, what mass (in g) of precipitate forms, assuming 100% yield?

(c) What is the concentration of each ion in solution after reaction?

4.151 In 1997 and 2009, at United Nations conferences on climate change, many nations agreed to expand their research efforts to develop renewable sources of carbon-based fuels. For more than a quarter century, Brazil has been engaged in a program to replace gasoline with ethanol derived from the root crop manioc (cassava).

(a) Write separate balanced equations for the complete combustion of ethanol ($\text{C}_2\text{H}_5\text{OH}$) and of gasoline (represented by the formula C_8H_{18}).

(b) What mass (g) of oxygen is required to burn completely 1.00 L of a mixture that is 90.0% gasoline ($d = 0.742 \text{ g/mL}$) and 10.0% ethanol ($d = 0.789 \text{ g/mL}$) by volume?

(c) If 1.00 mol of O_2 occupies 22.4 L, what volume of O_2 is needed to burn 1.00 L of the mixture?

(d) Air is 20.9% O_2 by volume. What volume of air is needed to burn 1.00 L of the mixture?

4.152 In a car engine, gasoline (represented by C_8H_{18}) does not burn completely, and some CO, a toxic pollutant, forms along with CO_2 and H_2O . If 5.0% of the gasoline forms CO:

- (a) What is the ratio of CO_2 to CO molecules in the exhaust?
- (b) What is the mass ratio of CO_2 to CO?
- (c) What percentage of the gasoline must form CO for the mass ratio of CO_2 to CO to be exactly 1/1?

4.153 The amount of ascorbic acid (vitamin C, $\text{C}_6\text{H}_8\text{O}_6$) in tablets is determined by reaction with bromine and then titration of the hydrobromic acid with standard base:

A certain tablet is advertised as containing 500 mg of vitamin C. One tablet was dissolved in water and reacted with Br_2 . The solution was then titrated with 43.20 mL of 0.1350 M NaOH. Did the tablet contain the advertised quantity of vitamin C?

4.154 In the process of *salting-in*, protein solubility in a dilute salt solution is increased by adding more salt. Because the protein solubility depends on the total ion concentration as well as the ion charge, salts containing doubly charged ions are often more effective at increasing the protein solubility than those containing singly charged ions.

(a) How many grams of MgCl_2 must dissolve to equal the ion concentration of 12.4 g of NaCl?

(b) How many grams of CaS must dissolve?

(c) Which of the three salt solutions would dissolve the most protein?

4.155 At liftoff, a space shuttle used a solid mixture of ammonium perchlorate and aluminum powder to obtain great thrust from the volume change of solid to gas. In the presence of a catalyst, the mixture forms solid aluminum oxide and aluminum trichloride and gaseous water and nitrogen monoxide.

(a) Write a balanced equation for the reaction, and identify the reducing and oxidizing agents.

(b) How many total moles of gas (water vapor and nitrogen monoxide) are produced when 50.0 kg of ammonium perchlorate reacts with a stoichiometric amount of Al?

(c) What is the change in volume from this reaction? (d of $\text{NH}_4\text{ClO}_4 = 1.95 \text{ g/cc}$, d of Al = 2.70 g/cc , d of $\text{Al}_2\text{O}_3 = 3.97 \text{ g/cc}$, and d of $\text{AlCl}_3 = 2.44 \text{ g/cc}$; assume 1 mol of gas occupies 22.4 L.)

4.156 A *reaction cycle* for an element is a series of reactions beginning and ending with that element. In the following copper reaction cycle, copper has either a 0 or a +2 oxidation state. Write balanced molecular and net ionic equations for each step.

(1) Copper metal reacts with aqueous bromine to produce a green-blue solution.

(2) Adding aqueous sodium hydroxide forms a blue precipitate.

(3) The precipitate is heated and turns black (water is released).

(4) The black solid dissolves in nitric acid to give a blue solution.

(5) Adding aqueous sodium phosphate forms a green precipitate.

(6) The precipitate forms a blue solution in sulfuric acid.

(7) Copper metal is recovered from the blue solution when zinc metal is added.

4.157 Two 25.0-mL aqueous solutions, labeled A and B, contain the ions indicated:

(a) If each sphere represents 1.0×10^{-3} mol of ion, will the equivalence point have been reached when all of B has been added to A?

(b) What is the molarity of B?

(c) What additional volume (mL) of B must be added to reach the equivalence point?

- › SI unit conversions (Section 1.3)

During hot air balloon festivals held worldwide each year, hundreds of colorful hot air balloons fill the sky to the delight of spectators on the ground. Some festivals offer balloon rides so that spectators can experience the thrill themselves. Hot air balloons use the principle that hot air, which is less dense than cool air, rises in cooler air. Propane burners are used to heat the air in the balloon; as the temperature of the air increases, so does its volume. The hot gas inflates the balloon and, since the increased volume results in less mass of air per unit volume, the balloon lifts. This relationship between the volume and temperature of a gas is important not only to hot air balloon operators, but also to scuba divers and bread bakers, and is at work during the inflation of a car's air bag, during the operation of a car engine, and in numerous other real-life applications. In this chapter and its companion, Chapter 12, we examine the physical states of matter and their interrelations. Here, we highlight the gaseous state, the one we understand best.

Gases are everywhere. Our atmosphere is a colorless, odorless mixture of 18 gases, some of which— O_2 , N_2 , H_2O vapor, and CO_2 —take part in life-sustaining cycles of redox reactions throughout the environment. Several other gases, such as chlorine and ammonia, have essential roles in industry. Greenhouse gases such as CO_2 and CH_4 are factors in global warming, and we depend on a layer of gaseous ozone, O_3 , to block harmful UV radiation. Yet, in this chapter, we put aside the *chemical* behavior unique to any particular gas and focus instead on the **physical** behavior common to all gases.

IN THIS CHAPTER . . . We explore the physical behavior of gases and the theory that explains it. In the process, we see how scientists use mathematics to model nature.

- › We compare the behaviors of gases, liquids, and solids.
- › We discuss laboratory methods for measuring gas pressure.
- › We consider laws that describe the behavior of a gas in terms of how its volume changes with a change in (1) pressure, (2) temperature, or (3) amount. We focus on the ideal gas law, which encompasses these three laws, and apply it to solve gas law problems.
- › We rearrange the ideal gas law to determine the density and molar mass of an unknown gas, the partial pressure of any gas in a mixture, and the amounts of gaseous reactants and products in a chemical change.
- › We see how the kinetic-molecular theory explains the gas laws and accounts for other important behaviors of gas particles.
- › We apply key ideas about gas behavior to Earth's atmosphere.
- › We find that the behavior of real, not ideal, gases, especially under extreme conditions, requires refinements of the ideal gas law and the kinetic-molecular theory.

5.1 AN OVERVIEW OF THE PHYSICAL STATES OF MATTER

Most substances can exist as a solid, a liquid, or a gas under appropriate conditions of pressure and temperature. In Chapter 1, we used the relative position and motion of the particles of a substance to distinguish how each state fills a container, as illustrated in Figure 5.1 for the three states of bromine:

- A gas adopts the container shape and fills it, because its particles are far apart and move randomly.
- A liquid takes the shape, but not the volume, of its container, because its particles stay close together but are free to move around each other.
- A solid has a fixed shape regardless of the container shape, because its particles are close together and held rigidly in place.

Figure 5.1 The three states of matter. Many pure substances, such as bromine (Br_2), can exist under appropriate conditions of pressure and temperature as a gas, liquid, or solid.

Source: A–C: Stephen Frisch/McGraw Hill

Figure 5.2 Changes in gas volume. A, With pressure. B, With temperature.

Several other aspects of their behaviors distinguish gases from liquids and solids:

1. *Gas volume changes significantly with pressure.* When a sample of gas is confined to a container of variable volume, such as a cylinder with a piston, *increasing* the force on the piston *decreases* the gas volume (Figure 5.2A); thus, gases are compressible—the gas particles can be forced closer together into a smaller volume. Removing the external force allows the volume to increase again. Gases under pressure can do a lot of work: rapidly expanding compressed air in a jackhammer breaks rock and cement; compressed air in tires lifts the weight of a car. In contrast, liquids and solids exhibit very little or no compressibility; the volume of a liquid or a solid does not change significantly under pressure.
2. *Gas volume changes significantly with temperature.* When a sample of gas is heated, it expands (Figure 5.2B); when it is cooled, it shrinks. This volume change is 50 to 100 times greater for gases than for liquids or solids. The expansion that occurs when gases are rapidly heated can have dramatic effects, like lifting a rocket into space, and everyday ones, like popping corn.
3. *Gases flow very freely.* Gases flow much more freely than liquids and solids. This behavior allows gases to be transported more easily through pipes, but it also means they leak more rapidly out of small holes and cracks.
4. *Gases have relatively low densities.* Gas density is usually measured in units of grams per liter (g/L), whereas liquid and solid densities are in grams per milliliter (g/mL), about 1000 times as dense (see Table 1.7). For example, the table in the margin compares the density values of a gas, liquid, and solid at 20°C and normal atmospheric pressure. When a gas cools, its density *increases* because its volume *decreases*: on cooling from 20°C to 0°C, the density of $\text{O}_2(\text{g})$ increases from 1.3 to 1.4 g/L.
5. *Gases form a solution in any proportions.* Air is a solution of 18 gases. Two liquids, however, may or may not form a solution: water and ethanol do, but water and gasoline do not. Two solids generally do not form a solution unless they are melted and mixed while liquids, then allowed to solidify (as is done to make the alloy bronze from copper and tin).

Density*	
$\text{O}_2(\text{g})$	1.3 g/L or 0.0013 g/mL
$\text{H}_2\text{O}(\text{l})$	1.0 g/mL
$\text{NaCl}(\text{s})$	2.2 g/mL

*At 20°C and normal atmospheric pressure.

Like the way a gas completely fills a container, these macroscopic properties—changing volume with pressure or temperature, great ability to flow, low density, and ability to form solutions—arise because the particles in a gas are much farther apart than those in either a liquid or a solid at ordinary pressures.

› Summary of Section 5.1

- › The volume of a gas can be altered significantly by changing the applied force or the temperature. Corresponding changes for liquids and solids are *much* smaller.
- › Gases flow more freely and have much lower densities than liquids and solids.
- › Gases mix in any proportions to form solutions; liquids and solids generally do not.
- › Differences in the physical states are due to the greater average distance between particles in a gas than in a liquid or a solid.

5.2 GAS PRESSURE AND ITS MEASUREMENT

Gas particles move randomly within a container with relatively high velocities, colliding frequently with the container's walls. The force of these collisions with the walls, called the *pressure* of the gas, is the reason you can blow up a balloon or pump up a tire. **Pressure (*P*)** is defined as the force exerted per unit of surface area:

$$\text{Pressure} = \frac{\text{force}}{\text{area}}$$

The gases in the atmosphere exert a force (or *weight*) uniformly on *all* surfaces; the resulting pressure is called *atmospheric pressure* and is typically about 14.7 pounds per square inch (lb/in²; psi) of surface. Thus, a pressure of 14.7 lb/in² exists on the outside of your room (or your body), and it equals the pressure on the inside.

What would happen if the inside and outside pressures on a container were *not* equal? Consider the empty can attached to a vacuum pump in Figure 5.3. With the pump off (*left*), the can maintains its shape because the pressure caused by gas particles in the room colliding with the outside walls of the can is equal to the pressure caused by gas particles in the can colliding with the inside walls. When the pump is turned on (*right*), it removes much of the air inside the can; fewer gas particles inside the can mean fewer collisions with its inside walls, decreasing the internal pressure greatly. The external pressure of the atmosphere then easily crushes the can. Vacuum-filtration flasks and tubing used in chemistry labs have thick walls that withstand the relatively higher external pressure.

Measuring Gas Pressure: Barometers and Manometers

The **barometer** is used to measure atmospheric pressure. The device works as follows:

- A tube about 1 m long, closed at one end, is filled with mercury (atomic symbol Hg), and inverted into a dish containing more mercury.

Figure 5.3 Effect of atmospheric pressure on a familiar object.

Source: A–B: Charles D. Winters/
Timeframe Photography/McGraw Hill

Figure 5.4 A mercury barometer. The pressure of the atmosphere, P_{atm} , balances the pressure of the mercury column, P_{Hg} .

- When the tube is inverted, some of the mercury flows out into the dish, and a vacuum forms above the mercury remaining in the tube (Figure 5.4). The mercury stops flowing out when *the column of mercury in the tube exerts the same pressure (weight/area) on the mercury surface in the dish as the atmosphere does*: $P_{\text{Hg}} = P_{\text{atm}}$. At sea level, under normal conditions, the mercury stops flowing out when the surface of the mercury in the tube is about 760 mm above the surface of the mercury in the dish. (If you evacuate a closed tube and invert it into a dish of mercury, the atmosphere pushes the mercury up to a height of about 760 mm.)
- The diameter of the tube does not affect the height of the mercury column. If the mercury in a 1-cm-diameter tube rises to a height of 760 mm, the mercury in a 2-cm-diameter tube will rise to that height also. The *weight* of mercury is greater in the wider tube, but so is the area; thus, the *pressure*, the *ratio* of weight to area, is the same.

Because the pressure of the mercury column is directly proportional to its height, a unit commonly used for pressure is millimeters of mercury (mmHg). We discuss other units of pressure shortly. *At sea level and 0°C, normal atmospheric pressure is 760 mmHg*; at the top of Mt. Everest (elevation 29,028 ft, or 8848 m), the atmospheric pressure is only about 270 mmHg. Thus, *pressure decreases with altitude*: the column of air above the sea is taller, so it weighs more than the column of air above Mt. Everest.

Laboratory barometers contain mercury because its high density (13.6 g/mL) allows a barometer to be a convenient size. If a barometer contained water ($d = 1.0$ g/mL) instead, it would have to be more than 34 ft high, because the pressure of the atmosphere equals the pressure of a column of water whose height is about $13.6 \times 760 \text{ mm} = 10,300 \text{ mm}$ (almost 34 ft). For a given pressure, the ratio of heights (h) of the liquid columns is inversely related to the ratio of the densities (d) of the liquids:

$$\frac{h_{\text{H}_2\text{O}}}{h_{\text{Hg}}} = \frac{d_{\text{Hg}}}{d_{\text{H}_2\text{O}}}$$

Interestingly, several centuries ago, people thought a vacuum had mysterious “suction” powers, and they didn’t understand why a suction pump could remove water from a well only to a depth of 34 feet. We know now that a vacuum does not suck mercury up into a barometer tube, a suction pump does not suck water up from a well, the vacuum you create in a straw does not suck the drink into your mouth, and the vacuum pump in Figure 5.3 does not suck in the walls of the crushed can. Instead, the atmospheric gases exert a force, pushing the mercury up into the tube, the water up from the well, and the drink up into the straw, as well as crushing the can.

Manometers are devices used to measure the pressure of a gas in an experiment. Figure 5.5 shows two types of manometers, described below.

In the *closed-end manometer*:

- A mercury-filled, curved tube is *closed* at one end and attached to a flask at the other.
- When there is no gas in the flask, the mercury levels in the two arms of the tube are the same, because no gas exerts pressure on either mercury surface.
- When a gas is in the flask, it pushes down the mercury level in the near arm, causing the level to rise in the far arm.
- The *difference* in column heights (Δh) equals the gas pressure: $\Delta h = P_{\text{gas}}$.

In *open-end manometer*:

- A mercury-filled, curved tube is *open* at one end and attached to a flask at the other.
- The atmosphere pushes on one mercury surface, and the gas in the flask pushes on the other. Δh equals the *difference* between the gas pressure and the atmospheric pressure.
- We must measure the atmospheric pressure with a barometer and either add or subtract Δh from that value to obtain the gas pressure, as shown in Figure 5.5.

The device used to measure blood pressure is based on a manometer apparatus.

Figure 5.5 Two types of manometer.

Units of Pressure

Pressure results from a force exerted on an area. The SI unit of force is the newton (N): $1 \text{ N} = 1 \text{ kg} \cdot \text{m/s}^2$ (about the weight of an apple). The SI unit of pressure is the **pascal (Pa)**, which equals a force of 1 newton exerted on an area of 1 square meter:

$$1 \text{ Pa} = 1 \text{ N/m}^2$$

A much larger unit is the **standard atmosphere (atm)**, the average atmospheric pressure measured at sea level and 0°C . It is defined in terms of the pascal:

$$1 \text{ atm} = 101.325 \text{ kilopascals (kPa)} = 1.01325 \times 10^5 \text{ Pa}$$

Another common unit is the **millimeter of mercury (mmHg)**, mentioned earlier; in honor of the Italian physicist Evangelista Torricelli, this unit has been renamed the **torr**:

$$1 \text{ torr} = 1 \text{ mmHg} = \frac{1}{760} \text{ atm} = \frac{101.325}{760} \text{ kPa} = 133.322 \text{ Pa}$$

The *bar* is coming into more common use in chemistry:

$$1 \text{ bar} = 1 \times 10^2 \text{ kPa} = 1 \times 10^5 \text{ Pa}$$

Despite a gradual change to SI units, many chemists still express pressure in torrs and atmospheres, so those units are used in this book, with reference to pascals and bars. Table 5.1 lists some important pressure units with the corresponding values for normal atmospheric pressure.

Table 5.1 | Common Units of Pressure

Unit	Normal Atmospheric Pressure at Sea Level and 0°C
pascal (Pa); kilopascal (kPa)	$1.01325 \times 10^5 \text{ Pa}$; 101.325 kPa
atmosphere (atm)	1 atm*
millimeters of mercury (mmHg)	760 mmHg*
torr	760 torr*
pounds per square inch (lb/in ² or psi)	14.696 lb/in ²
bar	1.01325 bar

*These are exact quantities; in calculations, we use as many significant figures as necessary.

SAMPLE PROBLEM 5.1 | Converting Units of Pressure

Problem A geochemist heats a sample of limestone (CaCO_3) and collects the CO_2 released in an evacuated flask attached to a closed-end manometer. After the system comes to room temperature, $\Delta h = 291.4 \text{ mmHg}$. Calculate the CO_2 pressure in torrs, atmospheres, and kilopascals.

Plan In a closed-end manometer, $P_{\text{gas}} = \Delta h$, so $P_{\text{CO}_2} = 291.4 \text{ mmHg}$. We construct conversion factors from Table 5.1 to find the pressure in the other units.

Solution Converting from mmHg to torr:

$$P_{\text{CO}_2} (\text{torr}) = 291.4 \text{ mmHg} \times \frac{1 \text{ torr}}{1 \text{ mmHg}} = 291.4 \text{ torr}$$

Converting from torr to atm:

$$P_{\text{CO}_2} (\text{atm}) = 291.4 \text{ torr} \times \frac{1 \text{ atm}}{760 \text{ torr}} = 0.3834 \text{ atm}$$

Converting from atm to kPa:

$$P_{\text{CO}_2} (\text{kPa}) = 0.3834 \text{ atm} \times \frac{101.325 \text{ kPa}}{1 \text{ atm}} = 38.85 \text{ kPa}$$

Check There are 760 torr in 1 atm, so ~ 300 torr should be < 0.5 atm. There are ~ 100 kPa in 1 atm, so < 0.5 atm should be < 50 kPa.

Comment 1. In the conversion from torr to atm, we retained four significant figures because this unit conversion factor involves *exact* numbers; that is, 760 torr has as many significant figures as the calculation requires (see the footnote to Table 5.1). **2.** From here on, except in particularly complex situations, *unit canceling will no longer be shown*.

FOLLOW-UP PROBLEMS

Brief Solutions to all Follow-up Problems appear at the end of the chapter.

5.1A The CO_2 released from another limestone sample is collected in an evacuated flask connected to an open-end manometer. If the barometer reading is 753.6 mmHg and P_{gas} is less than P_{atm} , giving $\Delta h = 174.0 \text{ mmHg}$, calculate P_{CO_2} in torrs, pascals, and lb/in^2 .

5.1B A third sample of limestone is heated, and the CO_2 released is collected in an evacuated flask connected to an open-end manometer. If the atmospheric pressure is 0.9475 atm and P_{gas} is greater than P_{atm} , giving $\Delta h = 25.8 \text{ torr}$, calculate P_{CO_2} in mmHg, pascals, and lb/in^2 .

SOME SIMILAR PROBLEMS 5.8–5.13

› Summary of Section 5.2

- › Gases exert pressure (force/area) on all surfaces they contact.
- › A barometer measures atmospheric pressure based on the height of a mercury column that the atmosphere can support (760 mmHg at sea level and 0°C).
- › Closed-end and open-end manometers are used to measure the pressure of a gas sample.
- › Pressure units include the atmosphere (atm), torr (identical to mmHg), and pascal (Pa, the SI unit).

5.3

THE GAS LAWS AND THEIR EXPERIMENTAL FOUNDATIONS

The physical behavior of a sample of gas can be described completely by four variables: pressure (P), volume (V), temperature (T), and amount (number of moles, n). The variables are interdependent, which means that *any one of them can be determined by measuring the other three*. Three key relationships exist among the four gas

variables—Boyle’s, Charles’s, and Avogadro’s laws. Each of these *gas laws expresses the effect of one variable on another, with the remaining two variables held constant*. Because gas volume is so easy to measure, the laws are expressed as the effect on gas volume of a change in the pressure, temperature, or amount of the gas.

The gas laws quantitatively describe the behavior of an **ideal gas**, one that exhibits linear relationships among volume, pressure, temperature, and amount. Although *no ideal gas actually exists*, most simple gases, such as N_2 , O_2 , H_2 , and the noble gases, behave nearly ideally at ordinary temperatures and pressures.

The Relationship Between Volume and Pressure: Boyle’s Law

The 17th-century English chemist Robert Boyle studied the effect of pressure on the volume of a sample of gas.

1. *The experiment.* Figure 5.6 (parts A and B) illustrates the setup Boyle might have used in his experiments to measure the effect of the applied pressure on gas volume while keeping the temperature and amount of gas constant:

- Mercury was poured into the longer, open leg of a J-shaped glass tube, trapping some air (the gas in the experiment) in the sealed, shorter leg of the tube. The volume of the air (V_{gas}) was calculated from the height, h , of the trapped air column and the diameter of the tube ($V = \pi r^2 h$, where r = radius of the tube).
- The total pressure, P_{total} , applied to the trapped gas is the pressure of the atmosphere, P_{atm} (760 mm, measured with a barometer), plus the difference in the heights of the mercury columns (Δh) in the two legs of the J tube.
- Figure 5.6A shows that when enough mercury has been poured into the tube to cause a P_{total} of 780 torr, V_{gas} is 20 mL. In Figure 5.6B, enough mercury has been poured into the tube to *double* P_{total} to 1560 torr and the result is that V_{gas} has been *halved* from 20 mL to 10 mL.
- The data collected from this experiment shows that the product of the corresponding P and V values is a constant (Figure 5.6C, *rightmost column*).
- The graph in Figure 5.6D shows that V is *inversely* proportional to P —the greater the pressure, the smaller the gas volume.
- As shown in Figure 5.6E, V is *directly* proportional to $1/P$, and a plot of V versus $1/P$ is linear.

Figure 5.6 Boyle’s law, the relationship between the volume and pressure of a gas.

2. *Conclusion and statement of the law.* The generalization of Boyle's observations is known as

- **Boyle's law:** *at constant temperature, the volume occupied by a fixed amount of gas is **inversely** proportional to the applied (external) pressure, or*

$$V \propto \frac{1}{P} \quad [T \text{ and } n \text{ fixed}] \quad (5.1)$$

This relationship can also be expressed as

$$V = \frac{\text{constant}}{P} \quad \text{or} \quad PV = \text{constant} \quad [T \text{ and } n \text{ fixed}]$$

That is, at fixed T and n , $P \uparrow, V \downarrow$ and $P \downarrow, V \uparrow$

The constant is the same for most simple gases under ordinary conditions. Thus, tripling the external pressure reduces the volume of a gas to a third of its initial value; halving the pressure doubles the volume; and so forth.

The wording of Boyle's law focuses on *external* pressure. But, notice that the mercury level rises as mercury is added, until the pressure of the trapped gas *on* the mercury increases enough to stop its rise. At that point, the pressure exerted *on* the gas equals the pressure exerted *by* the gas (P_{gas}). Thus, in general, at constant temperature, if V_{gas} increases, P_{gas} decreases, and vice versa.

The Relationship Between Volume and Temperature: Charles's Law

French scientists J. A. C. Charles and J. L. Gay-Lussac examined the relationship between gas volume and temperature.

1. *The experiment.* Let's examine this relationship by measuring the volume at different temperatures of a fixed amount of gas under constant pressure:

- A straight tube, closed at one end, traps a fixed amount of gas (air) under a small mercury plug. The tube is immersed in a water bath that is warmed with a heater or cooled with ice (Figure 5.7, parts A and B).

Figure 5.7 Charles's law, the relationship between the volume and temperature of a gas.

- After each change of temperature, we calculate the gas volume from the length of the gas column and the diameter of the tube. The total pressure exerted on the gas is constant because the mercury plug and the atmospheric pressure do not change.
- The collected data for a 0.04-mol sample of gas at 1 atm show that dividing the volume of gas by the corresponding Kelvin temperature results in a constant (Figure 5.7C, *rightmost column*).
- V is *directly* proportional to T in kelvins (*red line* in Figure 5.7D)—the higher the temperature, the larger the gas volume.
- There is a *linear relationship between V and T* .
- Extrapolating the red line in the graph in Figure 5.7D to lower temperatures (*dashed portion*) shows that, in theory, the gas occupies zero volume at -273.15°C (the intercept on the temperature axis).
- Plots for a different amount of gas (*green line* in Figure 5.7D) or for a different gas pressure (*blue line*) have different slopes, but they converge at -273.15°C .

2. *Conclusion and statement of the law.* Unlike volume and pressure, volume and temperature are *directly* proportional. This behavior is incorporated into the modern statement of the volume-temperature relationship:

- **Charles's law:** *at constant pressure, the volume occupied by a fixed amount of gas is **directly** proportional to its absolute (Kelvin) temperature, or*

$$V \propto T \quad [P \text{ and } n \text{ fixed}] \quad (5.2)$$

This relationship can also be expressed as

$$V = \text{constant} \times T \quad \text{or} \quad \frac{V}{T} = \text{constant} \quad [P \text{ and } n \text{ fixed}]$$

That is, at fixed P and n , $T \uparrow$, $V \uparrow$ and $T \downarrow$, $V \downarrow$

If T increases by some factor, V increases by the same factor, and vice versa. As with Boyle's law, the constant is the same for most simple gases under ordinary conditions and for any given P and n .

Figure 5.7D shows that absolute zero (0 K, or -273.15°C) is the temperature at which an ideal gas would have zero volume. (Absolute zero has never been reached, but physicists have attained 10^{-9} K.) In reality, no sample of matter can have zero volume, and every real gas condenses to a liquid at some temperature higher than 0 K, but the linear dependence of volume on absolute temperature holds for most common gases over a wide temperature range. Because the volume of gas is only directly proportional to Kelvin temperature, *the Kelvin scale must be used in gas law calculations*. For instance, if the temperature changes from 200 K to 400 K, the volume of gas doubles because the absolute temperature doubles. But, if the temperature doubles from 200°C to 400°C , the volume increases by a factor of 1.42, not by a factor of 2; that is,

$$\left(\frac{400^\circ\text{C} + 273.15}{200^\circ\text{C} + 273.15} \right) = \frac{673 \text{ K}}{473 \text{ K}} = 1.42$$

Other Relationships Based on Boyle's and Charles's Laws Two other important relationships arise from Boyle's and Charles's laws:

1. *The pressure-temperature relationship.* Charles's law is expressed as the effect of temperature on gas *volume* at constant pressure. But volume and pressure are interdependent, so a similar relationship can be expressed for the effect of temperature on pressure (sometimes referred to as *Amontons's law*):

- *At constant volume, the pressure exerted by a fixed amount of gas is directly proportional to the absolute temperature, or*

$$P \propto T \quad [V \text{ and } n \text{ fixed}] \quad (5.3)$$

or

$$P = \text{constant} \times T \quad \text{or} \quad \frac{P}{T} = \text{constant} \quad [V \text{ and } n \text{ fixed}]$$

That is, at fixed V and n , $T \uparrow, P \uparrow$ and $T \downarrow, P \downarrow$

If T increases, V increases, and vice versa.

You can examine this relationship for yourself: measure the pressure in your car or bike tires before and after a long ride and you will find that the air pressure in the tires increases. The air temperature inside the tires also increases from heating due to friction between the tires and the road; a tire's volume can't increase very much, but the increased temperature results in increased pressure.

2. *The combined gas law.* Combining Boyle's and Charles's laws gives the *combined gas law*, which applies to cases when changes in *two* of the three variables (V, P, T) affect the third:

$$\text{Boyle's law: } V \propto \frac{1}{P}; \text{ Charles's law: } V \propto T$$

$$\text{Combined gas law: } V \propto \frac{T}{P} \quad \text{or} \quad V = \text{constant} \times \frac{T}{P} \quad \text{or} \quad \frac{PV}{T} = \text{constant}$$

The Relationship Between Volume and Amount: Avogadro's Law

So far we have examined the relationship between the volume, pressure, and temperature of a fixed amount of gas. Now let's see what happens to the gas volume when we vary the amount of gas.

1. *The experiment.* Figure 5.8 shows an experiment that involves two small test tubes, each fitted to a much larger piston-cylinder assembly. We add 0.10 mol (4.4 g) of dry ice (solid CO_2) to the first tube (A) and 0.20 mol (8.8 g) to the second tube (B). As the solid CO_2 warms to room temperature, it changes to gaseous CO_2 , and the volume increases until $P_{\text{gas}} = P_{\text{atm}}$. At constant temperature, when all the solid has changed to gas, cylinder B, with twice the amount of CO_2 , has twice the volume of cylinder A.

2. *Conclusion and statement of the law.* This behavior illustrates the relationship between volume and amount of gas:

- **Avogadro's law:** at fixed temperature and pressure, the volume occupied by a gas is directly proportional to the amount (mol) of gas, or

$$V \propto n \quad [P \text{ and } T \text{ fixed}] \quad (5.4)$$

That is, as n increases, V increases, and vice versa. This relationship is also expressed as

$$V = \text{constant} \times n \quad \text{or} \quad \frac{V}{n} = \text{constant} \quad [P \text{ and } T \text{ fixed}]$$

That is, at fixed P and T , $n \uparrow, V \uparrow$ and $n \downarrow, V \downarrow$

The constant is the same for all simple gases at ordinary temperature and pressure. Avogadro's law indicates that, *at fixed temperature and pressure, equal volumes of any ideal gas contain equal numbers (or moles) of particles.*

Figure 5.8 Avogadro's law, the relationship between the volume and amount of a gas.

Familiar Applications of the Gas Laws The gas laws apply to countless familiar phenomena:

- In a car engine, a reaction occurs in which fewer moles of gasoline and O_2 form more moles of CO_2 and H_2O vapor, and heat is released. The increase in n (Avogadro's law) and T (Charles's law) increases V , and the pistons in the engine are pushed back.
- Dynamite is a solid that forms more moles of hot gases very rapidly when it reacts (Avogadro's law); the hot gases expand (Charles's laws) and apply pressure.
- Dough rises because yeast digests sugar, which creates bubbles of CO_2 (Avogadro's law); the dough expands more as the bread bakes in a hot oven (Charles's law).
- The process of breathing is a familiar application of the gas laws (Figure 5.9). When you inhale, muscles move your diaphragm down and your rib cage out (*blue*). This coordinated movement increases the volume of your lungs, which decreases the air pressure inside them (Boyle's law). The inside pressure is 1–3 torr *less* than atmospheric pressure, so air rushes in. The greater amount of air stretches the elastic tissue of the lungs and expands the volume further (Avogadro's law). The air also expands as it warms from the external temperature to your body temperature (Charles's law). When you exhale, the diaphragm moves up and the rib cage moves in, so your lung volume decreases (*red*). The inside pressure becomes 1–3 torr *more* than the outside pressure (Boyle's law), so air rushes out.

Figure 5.9 The process of breathing applies the gas laws.

Gas Behavior at Standard Conditions

To better understand the factors that influence gas behavior, chemists have assigned a baseline set of *standard conditions* called **standard temperature and pressure (STP)**:

$$\text{STP: } 0^\circ\text{C (273.15 K) and 1 atm (760 torr)} \quad (5.5)$$

Under these conditions of temperature and pressure, the volume of 1 mol of an ideal gas is called the **standard molar volume**:

$$\text{Standard molar volume} = 22.41395 \text{ L or } 22.4 \text{ L [to 3 sf]} \quad (5.6)$$

At STP, helium, nitrogen, oxygen, and other simple gases behave nearly ideally (Figure 5.10). Note that the mass, and thus the density (d), depends on the specific gas, but 1 mol of any of them occupies 22.4 L at STP.

Figure 5.11 compares the volumes of some familiar objects with the standard molar volume of an ideal gas.

		
$n = 1 \text{ mol}$	$n = 1 \text{ mol}$	$n = 1 \text{ mol}$
$P = 1 \text{ atm (760 torr)}$	$P = 1 \text{ atm (760 torr)}$	$P = 1 \text{ atm (760 torr)}$
$T = 0^\circ\text{C (273 K)}$	$T = 0^\circ\text{C (273 K)}$	$T = 0^\circ\text{C (273 K)}$
$V = 22.4 \text{ L}$	$V = 22.4 \text{ L}$	$V = 22.4 \text{ L}$
Number of gas particles $= 6.022 \times 10^{23}$	Number of gas particles $= 6.022 \times 10^{23}$	Number of gas particles $= 6.022 \times 10^{23}$
Mass = 4.003 g	Mass = 28.02 g	Mass = 32.00 g
$d = 0.179 \text{ g/L}$	$d = 1.25 \text{ g/L}$	$d = 1.43 \text{ g/L}$

Figure 5.10 Standard molar volume. One mole of an ideal gas occupies 22.4 L at STP (0°C and 1 atm).

Figure 5.11 The volumes of 1 mol (22.4 L) of an ideal gas and of some familiar objects: 1 gal of milk (3.79 L), a basketball (7.50 L), and 2.00 L of a carbonated drink.

Source: Charles D. Winters/McGraw Hill

The Ideal Gas Law

Each of the three gas laws shows how one of the other three gas variables affects gas volume:

- Boyle's law focuses on pressure ($V \propto 1/P$).
- Charles's law focuses on temperature ($V \propto T$).
- Avogadro's law focuses on amount (mol) of gas ($V \propto n$).

By combining these individual effects, we obtain the **ideal gas law** (or *ideal gas equation*):

$$V \propto \frac{nT}{P} \quad \text{or} \quad PV \propto nT \quad \text{or} \quad PV = \text{constant} \times nT \quad \text{or} \quad \frac{PV}{nT} = R$$

where **R** is a proportionality constant known as the **universal gas constant**. Rearranging gives the most common form of the ideal gas law:

$$PV = nRT \quad (5.7)$$

We obtain a value of R by measuring the volume, temperature, and pressure of a given amount of gas and substituting the values into the ideal gas law. For example, using STP conditions for the gas variables and 1 mol of gas, we have

$$R = \frac{PV}{nT} = \frac{1 \text{ atm} \times 22.41395 \text{ L}}{1 \text{ mol} \times 273.15 \text{ K}} = 0.0820573 \frac{\text{atm} \cdot \text{L}}{\text{mol} \cdot \text{K}} = 0.0821 \frac{\text{atm} \cdot \text{L}}{\text{mol} \cdot \text{K}} [3 \text{ sf}] \quad (5.8)$$

This numerical value of R corresponds to P , V , and T expressed in these units; R has a different numerical value when different units are used. For example, in the equation for root-mean-square speed in Section 5.5, R has the value $8.314 \text{ J/mol} \cdot \text{K}$ (J stands for joule, the SI unit of energy).

As shown in Figure 5.12, the ideal gas law *becomes* one of the individual gas laws when two of the four variables are kept constant. When initial conditions (subscript “1”) change to final conditions (subscript “2”), we have

$$P_1V_1 = n_1RT_1 \quad \text{and} \quad P_2V_2 = n_2RT_2$$

Thus,

$$\frac{P_1V_1}{n_1T_1} = R \quad \text{and} \quad \frac{P_2V_2}{n_2T_2} = R, \quad \text{so} \quad \frac{P_1V_1}{n_1T_1} = \frac{P_2V_2}{n_2T_2}$$

Notice that, if, for example, the two variables P and T remain constant, then $P_1 = P_2$ and $T_1 = T_2$, and we obtain an expression for Avogadro's law:

$$\frac{\cancel{P_1}V_1}{n_1\cancel{T_1}} = \frac{\cancel{P_2}V_2}{n_2\cancel{T_2}} \quad \text{or} \quad \frac{V_1}{n_1} = \frac{V_2}{n_2}$$

As you'll see next, you can use a similar approach to solve gas law problems. Thus, by keeping track of the initial and final values of the gas variables, you avoid the need to memorize the three individual gas laws.

Figure 5.12 The individual gas laws as special cases of the ideal gas law.

Solving Gas Law Problems

Gas law problems are phrased in many ways but can usually be grouped into two types:

1. *There is a change in one of the four variables, which causes a change in another while the two other variables remain constant.* In this type, the ideal gas law reduces to one of the individual gas laws when you omit the variables that remain constant; you then solve for the new value of the affected variable. Units must be consistent and T must always be in kelvins, but R is not involved. Sample Problems 5.2 to 5.4 are of this type. A variation on this type, shown in Sample Problem 5.5, involves the combined gas law when simultaneous changes in two of the variables cause a change in a third.

2. *One variable is unknown, but the other three are known, as is R , and no change occurs.* In this type, exemplified by Sample Problem 5.6, you apply the ideal gas law directly to find the unknown, and the units must conform to those in R .

Solving these problems requires a systematic approach:

- Summarize the changing gas variables—knowns and unknown—and those held constant.
- Convert units, if necessary.
- Rearrange the ideal gas law to obtain the needed relationship of variables, and solve for the unknown.

SAMPLE PROBLEM 5.2 | Applying the Volume-Pressure Relationship

Problem A 3.50-L sample of neon gas has a pressure of 924 torr. What pressure (in atm) is required to compress the gas into a tank with a volume of 1350 cm³ at constant temperature?

Plan We must find the final pressure (P_2) in atm, given the initial volume (V_1), initial pressure (P_1), and final volume (V_2). The temperature and amount of gas are fixed. We must use consistent units of volume, so we convert the unit of V_2 from cm³ to mL and then to L. We then convert the unit of P_1 from torr to atm, rearrange the ideal gas law to the appropriate form, and solve for P_2 . (Note that the road map has two parts, unit conversion and the gas law calculation.)

Solution Summarizing the gas variables:

$P_1 = 924$ torr (convert to atm) $P_2 = \text{unknown}$

$V_1 = 3.50$ L $V_2 = 1350$ cm³ (convert to L)

T and n remain constant

Converting P_1 from torr to atm:

$$P_1 (\text{atm}) = 924 \text{ torr} \times \frac{1 \text{ atm}}{760 \text{ torr}} = 1.22 \text{ atm}$$

Converting V_2 from cm³ to L:

$$V_2 (\text{L}) = 1350 \text{ cm}^3 \times \frac{1 \text{ mL}}{1 \text{ cm}^3} \times \frac{1 \text{ L}}{1000 \text{ mL}} = 1.35 \text{ L}$$

Rearranging the ideal gas law and solving for P_2 : at fixed n and T , we have

$$\frac{P_1 V_1}{n_1 T_1} = \frac{P_2 V_2}{n_2 T_2} \quad \text{or} \quad P_1 V_1 = P_2 V_2$$

$$P_2 = P_1 \times \frac{V_1}{V_2} = 1.22 \text{ atm} \times \frac{3.50 \text{ L}}{1.35 \text{ L}} = 3.16 \text{ atm}$$

Check The relative values of P and V can help us check the math: V_2 is less than $\frac{1}{2} V_1$, so P_2 should be more than $2P_1$ ($3.16/1.22 > 2$).

Comment 1. Predicting the direction of the change provides another check on the problem setup: since V decreases, P will increase; thus, P_2 should be more than P_1 . To make $P_2 > P_1$, we must multiply P_1 by a number *greater than 1*. This means the ratio of volumes must be *greater than 1*, so the larger volume (V_1) must be in the numerator, or V_1/V_2 . **2.** Since R was not involved in this problem, any unit of volume can be used,

Road Map

as long as the same unit is used for both V_1 and V_2 . We used L, but we could have used cm^3 instead; however, both L and cm^3 cannot be used.

FOLLOW-UP PROBLEMS

5.2A A tank contains 651 L of compressed oxygen gas at a pressure of 122 atm. Assuming the temperature remains constant, what is the volume of the oxygen (in L) at 745 mmHg?

5.2B A sample of argon gas occupies 105 mL at 0.871 atm. If the volume of the gas is increased to 352 mL at constant temperature, what is the final pressure of the gas (in kPa)?

SOME SIMILAR PROBLEMS 5.24 and 5.25

SAMPLE PROBLEM 5.3

Applying the Volume-Temperature and Pressure-Temperature Relationships

Problem A balloon is filled with 1.95 L of air at 25°C and then placed in a car sitting in the sun. What is the volume of the balloon when the temperature in the car reaches 90°C ?

Plan We know the initial volume (V_1) and the initial (T_1) and final (T_2) temperatures of the gas; we must find the final volume (V_2). The pressure of the gas is fixed, since the balloon is subjected to atmospheric pressure, and n is fixed, since air cannot escape or enter the balloon. We convert both T values to kelvins, rearrange the ideal gas law, and solve for V_2 (see the road map).

Solution Summarizing the gas variables:

$$\begin{array}{ll} V_1 = 1.95 \text{ L} & V_2 = \text{unknown} \\ T_1 = 25^\circ\text{C} \text{ (convert to K)} & T_2 = 90^\circ\text{C} \text{ (convert to K)} \\ P \text{ and } n \text{ remain constant} & \end{array}$$

Converting T from $^\circ\text{C}$ to K:

$$T_1 (\text{K}) = 25^\circ\text{C} + 273.15 = 298 \text{ K} \quad T_2 (\text{K}) = 90^\circ\text{C} + 273.15 = 363 \text{ K}$$

Rearranging the ideal gas law and solving for V_2 : at fixed n and P , we have

$$\frac{P_1 V_1}{n_1 T_1} = \frac{P_2 V_2}{n_2 T_2} \quad \text{or} \quad \frac{V_1}{T_1} = \frac{V_2}{T_2}$$

$$V_2 = V_1 \times \frac{T_2}{T_1} = 1.95 \text{ L} \times \frac{363 \text{ K}}{298 \text{ K}} = 2.38 \text{ L}$$

Check Let's predict the change to check the math: because $T_2 > T_1$, we expect $V_2 > V_1$. Thus, the temperature ratio should be greater than 1 (T_2 in the numerator). The T ratio is about 1.2 ($363/298$), so the V ratio should also be about 1.2 ($2.38/1.95 \approx 1.2$).

FOLLOW-UP PROBLEMS

5.3A A steel tank used for fuel delivery is fitted with a safety valve that opens if the internal pressure exceeds 1.00×10^3 torr. The tank is filled with methane at 23°C and 0.991 atm and placed in boiling water at 100°C . What is the pressure in the heated tank? Will the safety valve open?

5.3B A sample of nitrogen occupies a volume of 32.5 L at 40°C . Assuming that the pressure remains constant, what temperature (in $^\circ\text{C}$) will result in a decrease in the sample's volume to 28.6 L?

SOME SIMILAR PROBLEMS 5.26–5.29

SAMPLE PROBLEM 5.4

Applying the Volume-Amount and Pressure-Amount Relationships

Problem A scale model of a blimp rises when it is filled with helium to a volume of 55.0 dm^3 . When 1.10 mol of He is added to the blimp, the volume is 26.2 dm^3 . How many more grams of He must be added to make it rise? Assume constant T and P .

Plan We are given the initial amount of helium (n_1), the initial volume of the blimp (V_1), and the volume needed for it to rise (V_2), and we need the additional mass of helium to make it rise. So, we first need to find n_2 . We rearrange the ideal gas law to the appropriate form, solve for n_2 , subtract n_1 to find the additional amount ($n_{\text{add'l}}$), and then convert moles to grams (see the road map).

Road Map

Solution Summarizing the gas variables:

$$\begin{array}{ll} n_1 = 1.10 \text{ mol} & n_2 = \text{unknown (find, and then subtract } n_1) \\ V_1 = 26.2 \text{ dm}^3 & V_2 = 55.0 \text{ dm}^3 \\ P \text{ and } T \text{ remain constant} \end{array}$$

Rearranging the ideal gas law and solving for n_2 : at fixed P and T , we have

$$\frac{P_1 V_1}{n_1 T_1} = \frac{P_2 V_2}{n_2 T_2} \quad \text{or} \quad \frac{V_1}{n_1} = \frac{V_2}{n_2}$$

$$n_2 = n_1 \times \frac{V_2}{V_1} = 1.10 \text{ mol He} \times \frac{55.0 \text{ dm}^3}{26.2 \text{ dm}^3}$$

$$= 2.31 \text{ mol He}$$

Finding the additional amount of He:

$$n_{\text{add'l}} = n_2 - n_1 = 2.31 \text{ mol He} - 1.10 \text{ mol He}$$

$$= 1.21 \text{ mol He}$$

Converting amount (mol) of He to mass (g):

$$\text{Mass (g) of He} = 1.21 \text{ mol He} \times \frac{4.003 \text{ g He}}{1 \text{ mol He}}$$

$$= 4.84 \text{ g He}$$

Check We predict that $n_2 > n_1$ because $V_2 > V_1$: since V_2 is about twice V_1 ($55/26 \approx 2$), n_2 should be about twice n_1 ($2.3/1.1 \approx 2$). Since $n_2 > n_1$, we were right to multiply n_1 by a number greater than 1 (that is, V_2/V_1). About $1.2 \text{ mol} \times 4 \text{ g/mol} \approx 4.8 \text{ g}$.

Comment 1. Because we did not use R , notice that any unit of volume, in this case dm^3 , is acceptable as long as V_1 and V_2 are expressed in the same unit.

2. A different sequence of steps should give you the same answer: first find the additional volume ($V_{\text{add'l}} = V_2 - V_1$), and then solve directly for $n_{\text{add'l}}$. Try it for yourself.

3. You saw that Charles's law ($V \propto T$ at fixed P and n) becomes a similar relationship between P and T at fixed V and n . Follow-up Problem 5.4A demonstrates that Avogadro's law ($V \propto n$ at fixed P and T) becomes a similar relationship at fixed V and T .

FOLLOW-UP PROBLEMS

5.4A A rigid plastic container holds 35.0 g of ethylene gas (C_2H_4) at a pressure of 793 torr. What is the pressure if 5.0 g of ethylene is removed at constant temperature?

5.4B A balloon filled with 1.26 g of nitrogen gas has a volume of 1.12 L. Calculate the volume of the balloon after 1.26 g of helium gas is added while T and P remain constant.

SOME SIMILAR PROBLEMS 5.30 and 5.31

Road Map

SAMPLE PROBLEM 5.5

Applying the Volume-Pressure-Temperature Relationship

Problem A helium-filled balloon has a volume of 15.8 L at a pressure of 0.980 atm and 22°C. What is its volume at the summit of Mt. Hood, Oregon's highest mountain, where the atmospheric pressure is 532 mmHg and the temperature is 0°C?

Plan We know the initial volume (V_1), pressure (P_1), and temperature (T_1) of the gas; we also know the final pressure (P_2) and temperature (T_2), and we must find the final volume (V_2). Since the amount of helium in the balloon does not change, n is fixed. We convert both T values to kelvins, convert the final pressure to atm, rearrange the ideal gas law, and solve for V_2 . This is a combined gas law problem.

Solution Summarizing the gas variables:

$$\begin{array}{ll} V_1 = 15.8 \text{ L} & V_2 = \text{unknown} \\ T_1 = 22^\circ\text{C (convert to K)} & T_2 = 0^\circ\text{C (convert to K)} \\ P_1 = 0.980 \text{ atm} & P_2 = 532 \text{ mmHg (convert to atm)} \\ n \text{ remains constant} \end{array}$$

Converting T from °C to K:

$$T_1 (\text{K}) = 22^\circ\text{C} + 273.15 = 295 \text{ K} \quad T_2 (\text{K}) = 0^\circ\text{C} + 273.15 = 273 \text{ K}$$

Converting P_2 to atm:

$$P_2 \text{ (atm)} = 532 \text{ mmHg} \times \frac{1 \text{ atm}}{760 \text{ mmHg}} = 0.700 \text{ atm}$$

Rearranging the ideal gas law and solving for V_2 : at fixed n , we have

$$\frac{P_1 V_1}{n_1 T_1} = \frac{P_2 V_2}{n_2 T_2} \quad \text{or} \quad \frac{P_1 V_1}{T_1} = \frac{P_2 V_2}{T_2}$$

$$V_2 = V_1 \times \frac{P_1 T_2}{P_2 T_1} = 15.8 \text{ L} \times \frac{(0.980 \text{ atm})(273 \text{ K})}{(0.700 \text{ atm})(295 \text{ K})} = 20.5 \text{ L}$$

Check Let's predict the change to check the math: because $T_2 < T_1$, we expect $V_2 < V_1$; but, because $P_2 < P_1$, we expect $V_2 > V_1$. The temperature ratio (T_2 in the numerator) is about 0.93 (273/295), and the pressure ratio (P_1 in the numerator) is about 1.4 (0.980/0.700), so the V ratio should be about 0.93×1.4 , or 1.3 (20.5/15.8 $\approx$ 1.3). The pressure decreases by a larger factor than the temperature decreases, so there is an overall increase in volume.

FOLLOW-UP PROBLEMS

5.5A A sample of nitrogen gas occupies a volume of 2.55 L at 755 mmHg and 23°C. Its volume increases to 4.10 L, and its temperature decreases to 18°C. What is the final pressure?

5.5B A diver has 2.2 L of air in his lungs at an air temperature of 28°C and a pressure of 0.980 atm. What is the volume of air in his lungs after he dives, while holding his breath, to a depth of 10 m, where the temperature is 21°C and the pressure is 1.40 atm?

SOME SIMILAR PROBLEMS 5.32 and 5.33

SAMPLE PROBLEM 5.6

Solving for an Unknown Gas Variable at Fixed Conditions

Problem A steel tank has a volume of 438 L and is filled with 0.885 kg of O_2 . Calculate the pressure of O_2 at 21°C.

Plan We are given V , T , and the mass of O_2 , and we must find P . Since the conditions are not changing, we apply the ideal gas law without rearranging it. We use the given V in liters, convert T to kelvins and mass (kg) of O_2 to amount (mol), and solve for P .

Solution Summarizing the gas variables:

$$\begin{array}{ll} V = 438 \text{ L} & T = 21^\circ\text{C (convert to K)} \\ n = 0.885 \text{ kg } O_2 \text{ (convert to mol)} & P = \text{unknown} \end{array}$$

Converting T from °C to K:

$$T(\text{K}) = 21^\circ\text{C} + 273.15 = 294 \text{ K}$$

Converting from mass (g) of O_2 to amount (mol):

$$n = \text{mol of } O_2 = 0.885 \text{ kg } O_2 \times \frac{1000 \text{ g}}{1 \text{ kg}} \times \frac{1 \text{ mol } O_2}{32.00 \text{ g } O_2} = 27.7 \text{ mol } O_2$$

Solving for P (note the unit canceling here):

$$\begin{aligned} P &= \frac{nRT}{V} = \frac{27.7 \text{ mol} \times 0.0821 \frac{\text{atm}\cdot\text{L}}{\text{mol}\cdot\text{K}} \times 294 \text{ K}}{438 \text{ L}} \\ &= 1.53 \text{ atm} \end{aligned}$$

Check The amount of O_2 seems correct: $\sim 900 \text{ g} / (30 \text{ g/mol}) = 30 \text{ mol}$. To check the approximate size of the final calculation, round off the values, including that for R :

$$P = \frac{30 \text{ mol } O_2 \times 0.1 \frac{\text{atm}\cdot\text{L}}{\text{mol}\cdot\text{K}} \times 300 \text{ K}}{450 \text{ L}} = 2 \text{ atm}$$

which is reasonably close to 1.53 atm.

FOLLOW-UP PROBLEMS

5.6A The tank in Sample Problem 5.6 develops a slow leak, which is discovered and sealed. The new pressure is 1.37 atm. How many grams of O_2 remain?

5.6B A blimp is filled with 3950 kg of helium at 731 mmHg and 20°C . What is the volume of the blimp under these conditions?

SOME SIMILAR PROBLEMS 5.34–5.37

Finally, in a picture problem, we apply the gas laws to determine the balanced equation for a gaseous reaction.

SAMPLE PROBLEM 5.7

Using Gas Laws to Determine a Balanced Equation

Problem The piston-cylinder below is depicted before and after a gaseous reaction that is carried out in it at constant pressure: the temperature is 150 K before and 300 K after the reaction. (Assume the cylinder is insulated.)

Which of the following balanced equations describes the reaction?

- (1) $A_2(g) + B_2(g) \longrightarrow 2AB(g)$ (2) $2AB(g) + B_2(g) \longrightarrow 2AB_2(g)$
 (3) $A(g) + B_2(g) \longrightarrow AB_2(g)$ (4) $2AB_2(g) \longrightarrow A_2(g) + 2B_2(g)$

Plan We are shown a depiction of the volume and temperature of a gas mixture before and after a reaction and must deduce the balanced equation. The problem says that P is constant, and the picture shows that, when T doubles, V stays the same. If n were also constant, Charles's law tells us that V should double when T doubles. But, since V does not change, n cannot be constant. From Avogadro's law, the only way to maintain V constant, with P constant and T doubling, is for n to be halved. So, we examine the four balanced equations and count the number of moles on each side to see in which equation n is halved.

Solution In equation (1), n does not change, so doubling T would double V .

In equation (2), n decreases from 3 mol to 2 mol, so doubling T would increase V by one-third.

In equation (3), n decreases from 2 mol to 1 mol. Doubling T would exactly balance the decrease from halving n , so V would stay the same.

In equation (4), n increases, so doubling T would more than double V .

Therefore, equation (3) is correct:

FOLLOW-UP PROBLEMS

5.7A The piston-cylinder below shows the volumes of a gaseous reaction mixture before and after a reaction that takes place at constant pressure and an initial temperature of -73°C .

If the *unbalanced* equation is $CD(g) \longrightarrow C_2(g) + D_2(g)$, what is the final temperature (in $^\circ\text{C}$)?

5.7B The piston-cylinder below shows a gaseous reaction mixture before and after a reaction that takes place at constant pressure.

Which of the following balanced equations describes the reaction?

- (1) $2X_2(g) + Y_2(g) \longrightarrow 2X_2Y(g)$ (2) $2XY_3(g) \longrightarrow X_2(g) + 3Y_2(g)$
 (3) $X_2Y_2(g) \longrightarrow 2X(g) + Y_2(g)$ (4) $2XY(g) \longrightarrow X_2(g) + Y_2(g)$

SOME SIMILAR PROBLEMS 5.19 and 5.67

Summary of Section 5.3

- Four interdependent variables define the physical behavior of an ideal gas: volume (V), pressure (P), temperature (T), and amount (number of moles, n).
- Most simple gases display nearly ideal behavior at ordinary temperatures and pressures.
- Boyle's, Charles's, and Avogadro's laws refer to the linear relationships between the volume of a gas and the pressure, temperature, and amount of the gas, respectively.
- At STP (0°C and 1 atm), 1 mol of an ideal gas occupies 22.4 L.
- The ideal gas law incorporates the individual gas laws into one equation: $PV = nRT$, where R is the universal gas constant.

5.4 REARRANGEMENTS OF THE IDEAL GAS LAW

The ideal gas law can be mathematically rearranged to find gas density, molar mass, the partial pressure of each gas in a mixture, and the amount of gaseous reactant or product in a reaction.

The Density of a Gas

One mole of any gas behaving ideally occupies the same volume at a given temperature and pressure, so differences in gas density ($d = m/V$) depend on differences in molar mass (see Figure 5.10). For example, at STP, 1 mol (32.00 g) of O_2 occupies 22.4 L, the same volume occupied by 1 mol (28.02 g) of N_2 , so

$$d \text{ of } \text{O}_2 = \frac{32.00 \text{ g}}{22.4 \text{ L}} = 1.43 \text{ g/L} \quad \text{and} \quad d \text{ of } \text{N}_2 = \frac{28.02 \text{ g}}{22.4 \text{ L}} = 1.25 \text{ g/L}$$

O_2 is denser because each O_2 molecule has a greater mass (32.00 amu) than each N_2 molecule (28.02 amu).

We can rearrange the ideal gas law to calculate the density of a gas from its molar mass. Recall that the number of moles (n) is the mass of substance (m) divided by its molar mass ($\mathcal{M}$), $n = m/\mathcal{M}$. Substituting for n in the ideal gas law gives

$$PV = \frac{m}{\mathcal{M}} RT$$

Rearranging to isolate m/V gives

$$\frac{m}{V} = d = \frac{P \times \mathcal{M}}{RT} \quad (5.9)$$

Three important ideas are expressed by Equation 5.9:

- *The density of a gas is directly proportional to its molar mass.* The volume of a given amount of a heavier gas equals the volume of the same amount of a lighter gas at the same conditions of temperature and pressure (Avogadro's law), so the density of the heavier gas is higher (as you just saw for O₂ and N₂).
- *The density of a gas is inversely proportional to the temperature.* As the volume of a gas increases with temperature (Charles's law), the same mass occupies more space, so the density of the gas is lower.
- *The density of a gas is directly proportional to the pressure.* As the volume of a gas decreases with increasing pressure (Boyle's law), the same mass occupies less space, so the density of the gas is higher.

We use Equation 5.9 to find the density of a gas at any temperature and pressure near standard conditions.

SAMPLE PROBLEM 5.8 | Calculating Gas Density

Problem To apply a green chemistry approach, a chemical engineer uses waste CO₂ from a manufacturing process, instead of chlorofluorocarbons, as a “blowing agent” in the production of polystyrene. Find the density (in g/L) of CO₂ and the number of molecules per liter (a) at STP (0°C and 1 atm) and (b) at room conditions (20.°C and 1.00 atm).

Plan We must find the density (d) and the number of molecules of CO₂, given two sets of P and T data. We find $\mathcal{M}$, convert T to kelvins, and calculate d with Equation 5.9. Then we convert the mass per liter to molecules per liter with Avogadro's number.

Solution (a) Density and molecules per liter of CO₂ at STP. Summary of gas properties:

$$T = 0^\circ\text{C} + 273.15 = 273 \text{ K} \quad P = 1 \text{ atm} \quad \mathcal{M} \text{ of CO}_2 = 44.01 \text{ g/mol}$$

Calculating density (note the unit canceling here):

$$d = \frac{P \times \mathcal{M}}{RT} = \frac{1.00 \text{ atm} \times 44.01 \text{ g/mol}}{0.0821 \frac{\text{atm} \cdot \text{L}}{\text{mol} \cdot \text{K}} \times 273 \text{ K}} = 1.96 \text{ g/L}$$

Converting from mass/L to molecules/L:

$$\begin{aligned} \text{Molecules CO}_2/\text{L} &= \frac{1.96 \text{ g CO}_2}{1 \text{ L}} \times \frac{1 \text{ mol CO}_2}{44.01 \text{ g CO}_2} \times \frac{6.022 \times 10^{23} \text{ molecules CO}_2}{1 \text{ mol CO}_2} \\ &= 2.68 \times 10^{22} \text{ molecules CO}_2/\text{L} \end{aligned}$$

(b) Density and molecules of CO₂ per liter at room conditions. Summary of gas properties:

$$T = 20.^\circ\text{C} + 273.15 = 293 \text{ K} \quad P = 1.00 \text{ atm} \quad \mathcal{M} \text{ of CO}_2 = 44.01 \text{ g/mol}$$

Calculating density:

$$d = \frac{P \times \mathcal{M}}{RT} = \frac{1.00 \text{ atm} \times 44.01 \text{ g/mol}}{0.0821 \frac{\text{atm} \cdot \text{L}}{\text{mol} \cdot \text{K}} \times 293 \text{ K}} = 1.83 \text{ g/L}$$

Converting from mass/L to molecules/L:

$$\begin{aligned} \text{Molecules CO}_2/\text{L} &= \frac{1.83 \text{ g CO}_2}{1 \text{ L}} \times \frac{1 \text{ mol CO}_2}{44.01 \text{ g CO}_2} \times \frac{6.022 \times 10^{23} \text{ molecules CO}_2}{1 \text{ mol CO}_2} \\ &= 2.50 \times 10^{22} \text{ molecules CO}_2/\text{L} \end{aligned}$$

Check Round off to check the density values; for example, in (a), at STP:

$$\frac{1 \text{ atm} \times 50 \text{ g/mol}}{0.1 \frac{\text{atm} \cdot \text{L}}{\text{mol} \cdot \text{K}} \times 250 \text{ K}} = 2 \text{ g/L} \approx 1.96 \text{ g/L}$$

At the higher temperature in (b), the density should decrease, which can happen only if there are fewer molecules per liter, so the answer is reasonable.

Comment 1. An *alternative approach* for finding the density of most simple gases, but *at STP only*, is to divide the molar mass by the standard molar volume, 22.4 L:

$$d = \frac{\mathcal{M}}{V} = \frac{44.01 \text{ g/mol}}{22.4 \text{ L/mol}} = 1.96 \text{ g/L}$$

Once you know the density at one temperature (0°C), you can find it at any other temperature with the following relationship: $d_1/d_2 = T_2/T_1$ (if the pressure is constant).

2. Note that we have different numbers of significant figures for the pressure values. In (a), “1 atm” is part of the definition of STP, so it is an exact number. In (b), we specified “1.00 atm” to allow three significant figures in the answer.

FOLLOW-UP PROBLEMS

5.8A Compare the density of CO₂ at 0°C and 380. torr with its density at STP.

5.8B Nitrogen oxide (NO₂) is a reddish-brown gas that is a component of smog. Calculate its density at 0.950 atm and 24°C. How does the density of NO₂ compare to that of dry air ($d = 1.13 \text{ g/L}$ at the same conditions)?

SOME SIMILAR PROBLEMS 5.45–5.48

Gas Density and the Human Condition A few applications demonstrate the wide-ranging relevance of gas density:

- *Engineering.* Architectural designers and heating engineers place heating ducts near the floor so that the warmer, and thus less dense, air coming from the ducts will rise and mix with the cooler room air.
- *Safety and air pollution.* In the absence of mixing, a less dense gas will lie above a more dense one. Fire extinguishers that release CO₂ are effective because this gas is heavier than air: it sinks onto the fire and keeps more O₂ from reaching the fuel. The dense gases in smog that blankets urban centers, such as Mexico City, Los Angeles, and Beijing, contribute to respiratory illnesses (see Follow-up Problem 5.8B).
- *Toxic releases.* During World War I, poisonous phosgene gas (COCl₂) was used against ground troops because it was dense enough to sink into their trenches. In 1984, the accidental release of poisonous methylisocyanate gas from a Union Carbide plant in India killed thousands of people as it blanketed nearby neighborhoods. In 1986, CO₂ released naturally from Lake Nyos in Cameroon suffocated thousands of people as it flowed down valleys into villages. Some paleontologists suggest that the release of CO₂ from volcanic lakes may have contributed to the widespread dying off of dinosaurs.
- *Ballooning.* When the gas in a hot-air balloon is heated, its volume increases and the balloon inflates. Further heating causes some of the gas to escape. Thus, the gas density decreases and the balloon rises. In 1783, Jacques Charles (of Charles’s law) made one of the first balloon flights, and, 20 years later, Joseph Gay-Lussac (who studied the pressure-temperature relationship) set a solo altitude record that held for 50 years.

The Molar Mass of a Gas

Through another rearrangement of the ideal gas law, we can determine the molar mass of an unknown gas or a volatile liquid (one that is easily vaporized):

$$n = \frac{m}{\mathcal{M}} = \frac{PV}{RT} \quad \text{so} \quad \mathcal{M} = \frac{mRT}{PV} \quad (5.10)$$

Notice that this equation is just a rearrangement of Equation 5.9.

SAMPLE PROBLEM 5.9 | Finding the Molar Mass of a Volatile Liquid

Problem An organic chemist isolates a colorless liquid from a petroleum sample. She places the liquid in a preweighed flask and puts the flask in boiling water, which vaporizes the liquid and fills the flask with gas. She closes the flask and reweighs it. She obtains the following data:

$$\begin{array}{lll} \text{Volume (V) of flask} = 213 \text{ mL} & T = 100.0^\circ\text{C} & P = 754 \text{ torr} \\ \text{Mass of flask + gas} = 78.416 \text{ g} & \text{Mass of flask} = 77.834 \text{ g} & \end{array}$$

Calculate the molar mass of the liquid.

Plan We are given V , T , P , and mass data and must find the molar mass ($\mathcal{M}$) of the liquid. We convert V to liters, T to kelvins, and P to atmospheres, find the mass of gas by subtracting the mass of the flask from the mass of the flask plus gas, and use Equation 5.10 to calculate $\mathcal{M}$.

Solution Summarizing and converting the gas variables:

$$\begin{array}{ll} V (\text{L}) = 213 \text{ mL} \times \frac{1 \text{ L}}{1000 \text{ mL}} = 0.213 \text{ L} & T (\text{K}) = 100.0^\circ\text{C} + 273.15 = 373.2 \text{ K} \\ P (\text{atm}) = 754 \text{ torr} \times \frac{1 \text{ atm}}{760 \text{ torr}} = 0.992 \text{ atm} & m = 78.416 \text{ g} - 77.834 \text{ g} = 0.582 \text{ g} \end{array}$$

Calculating $\mathcal{M}$:

$$\mathcal{M} = \frac{mRT}{PV} = \frac{0.582 \text{ g} \times 0.0821 \frac{\text{atm}\cdot\text{L}}{\text{mol}\cdot\text{K}} \times 373.2 \text{ K}}{0.992 \text{ atm} \times 0.213 \text{ L}} = 84.4 \text{ g/mol}$$

Check Rounding to check the arithmetic, we have

$$\frac{0.6 \text{ g} \times 0.08 \frac{\text{atm}\cdot\text{L}}{\text{mol}\cdot\text{K}} \times 375 \text{ K}}{1 \text{ atm} \times 0.2 \text{ L}} = 90 \text{ g/mol} \quad (\text{which is close to } 84.4 \text{ g/mol})$$

FOLLOW-UP PROBLEMS

5.9A An empty 149-mL flask weighs 68.322 g before a sample of volatile liquid is added. The flask is then placed in a hot (95.0°C) water bath; the barometric pressure is 740. torr. The liquid vaporizes and the gas fills the flask. After cooling, flask and condensed liquid together weigh 68.697 g. What is the molar mass of the liquid?

5.9B An empty glass bulb has a volume of 350. mL and a mass of 82.561 g. When filled with an unknown gas at 733 mmHg and 22°C , the bulb has a mass of 82.786 g. Is the gas argon (Ar), methane (CH_4), or nitrogen monoxide (NO)?

SOME SIMILAR PROBLEMS 5.49 and 5.50

The Partial Pressure of Each Gas in a Mixture of Gases

The ideal gas law holds for virtually any gas at ordinary conditions, whether it is a pure gas or a mixture of gases such as air, because

- Gases mix homogeneously (form a solution) in any proportions.
- Each gas in a mixture behaves as if it were the only gas present (assuming no chemical interactions).

Dalton's Law of Partial Pressures The second point above was discovered by John Dalton during his lifelong study of humidity. He observed that, when water vapor is added to dry air, the total air pressure increases by the pressure of the water vapor:

$$P_{\text{humid air}} = P_{\text{dry air}} + P_{\text{added water vapor}}$$

He concluded that each gas in the mixture exerts a **partial pressure** equal to the pressure it would exert if it were *by itself*. His discovery is stated as follows:

- **Dalton's law of partial pressures:** *in a mixture of unreacting gases, the total pressure is the sum of the partial pressures of the individual gases, or*

$$P_{\text{total}} = P_1 + P_2 + P_3 + \cdots \quad (5.11)$$

As an example, suppose we have a tank of fixed volume that contains nitrogen gas at a certain pressure, and we introduce a sample of hydrogen gas into the tank. Each gas behaves independently, so we can write an ideal gas law expression for each:

$$P_{\text{N}_2} = \frac{n_{\text{N}_2}RT}{V} \quad \text{and} \quad P_{\text{H}_2} = \frac{n_{\text{H}_2}RT}{V}$$

Because each gas occupies the same total volume and is at the same temperature, the pressure of each gas depends only on its amount, n . Thus, the total pressure is

$$P_{\text{total}} = P_{\text{N}_2} + P_{\text{H}_2} = \frac{n_{\text{N}_2}RT}{V} + \frac{n_{\text{H}_2}RT}{V} = \frac{(n_{\text{N}_2} + n_{\text{H}_2})RT}{V} = \frac{n_{\text{total}}RT}{V}$$

where $n_{\text{total}} = n_{\text{N}_2} + n_{\text{H}_2}$.

Each component in a mixture contributes a fraction of the total number of moles in the mixture; this portion is the **mole fraction** (X) of that component. Multiplying X by 100 gives the mole percent. The sum of the mole fractions of all components must be 1, and the sum of the mole percents must be 100%. For N_2 in our mixture, the mole fraction is

$$X_{\text{N}_2} = \frac{\text{mol of N}_2}{\text{total amount (mol)}} = \frac{n_{\text{N}_2}}{n_{\text{N}_2} + n_{\text{H}_2}}$$

If the total pressure is due to the total number of moles, the partial pressure of gas A is the total pressure multiplied by the mole fraction of A, X_A :

$$P_A = X_A \times P_{\text{total}} \quad (5.12)$$

For example, if $\frac{1}{4}$ (0.25) of a gas mixture is gas A, then gas A contributes $\frac{1}{4}$ of the total pressure.

Equation 5.12 is a very useful result. To see that it is valid for the mixture of N_2 and H_2 , we recall that $X_{\text{N}_2} + X_{\text{H}_2} = 1$; then we obtain

$$P_{\text{total}} = P_{\text{N}_2} + P_{\text{H}_2} = (X_{\text{N}_2} \times P_{\text{total}}) + (X_{\text{H}_2} \times P_{\text{total}}) = (X_{\text{N}_2} + X_{\text{H}_2})P_{\text{total}} = 1 \times P_{\text{total}}$$

Road Map

SAMPLE PROBLEM 5.10 | Applying Dalton's Law of Partial Pressures

Problem To prevent air from interacting with highly reactive chemicals, noble gases are placed over the chemicals to act as inert “blanketing” gases. A chemical engineer places a mixture of noble gases consisting of 5.50 g of He, 15.0 g of Ne, and 35.0 g of Kr in a piston-cylinder assembly at 25°C and 0.885 atm. Calculate the partial pressure of each gas.

Plan We are given the mass of each gas and the total pressure; we convert mass of each gas to amount in moles and add the three amounts to find n_{total} . Then we divide the amount of each gas by n_{total} to obtain the mole fraction of the gas and multiply by the total pressure to obtain partial pressure (Equation 5.12; see the road map).

Solution Converting from mass (g) to amount (mol) for He:

$$\text{Amount (mol) of He} = 5.50 \text{ g He} \times \frac{1 \text{ mol He}}{4.003 \text{ g He}} = 1.37 \text{ mol He}$$

Similarly, there are 0.743 mol Ne and 0.418 mol Kr.

Finding the total amount of gas (mol):

$$n_{\text{total}} = n_{\text{He}} + n_{\text{Ne}} + n_{\text{Kr}} = 1.37 \text{ mol He} + 0.743 \text{ mol Ne} + 0.418 \text{ mol Kr} = 2.53 \text{ mol}$$

Calculating the partial pressure (atm) of He, Ne, and Kr:

$$P_{\text{He}} = X_{\text{He}} \times P_{\text{total}} = \frac{1.37 \text{ mol He}}{2.53 \text{ mol gas}} \times 0.885 \text{ atm} = 0.479 \text{ atm}$$

$$P_{\text{Ne}} = X_{\text{Ne}} \times P_{\text{total}} = \frac{0.743 \text{ mol Ne}}{2.53 \text{ mol gas}} \times 0.885 \text{ atm} = 0.260 \text{ atm}$$

$$P_{\text{Kr}} = X_{\text{Kr}} \times P_{\text{total}} = \frac{0.418 \text{ mol Kr}}{2.53 \text{ mol gas}} \times 0.885 \text{ atm} = 0.146 \text{ atm}$$

Check The sum of the partial pressures must equal the total pressure: $0.479 \text{ atm} + 0.260 \text{ atm} + 0.146 \text{ atm} = 0.885 \text{ atm}$.

FOLLOW-UP PROBLEMS

5.10A In a study of O_2 uptake by muscle tissue at high altitude, a physiologist prepares an atmosphere consisting of 79 mole % N_2 , 17 mole % $^{16}\text{O}_2$, and 4.0 mole % $^{18}\text{O}_2$. (The isotope ^{18}O will be measured to determine O_2 uptake.) The total pressure is 0.75 atm to simulate high altitude. Calculate the mole fraction and partial pressure of $^{18}\text{O}_2$ in the mixture.

5.10B Trimix is a breathing mixture of He, O_2 , and N_2 used by deep-sea scuba divers; He reduces the chances of N_2 narcosis and O_2 toxicity. A tank of Trimix has a total pressure of 204 atm and a partial pressure of He of 143 atm. What is the mole percent of He in the mixture?

SOME SIMILAR PROBLEMS 5.51 and 5.52

Collecting a Gas over Water Several reactions produce a gas that might be collected in an experimental setup similar to that shown in Figure 5.13. As one example, the decomposition reaction of potassium chlorate produces oxygen gas:

The gaseous product is collected through the displacement of water; as the water-insoluble gas bubbles through the water, some water vaporizes into the bubbles, and the mixture of product gas and water vapor is collected into an inverted container.

Figure 5.13 Collecting a water-insoluble gaseous product and determining its pressure.

Table 5.2 | Vapor Pressure of Water ($P_{\text{H}_2\text{O}}$) at Different T

$T(^{\circ}\text{C})$	$P_{\text{H}_2\text{O}}(\text{torr})$	$T(^{\circ}\text{C})$	$P_{\text{H}_2\text{O}}(\text{torr})$	$T(^{\circ}\text{C})$	$P_{\text{H}_2\text{O}}(\text{torr})$	$T(^{\circ}\text{C})$	$P_{\text{H}_2\text{O}}(\text{torr})$
0	4.58	20	17.55	40	55.39	75	289.49
5	6.54	22	19.84	45	71.97	80	355.63
10	9.21	24	22.40	50	92.65	85	434.04
12	10.66	26	25.23	55	118.22	90	526.41
14	11.99	28	28.38	60	149.61	95	634.61
16	13.64	30	31.86	65	187.83	100	760.0
18	15.49	35	42.22	70	234.03		

The water vapor that mixes with the gas contributes a pressure known as the vapor pressure, which depends only on the water temperature (Table 5.2). Thus, according to Dalton's law, the pressure of the collected gas/water mixture is the sum of the pressure of the gas and the vapor pressure:

$$P_{\text{total}} = P_{\text{gas}} + P_{\text{H}_2\text{O}}$$

To determine the amount of gas formed, we look up the vapor pressure at the temperature of the experiment in Table 5.2 and subtract it from the total gas pressure to get the partial pressure of the gaseous product. With V and T known, we can calculate the amount of product.

SAMPLE PROBLEM 5.11 | Calculating the Amount of Gas Collected over Water

Problem Acetylene (C_2H_2), an important fuel in welding, is produced in the laboratory when calcium carbide (CaC_2) reacts with water:

For a sample of acetylene collected over water, total gas pressure (adjusted to barometric pressure) is 738 torr and the volume is 523 mL. At the temperature of the gas (23°C), the vapor pressure of water is 21 torr. How many grams of acetylene are collected?

Plan In order to find the mass of C_2H_2 , we first need to find the number of moles of C_2H_2 , $n_{\text{C}_2\text{H}_2}$, which we can obtain from the ideal gas law by calculating $P_{\text{C}_2\text{H}_2}$. The barometer reading gives us P_{total} , which is the sum of $P_{\text{C}_2\text{H}_2}$ and $P_{\text{H}_2\text{O}}$, and we are given $P_{\text{H}_2\text{O}}$, so we subtract to find $P_{\text{C}_2\text{H}_2}$. We are also given V and T , so we convert to consistent units and find $n_{\text{C}_2\text{H}_2}$ from the ideal gas law. Then we convert moles to grams using the molar mass from the formula for acetylene, as shown in the road map.

Solution Summarizing and converting the gas variables:

$$P_{\text{C}_2\text{H}_2}(\text{torr}) = P_{\text{total}} - P_{\text{H}_2\text{O}} = 738 \text{ torr} - 21 \text{ torr} = 717 \text{ torr}$$

$$P_{\text{C}_2\text{H}_2}(\text{atm}) = 717 \text{ torr} \times \frac{1 \text{ atm}}{760 \text{ torr}} = 0.943 \text{ atm}$$

$$V(\text{L}) = 523 \text{ mL} \times \frac{1 \text{ L}}{1000 \text{ mL}} = 0.523 \text{ L}$$

$$T(\text{K}) = 23^{\circ}\text{C} + 273.15 = 296 \text{ K}$$

$$n_{\text{C}_2\text{H}_2} = \text{unknown}$$

Solving for $n_{\text{C}_2\text{H}_2}$:

$$n_{\text{C}_2\text{H}_2} = \frac{PV}{RT} = \frac{0.943 \text{ atm} \times 0.523 \text{ L}}{0.0821 \frac{\text{atm} \cdot \text{L}}{\text{mol} \cdot \text{K}} \times 296 \text{ K}} = 0.0203 \text{ mol}$$

Converting $n_{\text{C}_2\text{H}_2}$ to mass (g):

$$\begin{aligned} \text{Mass (g) of } \text{C}_2\text{H}_2 &= 0.0203 \text{ mol } \text{C}_2\text{H}_2 \times \frac{26.04 \text{ g } \text{C}_2\text{H}_2}{1 \text{ mol } \text{C}_2\text{H}_2} \\ &= 0.529 \text{ g } \text{C}_2\text{H}_2 \end{aligned}$$

Check Rounding to one significant figure, a quick arithmetic check for n gives

$$n \approx \frac{1 \text{ atm} \times 0.5 \text{ L}}{0.08 \frac{\text{atm} \cdot \text{L}}{\text{mol} \cdot \text{K}} \times 300 \text{ K}} = 0.02 \text{ mol} \approx 0.0203 \text{ mol}$$

Road Map

Comment The C_2^{2-} ion (called the *carbide*, or *acetylide, ion*) is an interesting anion. It is simply $\text{C}\equiv\text{C}^{2-}$, which acts as a base in water, removing an H^+ ion from two H_2O molecules to form acetylene, $\text{H}-\text{C}\equiv\text{C}-\text{H}$.

FOLLOW-UP PROBLEMS

5.11A A small piece of zinc reacts with dilute HCl to form H_2 , which is collected over water at 16°C into a large flask. The total pressure is adjusted to barometric pressure (752 torr), and the volume is 1495 mL. Use Table 5.2 to calculate the partial pressure and mass of H_2 .

5.11B Heating a sample of KClO_3 produces O_2 , which is collected over water at 20°C . The total pressure, after adjusting to barometric pressure, is 748 torr, and the gas volume is 307 mL. Use Table 5.2 to calculate the partial pressure and mass of O_2 .

SOME SIMILAR PROBLEMS 5.57 and 5.58

The Ideal Gas Law and Reaction Stoichiometry

As you saw in Chapters 3 and 4, and in the preceding discussion of collecting a gas over water, many reactions involve gases as reactants or products. From the balanced equation for such a reaction, you can calculate the amounts (mol) of reactants and products and convert these quantities into masses or numbers of molecules. Figure 5.14 shows how to use the ideal gas law to convert between gas variables (P , V , and T) and amounts (mol) of gaseous reactants and products. In effect, you combine a gas law problem with a stoichiometry problem, as you'll see in Sample Problems 5.12 and 5.13.

Figure 5.14 The relationships among the amount (mol, n) of gaseous reactant (or product) and the gas pressure (P), volume (V), and temperature (T).

Student Hot Spot

Student data indicate that you may struggle with problems that combine stoichiometry and the ideal gas law. Access the eBook to view an additional Learning Resource video on this topic.

SAMPLE PROBLEM 5.12

Using Gas Variables to Find Amounts of Reactants or Products I

Problem Solid lithium hydroxide is used to “scrub” CO_2 from the air in spacecraft and submarines; it reacts with the CO_2 to produce lithium carbonate and water. What volume of CO_2 at 23°C and 716 torr can be removed by reaction with 395 g of lithium hydroxide?

Plan This is a stoichiometry *and* a gas law problem. To find V_{CO_2} , we first need n_{CO_2} . We write and balance the equation. Next, we convert the given mass (395 g) of lithium hydroxide, LiOH , to amount (mol) and use the molar ratio to find amount (mol) of CO_2 that reacts (stoichiometry portion). Then, we use the ideal gas law to convert moles of CO_2 to liters (gas law portion). A road map is shown, but you are familiar with all the steps.

Solution Writing the balanced equation:

Calculating n_{CO_2} :

$$n_{\text{CO}_2} = 395 \text{ g LiOH} \times \frac{1 \text{ mol LiOH}}{23.95 \text{ g LiOH}} \times \frac{1 \text{ mol CO}_2}{2 \text{ mol LiOH}} = 8.25 \text{ mol CO}_2$$

Summarizing and converting other gas variables:

$$V = \text{unknown} \quad P (\text{atm}) = 716 \text{ torr} \times \frac{1 \text{ atm}}{760 \text{ torr}} = 0.942 \text{ atm}$$

$$T (\text{K}) = 23^\circ\text{C} + 273.15 = 296 \text{ K}$$

Solving for V_{CO_2} :

$$V = \frac{nRT}{P} = \frac{8.25 \text{ mol} \times 0.0821 \frac{\text{atm}\cdot\text{L}}{\text{mol}\cdot\text{K}} \times 296 \text{ K}}{0.942 \text{ atm}} = 213 \text{ L}$$

Road Map

Check One way to check the answer is to compare it with the molar volume of an ideal gas at STP (22.4 L at 273.15 K and 1 atm). One mole of CO_2 at STP occupies about 22 L, so about 8 mol occupies $8 \times 22 = 176$ L. T is a little higher than 273 K, and P is slightly lower than 1 atm, so V should be somewhat larger than 176 L.

Comment The main point here is that the stoichiometry provides one gas variable (n), two more are given (P and T), and the ideal gas law is used to find the fourth (V).

FOLLOW-UP PROBLEMS

5.12A Solid silicon dioxide is reduced with carbon to produce silicon and carbon monoxide. What mass of silicon dioxide must react with excess carbon to produce 44.8 L of CO(g) at 0.975 atm and 25°C ?

5.12B Engineers use copper in absorbent beds to react with and remove oxygen impurities from ethylene that is used to make polyethylene. The beds are regenerated when hot H_2 reduces the copper(II) oxide, forming the pure metal and H_2O . On a laboratory scale, what volume of H_2 at 765 torr and 225°C is needed to reduce 35.5 g of copper(II) oxide?

SOME SIMILAR PROBLEMS 5.53 and 5.54

SAMPLE PROBLEM 5.13

Using Gas Variables to Find Amounts of Reactants or Products II

Chlorine gas reacting with potassium.

Source: Stephen Frisch/McGraw Hill

Problem The alkali metals (Group 1) react with the halogens (Group 17) to form ionic metal halides. What mass of potassium chloride forms when 5.25 L of chlorine gas at 0.950 atm and 293 K reacts with 17.0 g of potassium (*see photo*)?

Plan The amounts of two reactants are given, so this is a limiting-reactant problem. The only difference between this and previous limiting-reactant problems (see Sample Problem 3.16) is that here we use the ideal gas law to find the amount (n) of gaseous reactant from the known V , P , and T . We first write the balanced equation and then use it to find the limiting reactant and the amount and mass of product.

Solution Writing the balanced equation:

Summarizing the gas variables for $\text{Cl}_2\text{(g)}$:

$$\begin{array}{ll} P = 0.950 \text{ atm} & V = 5.25 \text{ L} \\ T = 293 \text{ K} & n = \text{unknown} \end{array}$$

Solving for n_{Cl_2} :

$$n_{\text{Cl}_2} = \frac{PV}{RT} = \frac{0.950 \text{ atm} \times 5.25 \text{ L}}{0.0821 \frac{\text{atm} \cdot \text{L}}{\text{mol} \cdot \text{K}} \times 293 \text{ K}} = 0.207 \text{ mol}$$

Converting from mass (g) of potassium (K) to amount (mol):

$$\text{Amount (mol) of K} = 17.0 \text{ g K} \times \frac{1 \text{ mol K}}{39.10 \text{ g K}} = 0.435 \text{ mol K}$$

Determining the limiting reactant: if Cl_2 is limiting,

$$\text{Amount (mol) of KCl} = 0.207 \text{ mol Cl}_2 \times \frac{2 \text{ mol KCl}}{1 \text{ mol Cl}_2} = 0.414 \text{ mol KCl}$$

If K is limiting,

$$\text{Amount (mol) of KCl} = 0.435 \text{ mol K} \times \frac{2 \text{ mol KCl}}{2 \text{ mol K}} = 0.435 \text{ mol KCl}$$

Cl_2 is the limiting reactant because it forms less KCl. Converting from amount (mol) of KCl to mass (g):

$$\text{Mass (g) of KCl} = 0.414 \text{ mol KCl} \times \frac{74.55 \text{ g KCl}}{1 \text{ mol KCl}} = 30.9 \text{ g KCl}$$

Check The gas law calculation seems correct. At STP, 22 L of Cl_2 gas contains about 1 mol, so a 5-L volume will contain a bit less than 0.25 mol of Cl_2 . Moreover, since P (in numerator) is slightly lower than STP, and T (in denominator) is slightly higher than STP, these should lower the calculated n further below the ideal value. The mass of KCl seems correct: less than 0.5 mol of KCl gives $<0.5 \text{ mol} \times M$ ($\sim 75 \text{ g/mol}$), and $30.9 \text{ g} < 0.5 \text{ mol} \times 75 \text{ g/mol}$.

FOLLOW-UP PROBLEMS

5.13A Ammonia and hydrogen chloride gases react to form solid ammonium chloride. A 10.0-L reaction flask contains ammonia at 0.452 atm and 22°C, and 155 mL of hydrogen chloride gas at 7.50 atm and 271 K is introduced. After the reaction occurs and the temperature returns to 22°C, what is the pressure inside the flask? (Neglect the volume of the solid product.)

5.13B What volume of gaseous iodine pentafluoride, measured at 105°C and 0.935 atm, can be prepared by the reaction of 4.16 g of solid iodine with 2.48 L of gaseous fluorine at 18°C and 0.974 atm?

SOME SIMILAR PROBLEMS 5.55 and 5.56

› Summary of Section 5.4

- › Gas density is inversely related to temperature and directly related to pressure: higher T and lower P causes lower d , and vice versa. At the same P and T , gases with larger values of $\mathcal{M}$ have higher values of d .
- › In a mixture of gases, each component contributes its partial pressure to the total pressure (Dalton's law of partial pressures). The mole fraction of each component is the ratio of its partial pressure to the total pressure.
- › When a gaseous reaction product is collected by bubbling it through water, the total pressure is the sum of the gas pressure and the vapor pressure of water at the given temperature.
- › By converting the variables P , V , and T for a gaseous reactant (or product) to amount (n , mol), we can solve stoichiometry problems for gaseous reactions.

5.5

THE KINETIC-MOLECULAR THEORY: A MODEL FOR GAS BEHAVIOR

The **kinetic-molecular theory** is the model that accounts for macroscopic gas behavior at the level of individual particles (atoms or molecules). Developed in the 19th century, the theory was able to explain the gas laws that some scientists of the 18th century had arrived at through experiments. The theory draws quantitative conclusions based on a few postulates (assumptions), but our discussion will be largely qualitative.

How the Kinetic-Molecular Theory Explains the Gas Laws

Let's state the postulates of the kinetic-molecular theory and then draw conclusions that explain the gas laws and related phenomena.

Postulates of the Kinetic-Molecular Theory The theory is based on four postulates:

Postulate 1. *Particle volume.* A gas consists of a large collection of individual particles with empty space between them. The volume of each particle is so small compared with the volume of the whole sample that it is assumed to be zero; each particle is essentially a point of mass.

Postulate 2. *Particle motion.* The particles are in constant, random, straight-line motion, except when they collide with the container walls or with each other.

Postulate 3. *Particle collisions.* The collisions are *elastic*, which means that, like minute billiard balls on a frictionless billiards table, the colliding particles exchange energy but do not lose any energy through friction. Thus, *their total kinetic energy (E_k) is constant*. Between collisions, the particles do not exert attractive or repulsive forces on each other.

Postulate 4. *Particle energy.* The average kinetic energy of the gas particles, $\overline{E_k}$, is proportional to absolute temperature:

$$\overline{E_k} \propto T$$

Thus, at a given temperature, all gases have the same average kinetic energy.

Figure 5.15 Distribution of molecular speeds for N_2 at three temperatures.

Figure 5.15 depicts the distribution of molecular speeds for N_2 gas at three temperatures. Three observations can be made from the graph:

- The curves flatten and spread at higher temperatures;
- Some particles are moving faster than the most probable speed and others are moving slower;
- The most probable speed (the peak of each curve) increases as the temperature increases. This increase in speed is due to the fact that average kinetic energy increases as temperature increases. The particles move faster when they have more kinetic energy.

**Figure 5.16** Pressure arises from countless collisions between gas particles and walls.

A Molecular View of the Gas Laws Let's visualize gas particles in a container to see how the theory explains the macroscopic behavior of gases.

1. *Origin of pressure.* Pressure is a measure of the force a gas exerts on a surface. How do individual gas particles create this force? From postulates 1 and 2, each gas particle (point of mass) colliding with the container walls (and bottom of piston) exerts a force (Figure 5.16). Countless collisions over the inner surface of the container result in a pressure. The greater the number of particles, the more frequently they collide with the container and, so, the greater the pressure.

2. *Boyle's law* ($V \propto 1/P$). A change in gas pressure in one direction causes a change in gas volume in the other. According to postulate 1 of the kinetic-molecular theory, the particles in a gas are points of mass with empty space between them. Therefore, under an external force, the gas particles can be pushed closer together. Figure 5.17 shows what happens to gas particles when external pressure compresses the gas volume:

- Before any change in pressure, the pressure exerted by the gas (P_{gas}) equals the pressure exerted on the gas (P_{ext}), and there is some average distance (d_1) between the particles and the container walls.
- As P_{ext} increases at constant temperature, the average distance (d_2) between the particles and the walls decreases (that is, $d_2 < d_1$), and so the sample volume **decreases**.

Figure 5.17 A molecular view of Boyle's law.

Figure 5.18 A molecular view of Charles's law.

- Collisions of the particles with the walls become more frequent over the shorter average distance, which causes P_{gas} to **increase** until it again equals P_{ext} .

Liquids and solids cannot be compressed because there is little, if any, free space between their particles.

3. *Charles's law* ($V \propto T$). A change in temperature causes a corresponding change in volume. Figure 5.18 shows the effect of higher temperature on gas particles that results in increased gas volume:

- At some starting temperature, T_1 , the external (atmospheric) pressure (P_{atm}) equals the pressure of the gas (P_{gas}).
- When the gas is heated and the **temperature increases** to T_2 , the most probable molecular speed and the average kinetic energy increase, as stated in postulate 4 of the kinetic-molecular theory.
- Thus, the particles hit the walls more frequently *and* more energetically. This change temporarily increases P_{gas} . As a result, the piston moves up, which **increases the volume** and lowers the number of collisions with the walls until P_{atm} and P_{gas} are again equal.

4. *Avogadro's law* ($V \propto n$). Gas volume increases as the number of moles of gas increases. Figure 5.19 illustrates this process:

- At the start, there is an initial amount of gas, n_1 , and an initial number of particles that collide with the walls of the container so that P_{gas} equals P_{atm} .
- When more gas is added from the attached tank, the **amount increases** to n_2 . Thus, more particles hit the container walls more frequently (postulate 2 of the kinetic-molecular theory), which temporarily increases P_{gas} .
- As a result, the piston moves up, which **increases the volume** and lowers the number of collisions with the walls until P_{atm} and P_{gas} are equal again.

Figure 5.19 A molecular view of Avogadro's law.

Figure 5.20 A molecular view of Dalton's law.

5. *Dalton's law of partial pressures* ($P_{\text{total}} = P_1 + P_2 + P_3 + \dots$). The pressure of a gas mixture is the sum of the pressures of the individual gases. Figure 5.20 helps us understand why each gas contributes to the total pressure in proportion to its number of particles:

- At a given temperature, a given amount of gas B exerts a pressure that is dependent only on the number of particles of the gas.
- When a given amount of gas A is added to gas B, there is an increase in the total amount of particles, in proportion to the particles of A added.
- This increase causes a corresponding increase in the total number of collisions with the walls per second (postulate 2 of the kinetic-molecular theory), which causes a corresponding increase in the total gas mixture (P_{total}).
- Each gas exerts a fraction of P_{total} in proportion to its fraction of the total number of particles (or, its fraction of the total number of moles, that is, the mole fraction).

The Central Importance of Kinetic Energy As we know, Avogadro's law says that, at any given T and P , the volume of a gas depends only on the number of moles—that is, number of particles—in the sample. Notice that the law doesn't mention the chemical nature of the gas, so equal numbers of particles of any two gases—say, O_2 and H_2 —should occupy the same volume. But why don't the heavier O_2 molecules, which strike the container walls with more force than the lighter H_2 molecules, exert more pressure and thus take up more volume? Kinetic energy is the key to answering this question:

- Postulate 4 of the kinetic-molecular theory states that all gases have the same average kinetic energy at a particular temperature.
- We can mathematically express kinetic energy as

$$E_k = \frac{1}{2} \text{mass} \times \text{speed}^2$$

This equation shows that, for a given E_k , an object's mass and speed are inversely related: a heavy object moving slower has the same kinetic energy as a light object moving faster.

Figure 5.21 illustrates this fact; several gases at the same temperature have the same average kinetic energy. We see that the most probable molecular speed (*top of the curve*) increases as molar mass (*number in parentheses*) decreases: *lighter particles move faster, on average, than heavier particles*.

Their higher most probable speed means that H_2 molecules collide with the walls of a container *more often* than O_2 molecules do, but their lower mass means that each collision has *less force*. Therefore, because the molecules of any gas hit the walls with the same kinetic energy, *at a given T , equimolar samples of any gases exert the same pressure (force per unit area) and, thus, occupy the same volume.*

Figure 5.21 The relationship between molar mass and molecular speed.

The Meaning of Temperature Earlier we saw that kinetic energy is proportional to absolute temperature; that is, $\overline{E_k} \propto T$, which can also be expressed as $\overline{E_k} = c \times T$. The definitions of velocity, momentum, force, and pressure let us express this relationship as the following equation (although we won't derive it):

$$\overline{E_k} = \frac{3}{2} \left(\frac{R}{N_A} \right) T$$

where R is the gas constant and N_A is the symbol for Avogadro's number. This equation makes the essential point that *temperature is a measure of the average kinetic energy of the particles*: as T goes up, $\overline{E_k}$ increases, and, as T goes down, $\overline{E_k}$ decreases. Temperature is an intensive property (see Section 1.5), so it is not related to the *total* energy of motion of the particles, which depends on the size of the sample, but to the *average* energy.

Thus, for example, in the macroscopic world, we heat a beaker of water over a flame and see the mercury rise inside a thermometer in the beaker. We see this because, in the molecular world, kinetic energy transfers, in turn, from higher energy gas particles in the flame to lower energy particles in the beaker glass, the water molecules, the particles in the thermometer glass, and the atoms of mercury.

Root-Mean-Square Speed Finally, let's derive an expression for the speed of a gas particle that has the average kinetic energy of the particles in a sample. From the general expression for kinetic energy of an object,

$$E_k = \frac{1}{2} \text{mass} \times \text{speed}^2$$

the average kinetic energy of each particle in a large population is

$$\overline{E_k} = \frac{1}{2} m \overline{u^2}$$

where m is the particle's mass (atomic or molecular) and $\overline{u^2}$ is the average of the squares of the molecular speeds. Setting this expression for average kinetic energy equal to the earlier one gives

$$\frac{1}{2} m \overline{u^2} = \frac{3}{2} \left(\frac{R}{N_A} \right) T$$

Multiplying through by Avogadro's number, N_A , gives the average kinetic energy for a mole of gas particles:

$$\frac{1}{2} N_A m \overline{u^2} = \frac{3}{2} RT$$

Avogadro's number times the molecular mass, $N_A \times m$, is the molar mass, $\mathcal{M}$, and, solving for $\overline{u^2}$, we have

$$\overline{u^2} = \frac{3RT}{\mathcal{M}}$$

The square root of $\overline{u^2}$ is the root-mean-square speed, or **rms speed** (u_{rms}): *a particle moving at this speed has the average kinetic energy*.* That is, taking the square root of both sides of the previous equation gives

$$u_{\text{rms}} = \sqrt{\frac{3RT}{\mathcal{M}}} \quad (5.13)$$

*The rms speed, u_{rms} , is proportional to, but slightly higher than, the most probable speed; for an ideal gas, $u_{\text{rms}} = 1.09 \times \text{average speed}$.

where R is the gas constant, T is the absolute temperature, and $\mathcal{M}$ is the molar mass. We want u in m/s, so we use the value $8.314 \text{ J/mol}\cdot\text{K}$ for R since the joule unit (J) can be expressed as $\text{kg}\cdot\text{m}^2/\text{s}^2$; we also must express $\mathcal{M}$ in kg/mol .

Let's use this equation to compare the root-mean-square speed of an O_2 molecule at 20°C to its root-mean-square speed at 120°C and to the root-mean-square speed of a lighter H_2 molecule at 20°C :

O_2 molecule at 20°C $\mathcal{M} = 3.200 \times 10^{-2} \text{ kg/mol}$	O_2 molecule at 120°C $\mathcal{M} = 3.200 \times 10^{-2} \text{ kg/mol}$	H_2 molecule at 20°C $\mathcal{M} = 2.016 \times 10^{-3} \text{ kg/mol}$
$\mu_{\text{rms}} = \sqrt{\frac{3RT}{\mathcal{M}}} = \sqrt{\frac{3(8.314 \text{ J/mol}\cdot\text{K})(293 \text{ K})}{3.200 \times 10^{-2} \text{ kg/mol}}}$ $= \sqrt{\frac{3(8.314 \text{ kg}\cdot\text{m}^2/\text{s}^2/\text{mol}\cdot\text{K})(293 \text{ K})}{3.200 \times 10^{-2} \text{ kg/mol}}}$ $= 478 \text{ m/s (1070 mi/h)}$	$\mu_{\text{rms}} = \sqrt{\frac{3RT}{\mathcal{M}}} = \sqrt{\frac{3(8.314 \text{ J/mol}\cdot\text{K})(393 \text{ K})}{3.200 \times 10^{-2} \text{ kg/mol}}}$ $= \sqrt{\frac{3(8.314 \text{ kg}\cdot\text{m}^2/\text{s}^2/\text{mol}\cdot\text{K})(393 \text{ K})}{3.200 \times 10^{-2} \text{ kg/mol}}}$ $= 553 \text{ m/s (1240 mi/h)}$	$\mu_{\text{rms}} = \sqrt{\frac{3RT}{\mathcal{M}}} = \sqrt{\frac{3(8.314 \text{ J/mol}\cdot\text{K})(293 \text{ K})}{2.016 \times 10^{-3} \text{ kg/mol}}}$ $= \sqrt{\frac{3(8.314 \text{ kg}\cdot\text{m}^2/\text{s}^2/\text{mol}\cdot\text{K})(293 \text{ K})}{2.016 \times 10^{-3} \text{ kg/mol}}}$ $= 1900 \text{ m/s (4250 mi/h)}$

These calculations confirm what we stated earlier:

- the velocity of a gas particle increases with increasing temperature, and
- the velocity of a gas particle decreases with increasing molar mass.

Effusion and Diffusion

The movement of a gas into a vacuum and the movement of gases through one another are phenomena with some vital applications.

The Process of Effusion One of the early triumphs of the kinetic-molecular theory was an explanation of **effusion**, the process by which a gas escapes through a tiny hole in its container into an evacuated space. In 1846, Thomas Graham studied the effusion rate of a gas, the number of molecules escaping per unit time, and found that it was inversely proportional to the square root of the gas density. But, density is directly related to molar mass, so the relationship is stated as follows:

- **Graham's law of effusion:** *the rate of effusion of a gas is inversely proportional to the square root of its molar mass, or*

$$\text{Rate of effusion} \propto \frac{1}{\sqrt{\mathcal{M}}}$$

From Equation 5.13, we see that, at a given temperature and pressure, a gas with a lower molar mass has a greater rms speed than a gas with a higher molar mass; *since the rms speed of its atoms is higher, more atoms of the lighter gas reach the hole and escape per unit time* (Figure 5.22). At constant T , the ratio of the effusion rates of two gases, A and B, is

$$\frac{\text{Rate}_A}{\text{Rate}_B} = \frac{u_{\text{rms of A}}}{u_{\text{rms of B}}} = \frac{\sqrt{3RT/\mathcal{M}_A}}{\sqrt{3RT/\mathcal{M}_B}} = \frac{\sqrt{\mathcal{M}_B}}{\sqrt{\mathcal{M}_A}} = \sqrt{\frac{\mathcal{M}_B}{\mathcal{M}_A}} \quad (5.14)$$

For example, earlier we compared the root-mean-square speed of O_2 at 293 K (478 m/s) to that of a H_2 molecule at the same temperature (1900 m/s); the root-mean-square speed of the H_2 molecule is four times faster:

$$\frac{\text{Rate}_{\text{H}_2}}{\text{Rate}_{\text{O}_2}} = \frac{u_{\text{rms of H}_2}}{u_{\text{rms of O}_2}} = \frac{1900 \text{ m/s}}{478 \text{ m/s}} = \frac{\sqrt{\mathcal{M}_{\text{O}_2}}}{\sqrt{\mathcal{M}_{\text{H}_2}}} = \frac{\sqrt{32.00 \text{ g/mol}}}{\sqrt{2.016 \text{ g/mol}}} = 4$$

Graham's law can be used to determine the molar mass of an unknown gas. By comparing the effusion rate of gas X with that of a known gas, such as He, we can solve for the molar mass of X:

$$\frac{\text{Rate}_X}{\text{Rate}_{\text{He}}} = \sqrt{\frac{\mathcal{M}_{\text{He}}}{\mathcal{M}_X}}$$

Squaring both sides and solving for the molar mass of X gives

$$\mathcal{M}_X = \mathcal{M}_{\text{He}} \times \left(\frac{\text{rate}_{\text{He}}}{\text{rate}_X} \right)^2$$

Figure 5.22 Effusion. Lighter (black) particles effuse faster than heavier (red) particles.

SAMPLE PROBLEM 5.14 | Applying Graham's Law of Effusion

Problem A mixture of helium (He) and methane (CH₄) is placed in an effusion apparatus. (a) Calculate the ratio of the effusion rates of the two gases. (b) If it takes 7.55 min for a given volume of CH₄ to effuse from the apparatus, how long will it take for the same volume of He to effuse? (c) In another experiment, helium and a second noble gas are placed into the effusion apparatus. It takes 2.05 min for 5.25 mL of helium to effuse and 6.48 min for the same volume of the unknown noble gas to effuse. What is the identity of the noble gas?

Plan (a) The effusion rate is inversely proportional to $\sqrt{\mathcal{M}}$, so we find the molar mass of each substance from the formula and take its square root. The inverse of the ratio of the square roots is the ratio of the effusion rates. (b) Once we know the ratio of effusion rates, we can apply that ratio to the time. (c) We divide the effused volume by the time to obtain an effusion rate in mL/min for both gases and then use the rearrangement of Graham's Law to find the molar mass of the unknown gas, which allows us to identify the gas.

Solution (a) $\mathcal{M}$ of CH₄ = 16.04 g/mol $\mathcal{M}$ of He = 4.003 g/mol

Calculating the ratio of the effusion rates:

$$\frac{\text{Rate}_{\text{He}}}{\text{Rate}_{\text{CH}_4}} = \sqrt{\frac{\mathcal{M}_{\text{CH}_4}}{\mathcal{M}_{\text{He}}}} = \sqrt{\frac{16.04 \text{ g/mol}}{4.003 \text{ g/mol}}} = \sqrt{4.007} = 2.002$$

A ratio of 2.002 indicates that He atoms effuse a bit more than twice as fast as CH₄ molecules under the same conditions.

(b) Since He atoms effuse twice as fast as CH₄ molecules, a volume of He will effuse in half the time it takes for an equal volume of CH₄:

$$\frac{7.55 \text{ min}}{2.002} = 3.77 \text{ min}$$

$$\text{(c) } \mathcal{M}_X = \mathcal{M}_{\text{He}} \times \left(\frac{\text{rate}_{\text{He}}}{\text{rate}_X} \right)^2 = 4.003 \text{ g/mol} \times \left(\frac{5.25 \text{ mL}/2.05 \text{ min}}{5.25 \text{ mL}/6.48 \text{ min}} \right)^2 = 40.0 \text{ g/mol}$$

The calculated molar mass is very close to that of **argon**.

Check A ratio greater than 1 makes sense, because the lighter He should effuse faster than the heavier CH₄. Because the molar mass of CH₄ is about four times the molar mass of He, He should effuse about twice as fast as CH₄ ($\sqrt{4}$) and therefore take half as long for a given volume to effuse from the apparatus. Since it takes about three times longer for the unknown noble gas to effuse (6.48 min/2.05 min = 3.2), the molar mass of the noble gas should be about 3² = 9 times the molar mass of helium: 9 × 4 g/mol = 36 g/mol, close to the molar mass of argon.

FOLLOW-UP PROBLEMS

5.14A If it takes 1.25 min for 0.010 mol of He to effuse, how long will it take for the same amount of ethane (C₂H₆) to effuse?

5.14B If 7.23 mL of an unknown gas effuses in the same amount of time as 13.8 mL of argon under the same conditions, what is the molar mass of the unknown gas?

SOME SIMILAR PROBLEMS 5.75, 5.76, 5.79, and 5.80

The Process of Diffusion Closely related to effusion is the process of gaseous **diffusion**, the movement of one gas (or fluid) through another (for example, the movement of gaseous molecules from perfume through air). Diffusion rates are also described generally by Graham's law:

$$\text{Rate of diffusion} \propto \frac{1}{\sqrt{\mathcal{M}}}$$

For two gases at equal pressures, such as NH₃ and HCl, moving through another gas or a mixture of gases, such as air, we find

$$\frac{\text{Rate}_{\text{NH}_3}}{\text{Rate}_{\text{HCl}}} = \sqrt{\frac{\mathcal{M}_{\text{HCl}}}{\mathcal{M}_{\text{NH}_3}}}$$

The reason for this dependence on molar mass is the same as for effusion rates: *lighter molecules have higher average speeds than heavier molecules, so they move farther in a given time.*

Figure 5.23 Diffusion of gases. Different gases (*black*, from the left, and *green*, from the right) move through each other in a tube and mix. For simplicity, the complex path of only one black particle is shown (in *red*). In reality, all the particles have similar paths.

If gas molecules move at hundreds of meters per second (see Figure 5.15), why does it take a second or two after you open a bottle of perfume to smell it? Although convection plays an important role in this process, another reason for the time lag is that a gas particle does not travel very far before it collides with another particle (Figure 5.23). Thus, a perfume molecule travels slowly because it collides with countless molecules in the air. The presence of so many other particles means that *diffusion rates are much lower than effusion rates*. Think about how quickly you could walk through an empty room compared to a room crowded with other moving people.

Diffusion also occurs when a gas enters a liquid (and even, to a small extent, a solid). However, the average distances between molecules are so much shorter in a liquid that collisions are much more frequent; thus, diffusion of a gas through a liquid is *much* slower than through a gas. Nevertheless, this type of diffusion is a vital process in biological systems, for example, in the movement of O_2 from lungs to blood.

The Chaotic World of Gases: Mean Free Path and Collision Frequency

Refinements of the basic kinetic-molecular theory provide a view into the chaotic molecular world of gases. Try to visualize an “average” N_2 molecule in the room you are in now. It is continually changing speed as it collides with other molecules—at one instant, going 2500 mi/h and, at another, standing still. But these extreme speeds are *much* less likely than the most probable one and those near it (see Figure 5.15). At 20°C and 1 atm pressure, the N_2 molecule is hurtling at an average speed of 470 m/s (rms speed = 510 m/s), or nearly 1100 mi/h!

Mean Free Path From a particle’s diameter, we can obtain the **mean free path**, the average distance the particle travels between collisions at a given temperature and pressure. The N_2 molecule (3.7×10^{-10} m in diameter) has a mean free path of 6.6×10^{-8} m, which means it travels an average of 180 molecular diameters before smashing into a fellow traveler. (An N_2 molecule the size of a billiard ball would travel an average of about 30 ft before hitting another molecule.) Therefore, even though gas molecules are *not* points of mass, it is still valid to assume that a gas sample *is* nearly all empty space. Mean free path is a key factor in the rate of diffusion and the rate of heat flow through a gas.

Collision Frequency Divide the most probable speed (meters per second) by the mean free path (meters per collision) and you obtain the **collision frequency**, the average number of collisions per second that each particle undergoes, whether with another particle or with the container. As you can see, the N_2 molecule experiences, on average, an enormous number of collisions every second: ◀

$$\text{Collision frequency} = \frac{4.7 \times 10^2 \text{ m/s}}{6.6 \times 10^{-8} \text{ m/collision}} = 7.0 \times 10^9 \text{ collision/s}$$

Distribution of speed (and kinetic energy) and collision frequency are essential ideas for understanding the speed of a reaction, as you’ll see in Chapter 16. And, as the Chemical Connections essay shows, many of the concepts we’ve discussed so far apply directly to our planet’s atmosphere.

Danger in a Molecular Amusement Park

To really appreciate the astounding events in the molecular world, let’s use a two-dimensional analogy to compare the N_2 molecule moving in air at 1 atm with a bumper car you are driving in an enormous amusement park ride. To match the collision frequency of the N_2 molecule, you would need to be traveling 2.8 billion mi/s (4.5 billion km/s, much faster than the speed of light!) and would smash into another bumper car every 700 yd (640 m).

An **atmosphere** is the envelope of gases that extends continuously from a planet's surface outward, thinning gradually until it is identical with outer space. A sample of clean, dry air at sea level on Earth contains 18 gases (Table B5.1). Under standard conditions, they behave nearly ideally, so volume percent equals mole percent (Avogadro's law), and the mole fraction of a component relates directly to its partial pressure (Dalton's law). Let's see how the gas laws and kinetic-molecular theory apply to our atmosphere, first with regard to variations in pressure and temperature and then as explanations of some very familiar phenomena.

The Smooth Variation in Pressure with Altitude

Because gases are compressible (Boyle's law), the pressure of the atmosphere *increases* smoothly as we approach Earth's surface, with a more rapid increase at lower altitudes (Figure B5.1, *left*). No boundary delineates the beginning of the atmosphere from the end of outer space, but the densities and compositions are identical at an altitude of about 10,000 km (6000 mi). Yet about 99% of the atmosphere's mass lies within 30 km (almost 19 mi) of the surface, and 75% lies within the lowest 11 km (almost 7 mi).

Table B5.1 Composition of Clean, Dry Air at Sea Level

Component	Mole Fraction
Nitrogen (N ₂)	0.78084
Oxygen (O ₂)	0.20946
Argon (Ar)	0.00934
Carbon dioxide (CO ₂)	0.00040
Neon (Ne)	1.818×10^{-5}
Helium (He)	5.24×10^{-6}
Methane (CH ₄)	2×10^{-6}
Krypton (Kr)	1.14×10^{-6}
Hydrogen (H ₂)	5×10^{-7}
Dinitrogen monoxide (N ₂ O)	5×10^{-7}
Carbon monoxide (CO)	1×10^{-7}
Xenon (Xe)	8×10^{-8}
Ozone (O ₃)	2×10^{-8}
Ammonia (NH ₃)	6×10^{-9}
Nitrogen dioxide (NO ₂)	6×10^{-9}
Nitrogen monoxide (NO)	6×10^{-10}
Sulfur dioxide (SO ₂)	2×10^{-10}
Hydrogen sulfide (H ₂ S)	2×10^{-10}

The Zig-Zag Variation in Temperature with Altitude

Unlike pressure, temperature does *not* change smoothly with altitude above Earth's surface. The atmosphere is classified into regions based on the direction of temperature change, and we'll start at the surface (Figure B5.1, *right*).

1. *The troposphere.* In the troposphere, which extends from the surface to between 7 km (23,000 ft) at the poles and 17 km (60,000 ft) at the equator, the temperature *drops* 7°C per kilometer to -55°C (218 K). This region contains about 80% of the total mass of the atmosphere, with 50% of the mass in the lower 5.6 km (18,500 ft). All weather occurs in this region, and nearly all, except supersonic, aircraft fly within it.

(continued)

Figure B5.1 Variations in pressure and temperature with altitude in Earth's atmosphere.

2. *The stratosphere and the ozone layer.* In the stratosphere, the temperature *rises* from -55°C to about 7°C (280 K) at 50 km. This rise is due to a variety of complex reactions—mostly involving ozone (O_3), another molecular form of oxygen—which are initiated by the absorption of solar radiation. Most high-energy radiation is absorbed by upper levels of the atmosphere, but some that reaches the stratosphere breaks O_2 into O atoms. The energetic O atoms collide with more O_2 to form O_3 :

where M is any particle that can carry away excess energy. This reaction releases heat, which is why stratospheric temperatures increase with altitude. Over 90% of atmospheric ozone remains in a thin layer within the stratosphere, its thickness varying both geographically (greatest at the poles) and seasonally (greatest in spring in the northern hemisphere and in fall in the southern). Stratospheric ozone is vital to life because it absorbs over 95% of the harmful ultraviolet (UV) solar radiation that would otherwise reach the surface. In Chapter 16, we'll discuss the destructive effect of certain industrial chemicals on the ozone layer.

3. *The mesosphere.* In the mesosphere, the temperature *drops* again to -93°C (180 K) at around 80 km.

4. *The outer atmosphere.* Within the *thermosphere*, which extends to around 500 km, the temperature *rises* again but varies between 700 and 2000 K, depending on the intensity of solar radiation and sunspot activity. The *exosphere*, the outermost region, maintains these temperatures and merges with outer space.

What does it actually mean to have a temperature of 2000 K at 500 km (300 mi) above Earth's surface? Would a piece of iron (melting point = 1808 K) glow red-hot within a minute or so and melt in the thermosphere, as it does if heated to 2000 K in the troposphere? The answer involves the relation between temperature and the time it takes to transfer kinetic energy. Our use of the words *hot* and *cold* refers to measurements near the surface. There, the collision frequency of gas particles with a thermometer is enormous, and so the transfer of their kinetic

energy is very fast. But, at an altitude of 500 km, where the density of gas particles is a million times *less*, collision frequency is extremely low, and a thermometer, or any other object, experiences *very slow transfer of kinetic energy*. Thus, the object would not become “hot” in the usual sense in any reasonable time. But the high-energy solar radiation that *is* transferred to the few particles present in these regions makes their average kinetic energy extremely high, as indicated by the high absolute temperature.

Convection in the Lower Atmosphere

Why must you take more breaths per minute on a high mountain-top than at sea level? Because at the higher elevation, there is a smaller *amount* of O_2 in each breath. However, the *proportion* (mole percent) of O_2 throughout the lower atmosphere remains about 21%. This uniform composition arises from *vertical (convective) mixing*, and the gas laws explain how it occurs.

Let's follow an air mass from ground level, as solar heating of Earth's surface warms it. The warmer air mass expands (Charles's law), which makes it less dense, so it rises. As it does so, the pressure on it decreases, making it expand further (Boyle's law). Pushing against the surrounding air requires energy, so the temperature of the air mass decreases and thus the air mass shrinks slightly (Charles's law). But, as its temperature drops, its water vapor condenses (or solidifies), and these changes of state release heat; therefore, the air mass becomes warmer and rises further. Meanwhile, the cooler, and thus denser, air that was above it sinks, becomes warmer through contact with the surface, and goes through the same process as the first air mass. As a result of this vertical mixing, the composition of the lower atmosphere remains uniform.

Warm air rising from the ground, called a *thermal*, is used by soaring birds and glider pilots to stay aloft. Convection helps clean the air in urban areas, because the rising air carries up pollutants, which are dispersed by winds. Under certain conditions, however, a warm air mass remains stationary over a cool one. The resulting *temperature inversion* blocks normal convection, and harmful pollutants build up, causing severe health problems.

Problems

B5.1 Suggest a reason supersonic aircraft are kept well below their maximum speeds until they reach their highest altitudes.

B5.2 Gases behave nearly ideally under Earth's conditions. Elsewhere in the Solar System, however, conditions are very different. On which planet would you expect atmospheric gases to deviate most from ideal behavior, Saturn (4×10^6 atm and 130 K) or Venus (90 atm and 730 K)? Explain.

B5.3 What is the volume percent and partial pressure (in torr) of argon in a sample of dry air at sea level?

B5.4 Earth's atmosphere is estimated to have a mass of 5.14×10^{15} t (1 t = 1000 kg).

(a) If the average molar mass of air is 28.8 g/mol, how many moles of gas are in the atmosphere?

(b) How many liters would the atmosphere occupy at 25°C and 1 atm?

› Summary of Section 5.5

- › The kinetic-molecular theory postulates that gas particles have no volume, move in random, straight-line paths between elastic (energy-conserving) collisions, and have average kinetic energies proportional to the absolute temperature of the gas.
- › This theory explains the gas laws in terms of changes in distances between particles and the container walls, changes in molecular speed, and the energy of collisions.
- › Temperature is a measure of the average kinetic energy of the particles.
- › Effusion and diffusion rates are *inversely* proportional to the square root of the molar mass (Graham's law), because they are *directly* proportional to molecular speed.
- › Molecular motion is characterized by a temperature-dependent, most probable speed (within a range of speeds), which affects mean free path and collision frequency.
- › The atmosphere is a complex mixture of gases that exhibits variations in pressure and temperature with altitude. High temperatures in the upper atmosphere result from absorption of high-energy solar radiation. The lower atmosphere has a uniform composition as a result of convective mixing.

5.6 REAL GASES: DEVIATIONS FROM IDEAL BEHAVIOR

A fundamental principle of science is that simpler models are more useful than complex ones, as long as they explain the data. With only a few postulates, the kinetic-molecular theory explains the behavior of most gases under ordinary conditions of temperature and pressure. But two of the postulates are useful approximations that do not reflect reality:

1. Gas particles are **not** points of mass with zero volume but have volumes determined by the sizes of their atoms and the lengths and directions of their bonds.
2. Attractive and repulsive forces **do** exist among gas particles because atoms contain charged subatomic particles and many substances are polar. (As you'll see in Chapter 12, such forces lead to changes of physical state.)

These two features cause deviations from ideal behavior under *extreme conditions of low temperature and high pressure*. These deviations mean that we must alter the simple model and the ideal gas law to predict the behavior of real gases.

Effects of Extreme Conditions on Gas Behavior

At ordinary conditions—relatively high temperatures and low pressures—most real gases exhibit nearly ideal behavior. Yet, even at STP (0°C and 1 atm), gases deviate *slightly* from ideal behavior. Table 5.3 shows that the standard molar volumes of several gases, when measured to five significant figures, do not equal the ideal value of 22.414 L/mol. Note that gases with higher boiling points exhibit greater deviations.

The phenomena that cause slight deviations under standard conditions exert more influence as temperature decreases and pressure increases. Figure 5.24 shows a plot of PV/RT versus external pressure (P_{ext}) for 1 mol of several real gases and an ideal gas. For 1 mol ($n = 1$) of an ideal gas, $PV/RT = 1$ at any P_{ext} :

$$PV = nRT \quad \text{or} \quad PV = 1(RT) \quad \text{or} \quad \frac{PV}{RT} = 1$$

The graph in Figure 5.24 shows that the PV/RT values for real gases range from the normal value of 1 at low pressure to higher values at very high pressures (at $P_{\text{ext}} \approx 1000$ atm, $PV/RT \approx 1.6$ to 2.3).

The PV/RT curve for methane (CH_4) is typical of most gases: it decreases *below* the ideal value at moderately high P_{ext} and then rises *above* the ideal value as P_{ext} increases to very high values. This shape arises from two overlapping effects:

- At moderately high P_{ext} , PV/RT values are lower than ideal values (less than 1) because of *interparticle attractions*.
- At very high P_{ext} , PV/RT values are greater than ideal values (more than 1) because of *particle volume*.

Table 5.3 Molar Volume of Some Common Gases at STP (0°C and 1 atm)

Gas	Molar Volume (L/mol)	Boiling Point (°C)
He	22.435	−268.9
H ₂	22.432	−252.8
Ne	22.422	−246.1
Ideal gas	22.414	—
Ar	22.397	−185.9
N ₂	22.396	−195.8
O ₂	22.390	−183.0
CO	22.388	−191.5
Cl ₂	22.184	−34.0
NH ₃	22.079	−33.4

Figure 5.24 Deviations from ideal behavior with increasing external pressure. The horizontal line shows that, for 1 mol of ideal gas, $PV/RT = 1$ at all P_{ext} . At very high P_{ext} , real gases deviate significantly from ideal behavior, but small deviations appear even at ordinary pressures (*expanded portion*).

Let's examine these effects on the molecular level:

1. *Effect of interparticle attractions.* Interparticle attractions occur between separate atoms or molecules and are caused by imbalances in electron distributions. They are important only over *very* short distances and are *much* weaker than the covalent bonding forces that hold a molecule together. At normal P_{ext} , the spaces between the particles are so large that attractions between the gas particles are negligible and the gas behaves nearly ideally. As conditions of pressure and temperature become more extreme, however, the interparticle attractions become more important:

- *High pressure.* As P_{ext} rises, the volume of the sample decreases and the particles get closer together, so interparticle attractions have a greater effect. As a particle approaches the container wall under these higher pressures, nearby particles attract it, which lessens the force of its impact (Figure 5.25). *Repeated throughout the sample, this effect results in decreased gas pressure and, thus, a smaller numerator in PV/RT , which results in PV/RT dropping below the expected value of 1.*
- *Low temperature.* Lowering the temperature slows the particles, so they attract each other for a longer time. (As you'll see in Chapter 12, given a low enough temperature, the interparticle attractions cause the gas particles to lose enough kinetic energy that they condense to a liquid.)

2. *Effect of particle volume.* At normal P_{ext} , the space between particles (free volume) is enormous compared with the volume of the particles *themselves* (particle volume); thus, the free volume is essentially equal to V , the container volume in PV/RT . At *moderately high* P_{ext} and as free volume decreases, the particle volume makes up an

Figure 5.25 The effect of interparticle attractions on measured gas pressure.

Figure 5.26 The effect of particle volume on measured gas volume.

increasing proportion of the container volume (Figure 5.26). At *extremely* high pressures, the space taken up by the particles themselves makes the free volume significantly *less* than the container volume. Nevertheless, we continue to use the container volume for V in PV/RT , which causes the numerator, and thus the ratio, to become artificially high. This particle volume effect increases as P_{ext} increases, eventually outweighing the effect of interparticle attractions and causing PV/RT to rise above the ideal value.

In Figure 5.24, note that the H_2 and He curves do not show the typical dip at moderate pressures. These gases consist of particles with such weak interparticle attractions that the particle volume effect predominates at all pressures.

The van der Waals Equation: Adjusting the Ideal Gas Law

To describe real gas behavior more accurately, we need to adjust the ideal gas equation in two ways:

1. Adjust P *up* by adding a factor that accounts for interparticle attractions.
2. Adjust V *down* by subtracting a factor that accounts for particle volume.

In 1873, Johannes van der Waals revised the ideal gas equation to account for the behavior of real gases. The **van der Waals equation** for n moles of a real gas is

$$\left(P + \frac{n^2 a}{V^2} \right) (V - nb) = nRT \quad (5.15)$$

adjusts adjusts
 P up V down

where P is the measured pressure, V is the known container volume, n and T have their usual meanings, and a and b are **van der Waals constants**, experimentally determined and specific for a given gas (Table 5.4). The constant a depends on the number and distribution of electrons, which relates to the complexity of a particle and the strength of its interparticle attractions. The constant b relates to particle volume. For instance, CO_2 is both more complex and larger than H_2 , and the values of their constants reflect this.

Consider the following example: a 1.98-L vessel contains 215 g (4.89 mol) of dry ice. After standing at 26°C (299 K), the $\text{CO}_2(s)$ changes to $\text{CO}_2(g)$. Let's use both the ideal gas and the van der Waals equations to calculate the pressure of the gas:

Ideal gas equation (IGL)	van der Waals equation (VDW)
$PV = nRT$ or $P = \frac{nRT}{V}$ $P = \frac{(4.89 \text{ mol}) \left(0.0821 \frac{\text{atm} \cdot \text{L}}{\text{mol} \cdot \text{K}} \right) (299 \text{ K})}{1.98 \text{ L}}$ $P_{\text{IGL}} = 60.6 \text{ atm}$	$\left(P + \frac{n^2 a}{V^2} \right) (V - nb) = nRT$ $P = \frac{nRT}{(V - nb)} - \frac{n^2 a}{V^2}$ $P = \frac{4.89 \text{ mol} \times 0.0821 \frac{\text{atm} \cdot \text{L}}{\text{mol} \cdot \text{K}} \times 299 \text{ K}}{1.98 \text{ L} - 4.89 \text{ mol} \times 0.0427 \text{ L/mol}} - \frac{(4.89 \text{ mol})^2 \times 3.59 \frac{\text{atm} \cdot \text{L}}{\text{mol}^2}}{(1.98 \text{ L})^2}$ $P_{\text{VDW}} = 45.9 \text{ atm}$

The pressure of the $\text{CO}_2(g)$ is experimentally measured (P_{real}) as 44.8 atm.

Table 5.4 Values of the van der Waals Constants for Some Common Gases

Gas	$a \left(\frac{\text{atm} \cdot \text{L}^2}{\text{mol}^2} \right)$	$b \left(\frac{\text{L}}{\text{mol}} \right)$
He	0.034	0.0237
Ne	0.211	0.0171
Ar	1.35	0.0322
Kr	2.32	0.0398
Xe	4.19	0.0511
H_2	0.244	0.0266
N_2	1.39	0.0391
O_2	1.36	0.0318
Cl_2	6.49	0.0562
CH_4	2.25	0.0428
CO	1.45	0.0395
CO_2	3.59	0.0427
NH_3	4.17	0.0371
H_2O	5.46	0.0305

Comparing the real value with each calculated value shows that P_{IGL} is 35.3% greater than P_{real} , but P_{VDW} is only 2.5% greater than P_{real} . At these conditions, CO_2 deviates so much from ideal behavior that the ideal gas law is not very useful.

A key point to realize: according to kinetic-molecular theory, the constants a and b are zero for an ideal gas because the gas particles do not attract each other and have no volume. Yet, even in a real gas at ordinary pressures, the particles are very far apart. This large average interparticle distance has two consequences:

- Attractive forces are miniscule, so $P + \frac{n^2a}{V^2} \approx P$.
- The particle volume is a minute fraction of the container volume, so $V - nb \approx V$.

Therefore, *at ordinary conditions, the van der Waals equation becomes the ideal gas equation.*

› Summary of Section 5.6

- › At very high P or low T , all gases deviate significantly from ideal behavior.
- › As external pressure increases, most real gases exhibit first a lower and then a higher PV/RT ; for 1 mol of an ideal gas, this ratio remains constant at 1.
- › The deviations from ideal behavior are due to (1) attractions between particles, which lower the pressure (and decrease PV/RT), and (2) the volume of the particles themselves, which takes up an increasingly larger fraction of the container volume (and increases PV/RT).
- › The van der Waals equation includes constants specific for a given gas to correct for deviations from ideal behavior. At ordinary P and T , the van der Waals equation reduces to the ideal gas equation.

Student Hot Spot

Student data indicate that you may struggle with the van der Waals equation. Access the eBook to view an additional Learning Resource video on this topic.

CHAPTER REVIEW GUIDE

Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

Understand These Concepts

1. How gases differ in their macroscopic properties from liquids and solids (§5.1)
2. The meaning of *pressure* and the operation of a barometer and a manometer (§5.2)
3. The relations among gas variables expressed by Boyle's, Charles's, and Avogadro's laws (§5.3)
4. How the individual gas laws are incorporated into the ideal gas law (§5.3)
5. How the ideal gas law can be used to study gas density, molar mass, and amounts of gases in reactions (§5.4)
6. The relation between the density and the temperature and pressure of a gas (§5.4)
7. The meaning of Dalton's law and the relation between partial pressure and mole fraction of a gas; how Dalton's law applies to collecting a gas over water (§5.4)
8. How the postulates of the kinetic-molecular theory are applied to explain the origin of pressure and the gas laws (§5.5)
9. The relations among molecular speed, average kinetic energy, and temperature (§5.5)
10. The meanings of *effusion* and *diffusion* and how their rates are related to molar mass (§5.5)
11. The relations among mean free path, molecular speed, and collision frequency (§5.5)

12. Why interparticle attractions and particle volume cause gases to deviate from ideal behavior at low temperatures and high pressures (§5.6)
13. How the van der Waals equation corrects the ideal gas law for extreme conditions (§5.6)

Master These Skills

1. Interconverting among the units of pressure (atm, mmHg, torr, kPa) (SP 5.1)
2. Reducing the ideal gas law to the individual gas laws (SPs 5.2–5.6)
3. Applying gas laws to choose the correct balanced chemical equation (SP 5.7)
4. Rearranging the ideal gas law to calculate gas density (SP 5.8) and molar mass of a volatile liquid (SP 5.9)
5. Calculating the mole fraction and the partial pressure of a gas in a mixture (SP 5.10)
6. Using the vapor pressure of water to correct for the amount of a gas collected over water (SP 5.11)
7. Applying stoichiometry and gas laws to calculate amounts of reactants and products (SPs 5.12, 5.13)
8. Using Graham's law to solve problems involving gaseous effusion (SP 5.14)

Key Terms

Page numbers appear in parentheses.

atmosphere (205)
Avogadro's law (210)
barometer (203)
Boyle's law (208)

Charles's law (209)
collision frequency (234)
Dalton's law of partial pressures (222)

diffusion (233)
effusion (232)
Graham's law of effusion (232)
ideal gas (207)

ideal gas law (212)
kinetic-molecular theory (227)
manometer (204)
mean free path (234)

millimeter of mercury
(mmHg) (205)
mole fraction (X) (222)
partial pressure (222)

pascal (Pa) (205)
pressure (P) (203)
rms speed (u_{rms}) (231)
standard atmosphere (atm) (205)

standard molar volume (211)
standard temperature and
pressure (STP) (211)
torr (205)

universal gas constant (R) (212)
van der Waals constants (239)
van der Waals equation (239)

Key Equations and Relationships

Page numbers appear in parentheses.

5.1 Expressing the volume-pressure relationship (Boyle's law) (208):

$$V \propto \frac{1}{P} \quad \text{or} \quad PV = \text{constant} \quad [T \text{ and } n \text{ fixed}]$$

5.2 Expressing the volume-temperature relationship
(Charles's law) (209):

$$V \propto T \quad \text{or} \quad \frac{V}{T} = \text{constant} \quad [P \text{ and } n \text{ fixed}]$$

5.3 Expressing the pressure-temperature relationship
(Amontons's law) (209):

$$P \propto T \quad \text{or} \quad \frac{P}{T} = \text{constant} \quad [V \text{ and } n \text{ fixed}]$$

5.4 Expressing the volume-amount relationship
(Avogadro's law) (210):

$$V \propto n \quad \text{or} \quad \frac{V}{n} = \text{constant} \quad [P \text{ and } T \text{ fixed}]$$

5.5 Defining standard temperature and pressure (211):

STP: 0°C (273.15 K) and 1 atm (760 torr)

5.6 Defining the volume of 1 mol of an ideal gas at STP (211):

Standard molar volume = 22.41395 L or 22.4 L [to 3 sf]

5.7 Relating volume to pressure, temperature, and amount (ideal gas law) (212):

$$PV = nRT \quad \text{and} \quad \frac{P_1 V_1}{n_1 T_1} = \frac{P_2 V_2}{n_2 T_2}$$

5.8 Calculating the value of R (212):

$$R = \frac{PV}{nT} = \frac{1 \text{ atm} \times 22.41395 \text{ L}}{1 \text{ mol} \times 273.15 \text{ K}} \\ = 0.0820573 \frac{\text{atm} \cdot \text{L}}{\text{mol} \cdot \text{K}} = 0.0821 \frac{\text{atm} \cdot \text{L}}{\text{mol} \cdot \text{K}} \quad [3 \text{ sf}]$$

5.9 Rearranging the ideal gas law to find gas density (218):

$$PV = \frac{m}{\mathcal{M}} RT \quad \text{so} \quad \frac{m}{V} = d = \frac{P \times \mathcal{M}}{RT}$$

5.10 Rearranging the ideal gas law to find molar mass (220):

$$n = \frac{m}{\mathcal{M}} = \frac{PV}{RT} \quad \text{so} \quad \mathcal{M} = \frac{mRT}{PV}$$

5.11 Relating the total pressure of a gas mixture to the
partial pressures of the components (Dalton's law of partial
pressures) (222):

$$P_{\text{total}} = P_1 + P_2 + P_3 + \cdots$$

5.12 Relating partial pressure to mole fraction (222):

$$P_A = X_A \times P_{\text{total}}$$

5.13 Defining rms speed as a function of molar mass and
temperature (231):

$$u_{\text{rms}} = \sqrt{\frac{3RT}{\mathcal{M}}}$$

5.14 Applying Graham's law of effusion (232):

$$\frac{\text{Rate}_A}{\text{Rate}_B} = \frac{\sqrt{\mathcal{M}_B}}{\sqrt{\mathcal{M}_A}} = \frac{\sqrt{\mathcal{M}_B}}{\sqrt{\mathcal{M}_A}}$$

5.15 Applying the van der Waals equation to find the pressure or
volume of a gas under extreme conditions (239):

$$\left(P + \frac{n^2 a}{V^2}\right)(V - nb) = nRT$$

CHAPTER PRACTICE TEST

The answers to the Practice Test problems are shown below and the full solutions can be found in the e-book.

1. A balloon is filled with 1.92 g of He and occupies a volume of 12.5 L. What is the balloon's volume after 0.85 g of He has leaked out though a small hole (assuming constant pressure and temperature)?

- (a) 6.95 L (b) 5.53 L (c) 22.4 L
(d) 12.5 L (e) 1.07 L

2. Aluminum reacts with chlorine gas to form aluminum chloride.

What volume of chlorine gas at 25°C and 225 mmHg is required to completely react with 7.85 g of aluminum?

- (a) 36.0 L (b) 24.0 L (c) 0.0474 L
(d) 16.0 L (e) 54.0 L

3. A mixture of gaseous S_2F_2 , N_2F_4 , and SF_4 is placed in an effusion apparatus. Rank the gases in order of increasing effusion rate.

- (a) rate S_2F_2 < rate N_2F_4 < rate SF_4
(b) rate N_2F_4 < rate S_2F_2 < rate SF_4
(c) rate SF_4 < rate S_2F_2 < rate N_2F_4

(d) rate SF_4 = rate N_2F_4 < rate S_2F_2

(e) rate SF_4 < rate N_2F_4 < rate S_2F_2

4. A 1200. mL sample of helium gas is at a pressure of 350. mmHg and a temperature of 27°C. What volume will this gas sample occupy if the pressure is increased to 700. mmHg and the temperature is increased to 127°C?

- (a) 400 mL (b) 800 mL (c) 2820 mL
(d) 3000 mL (e) 450 mL

5. At the same temperature and pressure, CH_4 effuses

- (a) one-half as fast as SO_2 (b) two times as fast as SO_2
(c) at the same rate as SO_2 (d) one-fourth as fast as SO_2
(e) four times as fast as SO_2

6. A sealed container containing 8.0 g of O_2 gas and 11 g of CO_2 gas is kept at a constant temperature and pressure. Which **two** of the following are true?

- (a) The average kinetic energy of the two gases is the same.
(b) The volume occupied by CO_2 is greater than the volume occupied by O_2 .
(c) The density of O_2 gas is greater than the density of CO_2 .
(d) The average molecular speeds of the two gases are the same.
(e) The partial pressures of the two gases are the same.

CHAPTER PRACTICE TEST (continued)

7. A flask contains two gases with a total pressure of 2000. mmHg. There are 6.0 mol of helium with a partial pressure of 1500 mmHg, and the remaining gas is H₂. What is the mass of H₂ in the flask?

- (a) 0.50 g (b) 2.0 g (c) 4.0 g
(d) 8.0 g (e) 16 g

8. A 28.3-mL volume of hydrochloric acid was reacted completely with aqueous sodium carbonate according to the reaction

The volume of carbon dioxide produced was 163 mL at 24°C and 0.980 atm. What was the molarity of the HCl solution used?

- (a) 0.231 M (b) 0.463 M (c) 0.926 M
(d) 2.92 M (e) 5.73 M

9. A sample of 35.1 g of methane gas, CH₄, has a volume of 5.20 L at a pressure of 2.70 atm. Calculate the temperature of the gas.

- (a) 78.1°C (b) -227°C
(c) 46.3°C (d) -195°C
(e) 275°C (f) -129°C

10. When the Kelvin temperature of 1.0 L of gas is doubled and its pressure is tripled, its volume will then be

- (a) 0.17 L (b) 0.67 L
(c) 1.5 L (d) 6.0 L
(e) 4.0 L (f) 0.50 L

Answers: 1. a; 2. a; 3. e; 4. b; 5. b; 6. a, e; 7. c; 8. b; 9. d; 10. b

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

$$\begin{aligned} 5.1A \quad P_{\text{CO}_2}(\text{torr}) &= P_{\text{atm}} - \Delta h \\ &= (753.6 \text{ mmHg} - 174.0 \text{ mmHg}) \times \frac{1 \text{ torr}}{1 \text{ mmHg}} \\ &= 579.6 \text{ torr} \end{aligned}$$

$$\begin{aligned} P_{\text{CO}_2}(\text{Pa}) &= 579.6 \text{ torr} \times \frac{1 \text{ atm}}{760 \text{ torr}} \times \frac{1.01325 \times 10^5 \text{ Pa}}{1 \text{ atm}} \\ &= 7.727 \times 10^4 \text{ Pa} \end{aligned}$$

$$\begin{aligned} P_{\text{CO}_2}(\text{lb/in}^2) &= 579.6 \text{ torr} \times \frac{1 \text{ atm}}{760 \text{ torr}} \times \frac{14.696 \text{ lb/in}^2}{1 \text{ atm}} \\ &= 11.2 \text{ lb/in}^2 \end{aligned}$$

$$5.1B \quad P_{\text{atm}}(\text{torr}) = 0.9475 \text{ atm} \times \frac{760 \text{ torr}}{1 \text{ atm}} = 720.1 \text{ torr}$$

$$\begin{aligned} P_{\text{CO}_2}(\text{mmHg}) &= P_{\text{atm}} + \Delta h \\ &= (720.1 \text{ torr} + 25.8 \text{ torr}) \times \frac{1 \text{ mmHg}}{1 \text{ torr}} \\ &= 745.9 \text{ mmHg} \end{aligned}$$

$$\begin{aligned} P_{\text{CO}_2}(\text{Pa}) &= 745.9 \text{ mmHg} \times \frac{1 \text{ atm}}{760 \text{ mmHg}} \times \frac{1.01325 \times 10^5 \text{ Pa}}{1 \text{ atm}} \\ &= 9.945 \times 10^4 \text{ Pa} \end{aligned}$$

$$\begin{aligned} P_{\text{CO}_2}(\text{lb/in}^2) &= 745.9 \text{ mmHg} \times \frac{1 \text{ atm}}{760 \text{ mmHg}} \times \frac{14.696 \text{ lb/in}^2}{1 \text{ atm}} \\ &= 14.4 \text{ lb/in}^2 \end{aligned}$$

$$5.2A \quad P_2(\text{atm}) = 745 \text{ mmHg} \times \frac{1 \text{ atm}}{760 \text{ mmHg}} = 0.980 \text{ atm}$$

$$V_2 = V_1 \times \frac{P_1}{P_2}$$

$$V_2(\text{L}) = 651 \text{ L} \times \frac{122 \text{ atm}}{0.980 \text{ atm}} = 8.10 \times 10^4 \text{ L}$$

$$5.2B \quad P_2 = P_1 \times \frac{V_1}{V_2}$$

$$P_2(\text{atm}) = 0.871 \text{ atm} \times \frac{105 \text{ mL}}{352 \text{ mL}} = 0.260 \text{ atm}$$

$$P_2(\text{kPa}) = 0.260 \text{ atm} \times \frac{101.325 \text{ kPa}}{1 \text{ atm}} = 26.3 \text{ kPa}$$

$$5.3A \quad P_1(\text{torr}) = 0.991 \text{ atm} \times \frac{760 \text{ torr}}{1 \text{ atm}} = 753 \text{ torr}$$

$$P_2 = P_1 \times \frac{T_2}{T_1} = 753 \text{ torr} \times \frac{373 \text{ K}}{296 \text{ K}} = 949 \text{ torr}$$

$$P_2 < 1.00 \times 10^3 \text{ torr, so the safety valve will not open.}$$

$$5.3B \quad T_2(\text{K}) = T_1 \times \frac{V_2}{V_1} = 313 \text{ K} \times \frac{28.6 \text{ L}}{32.5 \text{ L}} = 275 \text{ K}$$

$$T_2(^{\circ}\text{C}) = 275 \text{ K} - 273.15 = 2^{\circ}\text{C}$$

$$5.4A \quad P_2(\text{torr}) = P_1 \times \frac{n_2}{n_1} = 793 \text{ torr} \times \frac{35.0 \text{ g} - 5.0 \text{ g}}{35.0 \text{ g}} = 680. \text{ torr}$$

(There is no need to convert mass to moles because the ratio of masses equals the ratio of moles.)

$$\begin{aligned} 5.4B \quad \text{Amount (mol) of N}_2 &= 1.26 \text{ g N}_2 \times \frac{1 \text{ mol N}_2}{28.02 \text{ g N}_2} \\ &= 0.0450 \text{ mol N}_2 \end{aligned}$$

$$\text{Amount (mol) of He} = 1.26 \text{ g He} \times \frac{1 \text{ mol He}}{4.003 \text{ g He}} = 0.315 \text{ mol He}$$

$$V_2 = V_1 \times \frac{n_2}{n_1} = 1.12 \text{ L} \times \frac{0.0450 \text{ mol} + 0.315 \text{ mol}}{0.0450 \text{ mol}} = 8.96 \text{ L}$$

5.5A

$$\begin{aligned} P_2(\text{mmHg}) &= P_1 \times \frac{V_1 T_2}{V_2 T_1} = 755 \text{ mmHg} \times \frac{(2.55 \text{ L})(291 \text{ K})}{(4.10 \text{ L})(296 \text{ K})} \\ &= 462 \text{ mmHg} \end{aligned}$$

$$\begin{aligned} 5.5B \quad V_2(\text{L}) &= V_1 \times \frac{P_1 T_2}{P_2 T_1} = 2.2 \text{ L} \times \frac{(0.980 \text{ atm})(294 \text{ K})}{(1.40 \text{ atm})(301 \text{ K})} \\ &= 1.5 \text{ L} \end{aligned}$$

$$5.6A \quad n = \frac{PV}{RT} = \frac{1.37 \text{ atm} \times 438 \text{ L}}{0.0821 \frac{\text{atm} \cdot \text{L}}{\text{mol} \cdot \text{K}} \times 294 \text{ K}} = 24.9 \text{ mol O}_2$$

$$\text{Mass (g) of O}_2 = 24.9 \text{ mol O}_2 \times \frac{32.00 \text{ g O}_2}{1 \text{ mol O}_2} = 7.97 \times 10^2 \text{ g O}_2$$

5.6B

$$\begin{aligned} \text{Amount (mol) of He} &= 3950 \text{ kg He} \times \frac{1000 \text{ g}}{1 \text{ kg}} \times \frac{1 \text{ mol He}}{4.003 \text{ g He}} \\ &= 9.87 \times 10^5 \text{ mol He} \end{aligned}$$

$$V = \frac{nRT}{P} = \frac{9.87 \times 10^5 \text{ mol} \times 0.0821 \frac{\text{atm} \cdot \text{L}}{\text{mol} \cdot \text{K}} \times 293 \text{ K}}{731 \text{ mmHg} \times \frac{1 \text{ atm}}{760 \text{ mmHg}}} = 2.47 \times 10^7 \text{ L}$$

5.7A The balanced equation is $2\text{CD}(g) \longrightarrow \text{C}_2(g) + \text{D}_2(g)$, so n does not change. The volume has doubled. Therefore, given constant P , the temperature, T , must also double: $T_1 = -73^{\circ}\text{C} + 273.15 = 200 \text{ K}$; so $T_2 = 400 \text{ K}$, or $400 \text{ K} - 273.15 = 127^{\circ}\text{C}$.

$$\begin{aligned} 5.7B \quad T_1 &= 199^\circ\text{C} + 273.15 = 472 \text{ K} \\ T_2 &= -155^\circ\text{C} + 273.15 = 118 \text{ K} \end{aligned}$$

Temperature has been reduced by $\frac{1}{4}$; if n were constant, V would also be reduced by $\frac{1}{4}$. But, since V has been halved, n must be doubled. The number of moles of gas doubles (from 2 mol to 4 mol) in equation (2).

5.8A

$$\begin{aligned} d \text{ (at } 0^\circ\text{C and } 380 \text{ torr)} &= \frac{P\mathcal{M}}{RT} = \frac{380 \text{ torr}}{760 \text{ torr/atm}} \times \frac{44.01 \text{ g/mol}}{0.0821 \frac{\text{atm}\cdot\text{L}}{\text{mol}\cdot\text{K}} \times 273 \text{ K}} \\ &= 0.982 \text{ g/L} \end{aligned}$$

The density is lower at the smaller P because V is larger. In this case, d is lowered by $\frac{1}{2}$ because P is $\frac{1}{2}$ as much.

5.8B

$$\begin{aligned} d \text{ (at } 24^\circ\text{C and } 0.950 \text{ atm)} &= \frac{P\mathcal{M}}{RT} = \frac{0.950 \text{ atm} \times 46.01 \text{ g/mol}}{0.0821 \frac{\text{atm}\cdot\text{L}}{\text{mol}\cdot\text{K}} \times 297 \text{ K}} \\ &= 1.79 \text{ g/L} \end{aligned}$$

NO_2 is more dense than dry air.

$$5.9A \quad \text{Mass of gas} = 68.697 \text{ g} - 68.322 \text{ g} = 0.375 \text{ g}$$

$$\begin{aligned} \mathcal{M} &= \frac{mRT}{PV} = \frac{0.375 \text{ g} \times 0.0821 \frac{\text{atm}\cdot\text{L}}{\text{mol}\cdot\text{K}} \times (273.15 + 95.0) \text{ K}}{\frac{740. \text{ torr}}{760 \text{ torr/atm}} \times \frac{149 \text{ mL}}{1000 \text{ mL/L}}} \\ &= 78.1 \text{ g/mol} \end{aligned}$$

$$5.9B \quad \text{Mass of gas} = 82.786 \text{ g} - 82.561 \text{ g} = 0.225 \text{ g}$$

$$\begin{aligned} \mathcal{M} &= \frac{mRT}{PV} = \frac{0.225 \text{ g} \times 0.0821 \frac{\text{atm}\cdot\text{L}}{\text{mol}\cdot\text{K}} \times (273.15 + 22) \text{ K}}{\frac{733 \text{ mmHg}}{760 \text{ mmHg/atm}} \times \frac{350. \text{ mL}}{1000 \text{ mL/L}}} \\ &= 16.1 \text{ g/mol} \end{aligned}$$

This is the molar mass of CH_4 .

$$5.10A \quad X_{^{18}\text{O}_2} = \frac{4.0 \text{ mol}\% \text{ } ^{18}\text{O}_2}{100} = 0.040$$

$$P_{^{18}\text{O}_2} = X_{^{18}\text{O}_2} \times P_{\text{total}} = 0.040 \times 0.75 \text{ atm} = 0.030 \text{ atm}$$

$$5.10B \quad X_{\text{He}} = \frac{P_{\text{He}}}{P_{\text{total}}} = \frac{143 \text{ atm}}{204 \text{ atm}} = 0.701$$

$$\text{Mole } \% \text{ He} = 0.701 \times 100 = 70.1\%$$

$$5.11A \quad P_{\text{H}_2} \text{ (torr)} = P_{\text{total}} - P_{\text{H}_2\text{O}} = 752 \text{ torr} - 13.64 \text{ torr} = 738 \text{ torr}$$

$$P_{\text{H}_2} \text{ (atm)} = 738 \text{ torr} \times \frac{1 \text{ atm}}{760 \text{ torr}} = 0.971 \text{ atm}$$

$$n_{\text{H}_2} = \frac{PV}{RT} = \frac{0.971 \text{ atm} \times 1.495 \text{ L}}{0.0821 \frac{\text{atm}\cdot\text{L}}{\text{mol}\cdot\text{K}} \times 289 \text{ K}} = 0.0612 \text{ mol H}_2$$

$$\text{Mass (g) of H}_2 = 0.0612 \text{ mol H}_2 \times \frac{2.016 \text{ g H}_2}{1 \text{ mol H}_2} = 0.123 \text{ g H}_2$$

$$5.11B \quad P_{\text{O}_2} = P_{\text{total}} - P_{\text{H}_2\text{O}} = 748 \text{ torr} - 17.55 \text{ torr} = 730. \text{ torr}$$

$$P_{\text{O}_2} \text{ (atm)} = 730. \text{ torr} \times \frac{1 \text{ atm}}{760 \text{ torr}} = 0.961 \text{ atm}$$

$$n_{\text{O}_2} = \frac{PV}{RT} = \frac{0.961 \text{ atm} \times 0.307 \text{ L}}{0.0821 \frac{\text{atm}\cdot\text{L}}{\text{mol}\cdot\text{K}} \times 293 \text{ K}} = 0.0123 \text{ mol O}_2$$

$$\text{Mass (g) of O}_2 = 0.0123 \text{ mol O}_2 \times \frac{32.00 \text{ g O}_2}{1 \text{ mol O}_2} = 0.394 \text{ g O}_2$$

$$\begin{aligned} n_{\text{CO}} &= \frac{PV}{RT} = \frac{0.975 \text{ atm} \times 44.8 \text{ L}}{0.0821 \frac{\text{atm}\cdot\text{L}}{\text{mol}\cdot\text{K}} \times 298 \text{ K}} \\ &= 1.79 \text{ mol CO} \end{aligned}$$

$$\begin{aligned} \text{Mass (g) of SiO}_2 &= 1.79 \text{ mol CO} \times \frac{1 \text{ mol SiO}_2}{2 \text{ mol CO}} \times \frac{60.08 \text{ g SiO}_2}{1 \text{ mol SiO}_2} \\ &= 53.8 \text{ g} \end{aligned}$$

$$n_{\text{H}_2} = 35.5 \text{ g CuO} \times \frac{1 \text{ mol CuO}}{79.55 \text{ g CuO}} \times \frac{1 \text{ mol H}_2}{1 \text{ mol CuO}} = 0.446 \text{ mol H}_2$$

$$V = \frac{nRT}{P} = \frac{0.446 \text{ mol} \times 0.0821 \frac{\text{atm}\cdot\text{L}}{\text{mol}\cdot\text{K}} \times 498 \text{ K}}{765 \text{ torr} \times \frac{1 \text{ atm}}{760 \text{ torr}}} = 18.1 \text{ L}$$

$$n_{\text{NH}_3} = \frac{PV}{RT} = \frac{0.452 \text{ atm} \times 10.0 \text{ L}}{0.0821 \frac{\text{atm}\cdot\text{L}}{\text{mol}\cdot\text{K}} \times 295 \text{ K}} = 0.187 \text{ mol NH}_3$$

$$n_{\text{HCl}} = \frac{PV}{RT} = \frac{7.50 \text{ atm} \times 0.155 \text{ L}}{0.0821 \frac{\text{atm}\cdot\text{L}}{\text{mol}\cdot\text{K}} \times 271 \text{ K}} = 0.0522 \text{ mol HCl}$$

$n_{\text{NH}_3} = 0.187 \text{ mol}$ and $n_{\text{HCl}} = 0.0522 \text{ mol}$; thus, HCl is the limiting reactant.

n_{NH_3} after reaction

$$\begin{aligned} &= 0.187 \text{ mol NH}_3 - \left(0.0522 \text{ mol HCl} \times \frac{1 \text{ mol NH}_3}{1 \text{ mol HCl}} \right) \\ &= 0.135 \text{ mol NH}_3 \end{aligned}$$

$$P = \frac{nRT}{V} = \frac{0.135 \text{ mol} \times 0.0821 \frac{\text{atm}\cdot\text{L}}{\text{mol}\cdot\text{K}} \times 295 \text{ K}}{10.0 \text{ L}} = 0.327 \text{ atm}$$

For I_2 :

$$\begin{aligned} \text{Amount (mol) of IF}_5 &= 4.16 \text{ g I}_2 \times \frac{1 \text{ mol I}_2}{253.8 \text{ g I}_2} \times \frac{2 \text{ mol IF}_5}{1 \text{ mol I}_2} \\ &= 0.0328 \text{ mol IF}_5 \end{aligned}$$

For F_2 :

$$n_{\text{F}_2} = \frac{PV}{RT} = \frac{0.974 \text{ atm} \times 2.48 \text{ L}}{0.0821 \frac{\text{atm}\cdot\text{L}}{\text{mol}\cdot\text{K}} \times 291 \text{ K}} = 0.101 \text{ mol F}_2$$

$$\begin{aligned} \text{Amount (mol) of IF}_5 &= 0.101 \text{ mol F}_2 \times \frac{2 \text{ mol IF}_5}{5 \text{ mol F}_2} \\ &= 0.0404 \text{ mol IF}_5 \end{aligned}$$

Thus, I_2 is the limiting reactant.

$$\begin{aligned} \text{Volume (L) of IF}_5 &= \frac{nRT}{P} = \frac{0.0328 \text{ mol} \times 0.0821 \frac{\text{atm}\cdot\text{L}}{\text{mol}\cdot\text{K}} \times 378 \text{ K}}{0.935 \text{ atm}} \\ &= 1.09 \text{ L} \end{aligned}$$

$$5.14A \quad \frac{\text{Rate of He}}{\text{Rate of C}_2\text{H}_6} = \sqrt{\frac{30.07 \text{ g/mol}}{4.003 \text{ g/mol}}} = 2.741$$

$$\text{Time for C}_2\text{H}_6 \text{ to effuse} = 1.25 \text{ min} \times 2.741 = 3.43 \text{ min}$$

$$\begin{aligned} 5.14B \quad \mathcal{M} \text{ of unknown gas} &= \mathcal{M}_{\text{Ar}} \times \left(\frac{\text{rate of Ar}}{\text{rate of unknown gas}} \right)^2 \\ &= \left(\frac{13.8 \text{ mL/time}}{7.23 \text{ mL/time}} \right)^2 \times 39.95 \text{ g/mol} \\ &= 146 \text{ g/mol} \end{aligned}$$

PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

An Overview of the Physical States of Matter

Concept Review Questions

5.1 How does a sample of gas differ in its behavior from a sample of liquid in each of the following situations?

- The sample is transferred from one container to a larger one.
- The sample is heated in an expandable container, but no change of state occurs.
- The sample is placed in a cylinder with a piston, and an external force is applied.

5.2 Are the particles in a gas farther apart or closer together than the particles in a liquid? Use your answer to explain each of the following general observations:

- Gases are more compressible than liquids.
- Gases have lower viscosities than liquids.
- After thorough stirring, all gas mixtures are solutions.
- The density of a substance in the gas state is lower than in the liquid state.

Gas Pressure and Its Measurement

(Sample Problem 5.1)

Concept Review Questions

5.3 How does a barometer work? Is the column of mercury in a barometer shorter when it is on a mountaintop or at sea level? Explain.

5.4 How can a unit of length such as millimeter of mercury (mmHg) be used as a unit of pressure, which has the dimensions of force per unit area?

5.5 In a closed-end manometer, the mercury level in the arm attached to the flask can never be higher than the mercury level in the other arm, whereas in an open-end manometer, it *can* be higher. Explain.

Skill-Building Exercises (grouped in similar pairs)

5.6 On a cool, rainy day, the barometric pressure is 730 mmHg. Calculate the barometric pressure in centimeters of water (cmH₂O) (d of Hg = 13.5 g/mL; d of H₂O = 1.00 g/mL).

5.7 A long glass tube, sealed at one end, has an inner diameter of 10.0 mm. The tube is filled with water and inverted into a pail of water. If the atmospheric pressure is 755 mmHg, how high (in mmH₂O) is the column of water in the tube (d of Hg = 13.5 g/mL; d of H₂O = 1.00 g/mL)?

5.8 Convert the following:

- 0.745 atm to mmHg
- 992 torr to bar
- 365 kPa to atm
- 804 mmHg to kPa

5.9 Convert the following:

- 76.8 cmHg to atm
- 27.5 atm to kPa
- 6.50 atm to bar
- 0.937 kPa to torr

5.10 In Figure P5.10, what is the pressure of the gas in the flask (in atm) if the barometer reads 738.5 torr?

5.11 In Figure P5.11, what is the pressure of the gas in the flask (in kPa) if the barometer reads 765.2 mmHg?

Figure P5.10

Figure P5.11

5.12 If the sample flask in Figure P5.12 is open to the air, what is the atmospheric pressure (in atm)?

5.13 In Figure P5.13, what is the pressure (in Pa) of the gas in the flask?

Figure P5.12

Figure P5.13

Problems in Context

5.14 Convert each of the pressures described below to atm:

- At the peak of Mt. Everest, atmospheric pressure is only 2.75×10^2 mmHg.
- A cyclist fills her bike tires to 86 psi.
- The surface of Venus has an atmospheric pressure of 9.15×10^6 Pa.
- At 100 ft below sea level, a scuba diver experiences a pressure of 2.54×10^4 torr.

5.15 The gravitational force exerted by an object is given by $F = mg$, where F is the force in newtons, m is the mass in kilograms, and g is the acceleration due to gravity (9.81 m/s^2).

- Use the definition of the pascal to calculate the mass (in kg) of the atmosphere above 1 m^2 of ocean.
- Osmium ($Z = 76$) is a transition metal in Group 8 and has the highest density of any element (22.6 g/mL). If an osmium column is 1 m^2 in area, how high must it be for its pressure to equal atmospheric pressure? [Use the answer from part (a) in your calculation.]

The Gas Laws and Their Experimental Foundations

(Sample Problems 5.2 to 5.7)

Concept Review Questions

5.16 A student states Boyle's law as follows: "The volume of a gas is inversely proportional to its pressure." How is this statement incomplete? Give a correct statement of Boyle's law.

5.17 In the following relationships, which quantities are variables and which are fixed: (a) Charles's law; (b) Avogadro's law; (c) Amontons's law?

5.18 Boyle's law relates gas volume to pressure, and Avogadro's law relates gas volume to amount (mol). State a relationship between gas pressure and amount (mol).

5.19 Each of the following processes caused the gas volume to double, as shown. For each process, tell how the remaining gas variable changed or state that it remained fixed:

(a) T doubles at fixed P .

(b) T and n are fixed.

(c) At fixed T , the reaction is $\text{CD}_2(\text{g}) \longrightarrow \text{C}(\text{g}) + \text{D}_2(\text{g})$.

(d) At fixed P , the reaction is $\text{A}_2(\text{g}) + \text{B}_2(\text{g}) \longrightarrow 2\text{AB}(\text{g})$.

Skill-Building Exercises (grouped in similar pairs)

5.20 What is the effect of the following on the volume of 1 mol of an ideal gas?

(a) The pressure is tripled (at constant T).

(b) The absolute temperature is increased by a factor of 3.0 (at constant P).

(c) Three more moles of the gas is added (at constant P and T).

5.21 What is the effect of the following on the volume of 1 mol of an ideal gas?

(a) The pressure changes from 760 torr to 202 kPa, and the temperature changes from 37°C to 155 K .

(b) The temperature changes from 305 K to 32°C , and the pressure changes from 2 atm to 101 kPa.

(c) The pressure is reduced by a factor of 4 (at constant T).

5.22 What is the effect of the following on the volume of 1 mol of an ideal gas?

(a) Temperature decreases from 800 K to 400 K (at constant P).

(b) Temperature increases from 250°C to 500°C (at constant P).

(c) Pressure increases from 2 atm to 6 atm (at constant T).

5.23 What is the effect of the following on the volume of 1 mol of an ideal gas?

(a) The initial pressure is 722 torr, and the final pressure is 0.950 atm; the initial temperature is 32°F , and the final temperature is 273 K.

(b) Half the gas escapes (at constant P and T).

(c) Both the pressure and temperature decrease to $\frac{1}{4}$ of their initial values.

5.24 A weather balloon is filled with helium to a volume of 1.61 L at 734 torr. What is the volume of the balloon after it has been released and its pressure has dropped to 0.844 atm? Assume that the temperature remains constant.

5.25 A sample of methane is placed in a 10.0-L container at 25°C and 725 mmHg. The gas sample is then moved to a 7.50-L container at 25°C . What is the gas pressure in the second container?

5.26 A sample of sulfur hexafluoride gas occupies 9.10 L at 198°C . Assuming that the pressure remains constant, what temperature (in $^\circ\text{C}$) is needed to reduce the volume to 2.50 L?

5.27 A 93-L sample of dry air cools from 145°C to -22°C while the pressure is maintained at 2.85 atm. What is the final volume?

5.28 A gas cylinder is filled with argon at a pressure of 177 atm and 25°C . What is the gas pressure when the temperature of the cylinder and its contents are heated to 195°C by exposure to fire?

5.29 A bicycle tire is filled to a pressure of 110. psi at a temperature of 30.0°C . At what temperature will the air pressure in the tire decrease to 105 psi? Assume that the volume of the tire remains constant.

5.30 A balloon filled with 1.92 g of helium has a volume of 12.5 L. What is the balloon's volume after 0.850 g of helium has leaked out through a small hole (assume constant pressure and temperature)?

5.31 The average person takes 500 mL of air into the lungs with each normal inhalation, which corresponds to approximately 1×10^{22} molecules of air. Calculate the number of molecules of air inhaled by a person with a respiratory problem who takes in only 350 mL of air with each breath. Assume constant pressure and temperature.

5.32 A sample of Freon-12 (CF_2Cl_2) occupies 25.5 L at 298 K and 153.3 kPa. Find its volume at STP.

5.33 A sample of carbon monoxide occupies 3.65 L at 298 K and 745 torr. Find its volume at -14°C and 367 torr.

5.34 A sample of chlorine gas is confined in a 5.0-L container at 328 torr and 37°C . How many moles of gas are in the sample?

5.35 If 1.47×10^{-3} mol of argon occupies a 75.0-mL container at 26°C , what is the pressure (in torr)?

5.36 You have 357 mL of chlorine trifluoride gas at 699 mmHg and 45°C . What is the mass (in g) of the sample?

5.37 A 75.0-g sample of dinitrogen monoxide is confined in a 3.1-L vessel. What is the pressure (in atm) at 115°C ?

Problems in Context

5.38 In preparation for a demonstration, your professor brings a 1.5-L bottle of sulfur dioxide into the lecture hall before class to allow the gas to reach room temperature. If the pressure gauge reads 85 psi and the temperature in the classroom is 23°C , how many moles of sulfur dioxide are in the bottle? (*Hint:* The gauge reads zero when the gas pressure in the bottle is 14.7 psi.)

5.39 A gas-filled weather balloon with a volume of 65.0 L is released at sea-level conditions of 745 torr and 25°C . The balloon can expand to a maximum volume of 835 L. When the balloon rises to an altitude at which the temperature is -5°C and the pressure is 0.066 atm, will it have expanded to its maximum volume?

Rearrangements of the Ideal Gas Law

(Sample Problems 5.8 to 5.13)

Concept Review Questions

5.40 Why is moist air less dense than dry air?

5.41 To collect a beaker of H_2 gas by displacing the air already in the beaker, would you hold the beaker upright or inverted? Why? How would you hold the beaker to collect CO_2 ?

5.42 Why can we use a gas mixture, such as air, to study the general behavior of an ideal gas under ordinary conditions?

5.43 How does the partial pressure of gas A in a mixture compare to its mole fraction in the mixture? Explain.

5.44 The scene at right represents a portion of a mixture of four gases A (purple), B (black), C (green), and D₂ (orange). (a) Which gas has the highest partial pressure? (b) Which has the lowest partial pressure? (c) If the total pressure is 0.75 atm, what is the partial pressure of D₂?

Skill-Building Exercises (grouped in similar pairs)**5.45** What is the density of Xe gas at STP?**5.46** Find the density of Freon-11 (CFCl_3) at 120°C and 1.5 atm.**5.47** How many moles of gaseous arsine (AsH_3) occupy 0.0400 L at STP? What is the density of gaseous arsine?**5.48** The density of a noble gas is 2.71 g/L at 3.00 atm and 0°C . Identify the gas.**5.49** Calculate the molar mass of a gas at 388 torr and 45°C if 206 ng occupies 0.206 μL .**5.50** When an evacuated 63.8-mL glass bulb is filled with a gas at 22°C and 747 mmHg, the bulb gains 0.103 g in mass. Is the gas N_2 , Ne, or Ar?**5.51** After 0.600 L of Ar at 1.20 atm and 227°C is mixed with 0.200 L of O_2 at 501 torr and 127°C in a 400-mL flask at 27°C , what is the pressure in the flask?**5.52** A 355-mL container holds 0.146 g of Ne and an unknown amount of Ar at 35°C and a total pressure of 626 mmHg. Calculate the number of moles of Ar present.**5.53** How many grams of phosphorus react with 35.5 L of O_2 at STP to form tetraphosphorus decoxide?**5.54** How many grams of potassium chlorate decompose to potassium chloride and 638 mL of O_2 at 128°C and 752 torr?**5.55** How many grams of phosphine (PH_3) can form when 37.5 g of phosphorus and 83.0 L of hydrogen gas react at STP?**5.56** When 35.6 L of ammonia and 40.5 L of oxygen gas at STP burn, nitrogen monoxide and water form. After the products return to STP, how many grams of nitrogen monoxide are present?**5.57** Aluminum reacts with excess hydrochloric acid to form aqueous aluminum chloride and 35.8 mL of hydrogen gas over water at 27°C and 751 mmHg. How many grams of aluminum react?**5.58** How many liters of hydrogen gas are collected over water at 18°C and 725 mmHg when 0.84 g of lithium reacts with water? Aqueous lithium hydroxide also forms.**Problems in Context****5.59** The air in a hot-air balloon at 744 torr is heated from 17°C to 60.0°C . Assuming that the amount (mol) of air and the pressure remain constant, what is the density of the air at each temperature? (The average molar mass of air is 28.8 g/mol.)**5.60** On a certain winter day in Utah, the average atmospheric pressure is 650. torr. What is the molar density (in mol/L) of the air if the temperature is -25°C ?**5.61** A sample of a liquid hydrocarbon known to consist of molecules with five carbon atoms is vaporized in a 0.204-L flask by immersion in a water bath at 101°C . The barometric pressure is 767 torr, and the remaining gas weighs 0.482 g. What is the molecular formula of the hydrocarbon?**5.62** A sample of air contains 78.08% nitrogen, 20.94% oxygen, 0.05% carbon dioxide, and 0.93% argon, by volume. How many molecules of each gas are present in 1.00 L of the sample at 25°C and 1.00 atm?**5.63** An environmental chemist sampling industrial exhaust gases from a coal-burning plant collects a CO_2 - SO_2 - H_2O mixture in a 21-L steel tank until the pressure reaches 850. torr at 45°C .

(a) How many moles of gas are collected?

(b) If the SO_2 concentration in the mixture is 7.95×10^3 parts per million by volume (ppmv), what is its partial pressure? [Hint: $\text{ppmv} = (\text{volume of component} / \text{volume of mixture}) \times 10^6$.]**5.64** “Strike anywhere” matches contain the compound tetraphosphorus trisulfide, which burns to form tetraphosphorus decoxide and sulfur dioxide gas. How many milliliters of sulfur dioxide, measured at 725 torr and 32°C , can be produced from burning 0.800 g of tetraphosphorus trisulfide?**5.65** Freon-12 (CF_2Cl_2), widely used as a refrigerant and aerosol propellant, is a dangerous air pollutant. In the troposphere, it traps heat 25 times as effectively as CO_2 , and, in the stratosphere, it participates in the breakdown of ozone. Freon-12 is prepared industrially by reaction of gaseous carbon tetrachloride with hydrogen fluoride. Hydrogen chloride gas also forms. How many grams of carbon tetrachloride are required for the production of 16.0 dm^3 of Freon-12 at 27°C and 1.20 atm?**5.66** Xenon hexafluoride was one of the first noble gas compounds synthesized. The solid reacts rapidly with the silicon dioxide in glass or quartz containers to form liquid XeOF_4 and gaseous silicon tetrafluoride. What is the pressure in a 1.00-L container at 25°C after 2.00 g of xenon hexafluoride reacts? (Assume that silicon tetrafluoride is the only gas present and that it occupies the entire volume.)**5.67** In the four piston-cylinder assemblies below, the reactant in the left cylinder is about to undergo a reaction at constant T and P :

Which of the other three depictions best represents the products of the reaction?

5.68 Roasting galena [lead(II) sulfide] is a step in the industrial isolation of lead. How many liters of sulfur dioxide, measured at STP, are produced by the reaction of 3.75 kg of galena with 228 L of oxygen gas at 220°C and 2.0 atm? Lead(II) oxide also forms.**5.69** In one of his most critical studies on the nature of combustion, Lavoisier heated mercury(II) oxide and isolated elemental mercury and oxygen gas. If 40.0 g of mercury(II) oxide is heated in a 502-mL vessel and 20.0% (by mass) decomposes, what is the pressure (in atm) of the oxygen that forms at 25.0°C ? (Assume that the gas occupies the entire volume.)**The Kinetic-Molecular Theory: A Model for Gas Behavior**
(Sample Problem 5.14)**Concept Review Questions****5.70** Use the kinetic-molecular theory to explain the change in gas pressure that results from warming a sample of gas.**5.71** How does the kinetic-molecular theory explain why 1 mol of krypton and 1 mol of helium have the same volume at STP?

5.72 Is the rate of effusion of a gas higher than, lower than, or equal to its rate of diffusion? Explain. For two gases with molecules of approximately the same size, is the ratio of their effusion rates higher than, lower than, or equal to the ratio of their diffusion rates? Explain.

5.73 Consider two 1-L samples of gas: one is H_2 and the other is O_2 . Both are at 1 atm and 25°C . How do the samples compare in terms of (a) mass, (b) density, (c) mean free path, (d) average molecular kinetic energy, (e) average molecular speed, and (f) time for a given fraction of molecules to effuse?

5.74 Three 5-L flasks, fixed with pressure gauges and small valves, each contain 4 g of gas at 273 K. Flask A contains H_2 , flask B contains He, and flask C contains CH_4 . Rank the flask contents in terms of (a) pressure, (b) average kinetic energy of the particles, (c) diffusion rate after the valve is opened, (d) total kinetic energy of the particles, (e) density, and (f) collision frequency.

Skill-Building Exercises (grouped in similar pairs)

5.75 What is the ratio of effusion rates for the lightest gas, H_2 , and the heaviest known gas, UF_6 ?

5.76 What is the ratio of effusion rates for O_2 and Kr?

5.77 The graph below shows the distribution of molecular speeds for argon and helium at the same temperature.

- Does curve 1 or 2 better represent the behavior of argon?
- Which curve represents the gas that effuses more slowly?
- Which curve more closely represents the behavior of fluorine gas? Explain.

5.78 The graph below shows the distribution of molecular speeds for a gas at two different temperatures.

- Does curve 1 or 2 better represent the behavior of the gas at the lower temperature?
- Which curve represents the gas when it has a higher $\overline{E_k}$?
- Which curve is consistent with a higher diffusion rate?

5.79 At a given pressure and temperature, it takes 4.85 min for a 1.5-L sample of He to effuse through a membrane. How long does it take for 1.5 L of F_2 to effuse under the same conditions?

5.80 A sample of an unknown gas effuses in 11.1 min. An equal volume of H_2 in the same apparatus under the same conditions effuses in 2.42 min. What is the molar mass of the unknown gas?

Problems in Context

5.81 White phosphorus melts and then vaporizes at high temperatures. The gas effuses at a rate that is 0.404 times that of neon in

the same apparatus under the same conditions. How many atoms are in a molecule of gaseous white phosphorus?

5.82 Helium (He) is the lightest noble gas component of air, and xenon (Xe) is the heaviest. [For this problem, use $R = 8.314 \text{ J}/(\text{mol} \cdot \text{K})$ and express $\mathcal{M}$ in kg/mol .]

- Find the rms speed of He in winter (0°C) and in summer (30°C).
- Compare the rms speed of He with that of Xe at 30°C .
- Find the average kinetic energy per mole of He and of Xe at 30°C .
- Find the average kinetic energy per molecule of He at 30°C .

5.83 A mixture of gaseous disulfur difluoride, dinitrogen tetrafluoride, and sulfur tetrafluoride is placed in an effusion apparatus.

- Rank the gases in order of increasing effusion rate.
- Find the ratio of effusion rates of disulfur difluoride and dinitrogen tetrafluoride.
- If gas X is added, and it effuses at 0.935 times the rate of sulfur tetrafluoride, find the molar mass of X.

5.84 Naturally occurring uranium ore is 0.7% by mass fissionable ^{235}U and 99.3% by mass nonfissionable ^{238}U . For its use as nuclear reactor fuel, the amount of ^{235}U must be increased relative to the amount of ^{238}U . Uranium ore is treated with fluorine to yield a gaseous mixture of $^{235}\text{UF}_6$ and $^{238}\text{UF}_6$ that is pumped through a series of chambers separated by porous barriers; the lighter $^{235}\text{UF}_6$ molecules ($\mathcal{M} = 349.03 \text{ g}/\text{mol}$) effuse through each barrier faster than molecules of $^{238}\text{UF}_6$ ($\mathcal{M} = 352.04 \text{ g}/\text{mol}$), until the final mixture obtained is 3–5% by mass $^{235}\text{UF}_6$. This process generated 33% of the world's enriched uranium in 2008 but has now been replaced with a less expensive centrifuge process. Calculate the ratio of the effusion rates of $^{235}\text{UF}_6$ to $^{238}\text{UF}_6$.

Real Gases: Deviations from Ideal Behavior

Skill-Building Exercises (grouped in similar pairs)

5.85 Do interparticle attractions cause negative or positive deviations from the PV/RT ratio of an ideal gas? Use Table 5.4 to rank Kr, CO_2 , and N_2 in order of increasing magnitude of these deviations.

5.86 Does particle volume cause negative or positive deviations from the PV/RT ratio of an ideal gas? Use Table 5.4 to rank Cl_2 , H_2 , and O_2 in order of increasing magnitude of these deviations.

5.87 Does N_2 behave more ideally at 1 atm or at 500 atm? Explain.

5.88 Does SF_6 (boiling point = 16°C at 1 atm) behave more ideally at 150°C or at 20°C ? Explain.

Comprehensive Problems

5.89 An “empty” gasoline can with dimensions 15.0 cm by 40.0 cm by 12.5 cm is attached to a vacuum pump and evacuated. If the atmospheric pressure is $14.7 \text{ lb}/\text{in}^2$, what is the total force (in pounds) on the outside of the can?

5.90 Hemoglobin is the protein that transports O_2 through the blood from the lungs to the rest of the body. To do so, each molecule of hemoglobin combines with four molecules of O_2 . If 1.00 g of hemoglobin combines with 1.53 mL of O_2 at 37°C and 743 torr, what is the molar mass of hemoglobin?

5.91 A baker uses sodium hydrogen carbonate (baking soda) as the leavening agent in a banana-nut quickbread. The baking soda decomposes in either of two possible reactions:

Calculate the volume (in mL) of CO_2 that forms at 200°C and 0.975 atm per gram of NaHCO_3 by each of the reaction processes.

5.92 A weather balloon containing 600. L of He is released near the equator at 1.01 atm and 305 K. It rises to a point where conditions are 0.489 atm and 218 K and eventually lands in the northern hemisphere under conditions of 1.01 atm and 250 K. If one-fourth of the helium leaked out during this journey, what is the volume (in L) of the balloon at landing?

5.93 Chlorine is produced from sodium chloride by the electrochemical chlor-alkali process. During the process, the chlorine is collected in a container that is isolated from the other products to prevent unwanted (and explosive) reactions. If a 15.50-L container holds 0.5950 kg of Cl_2 gas at 225°C, calculate:

- (a) P_{IGL}
 (b) P_{VDW} (use $R = 0.08206 \frac{\text{atm}\cdot\text{L}}{\text{mol}\cdot\text{K}}$)

5.94 In a certain experiment, magnesium boride (Mg_3B_2) reacted with acid to form a mixture of four boron hydrides (B_xH_y), three as liquids (labeled I, II, and III) and one as a gas (IV).

- (a) When a 0.1000-g sample of each liquid was transferred to an evacuated 750.0-mL container and volatilized at 70.00°C, sample I had a pressure of 0.05951 atm; sample II, 0.07045 atm; and sample III, 0.05767 atm. What is the molar mass of each liquid?
 (b) Boron was determined to be 85.63% by mass in sample I, 81.10% in II, and 82.98% in III. What is the molecular formula of each sample?
 (c) Sample IV was found to be 78.14% boron. The rate of effusion for this gas was compared to that of sulfur dioxide; under identical conditions, 350.0 mL of sample IV effused in 12.00 min and 250.0 mL of sulfur dioxide effused in 13.04 min. What is the molecular formula of sample IV?

5.95 Three equal volumes of gas mixtures, all at the same T , are depicted below (with gas A red, gas B green, and gas C blue):

- (a) Which sample, if any, has the highest partial pressure of A?
 (b) Which sample, if any, has the lowest partial pressure of B?
 (c) In which sample, if any, do the gas particles have the highest average kinetic energy?

5.96 Will the volume of a gas increase, decrease, or remain unchanged with each of the following sets of changes?

- (a) The pressure is decreased from 2 atm to 1 atm, while the temperature is decreased from 200°C to 100°C.
 (b) The pressure is increased from 1 atm to 3 atm, while the temperature is increased from 100°C to 300°C.
 (c) The pressure is increased from 3 atm to 6 atm, while the temperature is increased from -73°C to 127°C.
 (d) The pressure is increased from 0.2 atm to 0.4 atm, while the temperature is decreased from 300°C to 150°C.

5.97 When air is inhaled, it enters the alveoli of the lungs, and varying amounts of the component gases exchange with dissolved gases in the blood. The resulting alveolar gas mixture is quite different from the atmospheric mixture. The following table presents selected data on the composition and partial pressure of four gases in the atmosphere and in the alveoli:

Gas	Atmosphere (Sea Level)		Alveoli	
	Mole %	Partial Pressure (torr)	Mole %	Partial Pressure (torr)
N_2	78.6	—	—	569
O_2	20.9	—	—	104
CO_2	00.04	—	—	40
H_2O	00.46	—	—	47

If the total pressure of each gas mixture is 1.00 atm, calculate:

- (a) The partial pressure (in torr) of each gas in the atmosphere
 (b) The mole % of each gas in the alveoli
 (c) The number of O_2 molecules in 0.50 L of alveolar air (volume of an average breath of a person at rest) at 37°C

5.98 Radon (Rn) is a radioactive member of Group 18 (noble gases). It is a product of the disintegration of heavier radioactive nuclei found in minute concentrations in many common rocks used for building and construction. In recent years, there has been growing concern about the cancers caused from inhaled residential radon. If 1.0×10^{15} atoms of radium (Ra) produce an average of 1.373×10^4 atoms of Rn per second, how many liters of Rn, measured at STP, are produced per day by 1.0 g of Ra?

5.99 At 1450. mmHg and 286 K, a skin diver exhales a 208-mL bubble of air that is 77% N_2 , 17% O_2 , and 6.0% CO_2 by volume.

- (a) What would the volume (in mL) of the bubble be if it were exhaled at the surface at 1 atm and 298 K?
 (b) How many moles of N_2 are in the bubble?

5.100 Nitrogen dioxide is used industrially to produce nitric acid, but it contributes to acid rain and photochemical smog. What volume (in L) of nitrogen dioxide is formed at 735 torr and 28.2°C by reacting 4.95 cm^3 of copper ($d = 8.95 \text{ g/cm}^3$) with 230.0 mL of nitric acid ($d = 1.42 \text{ g/cm}^3$, 68.0% HNO_3 by mass)?

5.101 In the average adult, the *residual volume* (RV) of the lungs, the volume of air remaining after a forced exhalation, is 1200 mL.

- (a) How many moles of air are present in the RV at 1.0 atm and 37°C?
 (b) How many molecules of gas are present under these conditions?

5.102 In a bromine-producing plant, how many liters of gaseous elemental bromine at 300°C and 0.855 atm are formed by the reaction of 275 g of sodium bromide and 175.6 g of sodium bromate in aqueous acid solution. (Assume that no Br_2 dissolves.)

5.103 In a collision of sufficient force, automobile air bags respond by electrically triggering the explosive decomposition of sodium azide (NaN_3) to its elements. A 50.0-g sample of sodium azide was decomposed, and the nitrogen gas generated was collected over water at 26°C. The total pressure was 745.5 mmHg. How many liters of dry N_2 were generated?

5.104 An anesthetic gas contains 64.81% carbon, 13.60% hydrogen, and 21.59% oxygen, by mass. If 2.00 L of the gas at 25°C and 0.420 atm weighs 2.57 g, what is the molecular formula of the anesthetic?

5.105 Aluminum chloride is easily vaporized above 180°C. The gas escapes through a pinhole 0.122 times as fast as helium at the same conditions of temperature and pressure in the same apparatus. What is the molecular formula of aluminum chloride gas?

5.106 (a) What is the total volume (in L) of gaseous *products*, measured at 350°C and 735 torr, when an automobile engine burns 100. g of C_8H_{18} (a typical component of gasoline)?

(b) For part (a), the source of O_2 is air, which is 78% N_2 , 21% O_2 , and 1.0% Ar by volume. Assuming all the O_2 reacts, but no N_2 or Ar does, what is the total volume (in L) of the engine's gaseous exhaust?

5.107 An atmospheric chemist studying the pollutant SO_2 places a mixture of SO_2 and O_2 in a 2.00-L container at 800. K and 1.90 atm. When the reaction occurs, gaseous SO_3 forms, and the pressure falls to 1.65 atm. How many moles of SO_3 form?

5.108 The thermal decomposition of ethylene occurs during the compound's transit in pipelines and during the formation of polyethylene. The decomposition reaction is

If the decomposition begins at 10°C and 50.0 atm with a gas density of 0.215 g/mL and the temperature increases by 950 K,

(a) What is the final pressure of the confined gas (ignore the volume of graphite and use the van der Waals equation)?

(b) How does the PV/RT value of CH_4 compare to that in Figure 5.24? Explain.

5.109 Ammonium nitrate, a common fertilizer, was used by terrorists in the tragic explosion in Oklahoma City in 1995. How many liters of gas at 307°C and 1.00 atm are formed by the explosive decomposition of 15.0 kg of ammonium nitrate to nitrogen, oxygen, and water vapor?

5.110 An environmental engineer analyzes a sample of air contaminated with sulfur dioxide. To a 500.-mL sample at 700. torr and 38°C, she adds 20.00 mL of 0.01017 M aqueous iodine, which reacts as follows:

Excess I_2 reacts with 11.37 mL of 0.0105 M sodium thiosulfate:

What is the volume % of SO_2 in the air sample?

5.111 Canadian chemists have developed a modern variation of the 1899 Mond process for preparing extremely pure metallic nickel. A sample of impure nickel reacts with carbon monoxide at 50°C to form gaseous nickel carbonyl, $Ni(CO)_4$.

(a) How many grams of nickel can be converted to the carbonyl with 3.55 m³ of CO at 100.7 kPa?

(b) The carbonyl is then decomposed at 21 atm and 155°C to pure (>99.95%) nickel. How many grams of nickel are obtained per cubic meter of the carbonyl?

(c) The released carbon monoxide is cooled and collected for reuse by passing it through water at 35°C. If the barometric pressure is 769 torr, what volume (in m³) of CO is formed per cubic meter of carbonyl?

5.112 Analysis of a newly discovered gaseous silicon-fluorine compound shows that it contains 33.01 mass % silicon. At 27°C, 2.60 g of the compound exerts a pressure of 1.50 atm in a 0.250-L vessel. What is the molecular formula of the compound?

5.113 A gaseous organic compound containing only carbon, hydrogen, and nitrogen is burned in oxygen gas, and the volume of each reactant and product is measured under the same conditions of temperature and pressure. Reaction of four volumes of the compound produces 4 volumes of CO_2 , 2 volumes of N_2 , and 10 volumes of water vapor. (a) How many volumes of O_2 are required? (b) What is the empirical formula of the compound?

5.114 Containers A, B, and C are attached by closed stopcocks of negligible volume.

If each particle shown in the picture represents 10^6 particles,

(a) How many blue particles and black particles are in B after the stopcocks are opened and the system reaches equilibrium?

(b) How many blue particles and black particles are in A after the stopcocks are opened and the system reaches equilibrium?

(c) If the pressure in C, P_C , is 750 torr before the stopcocks are opened, what is P_C afterward?

(d) What is P_B afterward?

5.115 Combustible vapor-air mixtures are flammable over a limited range of concentrations. The minimum volume % of vapor that gives a combustible mixture is called the *lower flammable limit* (LFL). Generally, the LFL is about half the stoichiometric mixture, which is the concentration required for complete combustion of the vapor in air. (a) If oxygen is 20.9 vol % of air, estimate the LFL for *n*-hexane, C_6H_{14} . (b) What volume (in mL) of *n*-hexane ($d = 0.660$ g/cm³) is required to produce a flammable mixture of hexane in 1.000 m³ of air at STP?

5.116 By what factor would a scuba diver's lungs expand if she ascended rapidly to the surface from a depth of 125 ft without inhaling or exhaling? If an expansion factor greater than 1.5 causes lung rupture, how far could she safely ascend from 125 ft without breathing? Assume constant temperature (d of seawater = 1.04 g/mL; d of Hg = 13.5 g/mL).

5.117 When 15.0 g of fluorite (CaF_2) reacts with excess sulfuric acid, hydrogen fluoride gas is collected at 744 torr and 25.5°C. Solid calcium sulfate is the other product. What gas temperature is required to store the gas in an 8.63-L container at 875 torr?

5.118 Dilute aqueous hydrogen peroxide is used as a bleaching agent and for disinfecting surfaces and small cuts. Its concentration is sometimes given as a certain number of "volumes hydrogen peroxide," which refers to the number of volumes of O_2 gas, measured at STP, that a given volume of hydrogen peroxide solution will release when it decomposes to O_2 and liquid H_2O . How many grams of hydrogen peroxide are in 0.100 L of "20 volumes hydrogen peroxide" solution?

5.119 At a height of 300 km above Earth's surface, an astronaut finds that the atmospheric pressure is about 10^{-8} mmHg and the temperature is 500 K. How many molecules of gas are there per milliliter at this altitude?

5.120 (a) What is the rms speed of O_2 at STP? (b) If the mean free path of O_2 molecules at STP is 6.33×10^{-8} m, what is their collision frequency? [Use $R = 8.314$ J/(mol·K) and express $\mathcal{M}$ in kg/mol.]

5.121 Acrylic acid ($CH_2=CHCOOH$) is used to prepare polymers, adhesives, and paints. The first step in making acrylic acid involves the vapor-phase oxidation of propylene ($CH_2=CHCH_3$) to acrolein ($CH_2=CHCHO$). This step is carried out at 330°C and 2.5 atm in a large bundle of tubes around which a heat-transfer agent circulates. The reactants spend an average of 1.8 s in the tubes, which have a void space of 100 ft³. How many pounds of propylene must be added per hour in a mixture whose mole fractions are 0.07 propylene, 0.35 steam, and 0.58 air?

5.122 Standard conditions are based on relevant environmental conditions. If normal average surface temperature and pressure on Venus are 730. K and 90 atm, respectively, what is the standard molar volume of an ideal gas on Venus?

5.123 A barometer tube is 1.00×10^2 cm long and has a cross-sectional area of 1.20 cm^2 . The height of the mercury column is 74.0 cm, and the temperature is 24°C . A small amount of N_2 is introduced into the evacuated space above the mercury, which causes the mercury level to drop to a height of 64.0 cm. How many grams of N_2 were introduced?

5.124 What is the molarity of the cleaning solution formed when 10.0 L of ammonia gas at 33°C and 735 torr dissolves in enough water to give a final volume of 0.750 L?

5.125 The Hawaiian volcano Kilauea emits an average of $1.5 \times 10^3 \text{ m}^3$ of gas each day, when corrected to 298 K and 1.00 atm. The mixture contains gases that contribute to global warming and acid rain, and some are toxic. An atmospheric chemist analyzes a sample and finds the following mole fractions: 0.4896 CO_2 , 0.0146 CO, 0.3710 H_2O , 0.1185 SO_2 , 0.0003 S_2 , 0.0047 H_2 , 0.0008 HCl, and 0.0003 H_2S . How many metric tons (t) of each gas are emitted per year (1 t = 1000 kg)?

5.126 To study a key fuel-cell reaction, a chemical engineer has 20.0-L tanks of H_2 and of O_2 and wants to use up both tanks to form 28.0 mol of water at 23.8°C . (a) Use the ideal gas law to find the pressure needed in each tank. (b) Use the van der Waals equation to find the pressure needed in each tank. (c) Compare the results from the two equations.

5.127 For each of the following, which shows the greater deviation from ideal behavior at the same set of conditions? Explain.

- (a) Argon or xenon (b) Water vapor or neon
(c) Mercury vapor or radon (d) Water vapor or methane

5.128 How many liters of gaseous hydrogen bromide at 29°C and 0.965 atm will a chemist need if she wishes to prepare 3.50 L of 1.20 M hydrobromic acid?

5.129 A mixture consisting of 7.0 g of CO and 10.0 g of SO_2 , two atmospheric pollutants, has a pressure of 0.33 atm when placed in a sealed container. What is the partial pressure of CO?

5.130 Sulfur dioxide is used to make sulfuric acid. One method of producing it is by roasting mineral sulfides, for example,

A production error leads to the sulfide being placed in a 950-L vessel with insufficient oxygen. Initially, the partial pressure of O_2 is 0.64 atm, and the total pressure is 1.05 atm, with the balance due to N_2 . The reaction is run until 85% of the O_2 is consumed, and the vessel is then cooled to its initial temperature. What is the total pressure in the vessel and the partial pressure of each gas in it?

5.131 A mixture of CO_2 and Kr weighs 35.0 g and exerts a pressure of 0.708 atm in its container. Since Kr is expensive, you wish to recover it from the mixture. After the CO_2 is completely removed by absorption with $\text{NaOH}(s)$, the pressure in the container is 0.250 atm. How many grams of CO_2 were originally present? How many grams of Kr can you recover?

5.132 When a car accelerates quickly, the passengers feel a force that presses them back into their seats, but a balloon filled with helium floats forward. Why?

5.133 Gases such as CO are gradually oxidized in the atmosphere, not by O_2 but by the hydroxyl radical, $\cdot\text{OH}$, a species with one fewer electron than a hydroxide ion. At night, the $\cdot\text{OH}$ concentration is nearly zero, but it increases to 2.5×10^{12} molecules/ m^3 in polluted air during the day. At daytime conditions of 1.00 atm and 22°C , what is the partial pressure and mole percent of $\cdot\text{OH}$ in air?

5.134 Aqueous sulfurous acid (H_2SO_3) was made by dissolving 0.200 L of sulfur dioxide gas at 19°C and 745 mmHg in water to yield 500.0 mL of solution. The acid solution required 10.0 mL of sodium hydroxide solution to reach the titration end point. What was the molarity of the sodium hydroxide solution?

5.135 In the 19th century, J. B. A. Dumas devised a method for finding the molar mass of a volatile liquid from the volume, temperature, pressure, and mass of its vapor. He placed a sample of such a liquid in a flask that was closed with a stopper fitted with a narrow tube, immersed the flask in a hot water bath to vaporize the liquid, and then cooled the flask. Find the molar mass of a volatile liquid from the following:

Mass of empty flask = 65.347 g

Mass of flask filled with water at 25°C = 327.4 g

Density of water at 25°C = 0.997 g/mL

Mass of flask plus condensed unknown liquid = 65.739 g

Barometric pressure = 101.2 kPa

Temperature of water bath = 99.8°C

5.136 During World War II, a portable source of hydrogen gas was needed for weather balloons, and solid metal hydrides were the most convenient form. Many metal hydrides react with water to generate the metal hydroxide and hydrogen. Two candidates were lithium hydride and magnesium hydride. What volume (in L) of gas is formed from 1.00 lb of each hydride reacting with excess water at 750. torr and 27°C ?

5.137 The lunar surface reaches 370 K at midday. The atmosphere consists of neon, argon, and helium at a total pressure of only 2×10^{-14} atm. Calculate the rms speed of each component in the lunar atmosphere. [Use $R = 8.314 \text{ J}/(\text{mol} \cdot \text{K})$ and express $\mathcal{M}$ in kg/mol.]

5.138 A person inhales air richer in O_2 and exhales air richer in CO_2 and water vapor. During each hour of sleep, a person exhales a total of about 300 L of this CO_2 -enriched and H_2O -enriched air. (a) If the partial pressures of CO_2 and H_2O in exhaled air are each 30.0 torr at 37.0°C , calculate the mass (g) of CO_2 and of H_2O exhaled in 1 h of sleep. (b) How many grams of body mass does the person lose in 8 h of sleep if all the CO_2 and H_2O exhaled come from the metabolism of glucose?

5.139 Popcorn pops because the horny endosperm, a tough, elastic material, resists gas pressure within the heated kernel until the pressure reaches explosive force. A 0.25-mL kernel has a water content of 1.6% by mass, and the water vapor reaches 170°C and 9.0 atm before the kernel ruptures. Assume that water vapor can occupy 75% of the kernel's volume. (a) What is the mass (in g) of the kernel? (b) How many milliliters would this amount of water vapor occupy at 25°C and 1.00 atm?

5.140 Sulfur dioxide emissions from coal-burning power plants are removed by *flue-gas desulfurization*. The flue gas passes through a scrubber, and a slurry of wet calcium carbonate reacts with it to form carbon dioxide and calcium sulfite. The calcium sulfite then reacts with oxygen to form calcium sulfate, which is

sold as gypsum. (a) If the sulfur dioxide concentration is 1000 times higher than its mole fraction in clean, dry air (2×10^{-10}), how much calcium sulfate (kg) can be made from scrubbing 4 GL of flue gas (1 GL = 1×10^9 L)? A state-of-the-art scrubber removes at least 95% of the sulfur dioxide. (b) If the mole fraction of oxygen in air is 0.209, what volume (L) of air at 1.00 atm and 25°C is needed to react with all the calcium sulfite?

5.141 Many water treatment plants use chlorine gas to kill microorganisms before the water is released for residential use. A plant engineer has to maintain the chlorine pressure in a tank below the 85.0-atm rating and, to be safe, decides to fill the tank to 80.0% of this maximum pressure. (a) How many moles of Cl_2 gas can be kept in an 850.-L tank at 298 K if the engineer uses the ideal gas law in the calculation? (b) What is the tank pressure if the van der Waals equation for this amount of gas is used? (c) Did the engineer fill the tank to the desired pressure?

5.142 At 10.0°C and 102.5 kPa, the density of dry air is 1.26 g/L. What is the average “molar mass” of dry air at these conditions?

5.143 In A, the picture shows a cylinder with 0.1 mol of a gas that behaves ideally. Choose the cylinder (B, C, or D) that correctly represents the volume of the gas after each of the following changes. If none of the cylinders is correct, specify “none.”

- P is doubled at fixed n and T .
- T is reduced from 400 K to 200 K at fixed n and P .
- T is increased from 100°C to 200°C at fixed n and P .
- 0.1 mol of gas is added at fixed P and T .
- 0.1 mol of gas is added and P is doubled at fixed T .

5.144 Ammonia is essential to so many industries that, on a molar basis, it is the most heavily produced substance in the world. Calculate P_{IGL} and P_{VDW} (in atm) of 51.1 g of ammonia in a 3.000-L container at 0°C and 400.°C, the industrial temperature. (See Table 5.4 for the values of the van der Waals constants.)

5.145 A 6.0-L flask contains a mixture of methane (CH_4), argon, and helium at 45°C and 1.75 atm. If the mole fractions of helium and argon are 0.25 and 0.35, respectively, how many molecules of methane are present?

5.146 A large portion of metabolic energy arises from the biological combustion of glucose:

- If this reaction is carried out in an expandable container at 37°C and 780. torr, what volume of CO_2 is produced from 20.0 g of glucose and excess O_2 ?
- If the reaction is carried out at the same conditions with the stoichiometric amount of O_2 , what is the partial pressure of each gas when the reaction is 50% complete (10.0 g of glucose remains)?

5.147 What is the average kinetic energy and rms speed of N_2 molecules at STP? Compare these values with those of H_2 molecules at STP. [Use $R = 8.314 \text{ J}/(\text{mol} \cdot \text{K})$ and express $\mathcal{M}$ in kg/mol .]

5.148 According to government standards, the 8-h threshold limit value is 5000 ppmv for CO_2 and 0.1 ppmv for Br_2 (1 ppmv is 1 part by volume in 10^6 parts by volume). Exposure to either gas for 8 h

above these limits is unsafe. At STP, which of the following would be unsafe for 8 h of exposure?

- Air with a partial pressure of 0.2 torr of Br_2
- Air with a partial pressure of 0.2 torr of CO_2
- 1000 L of air containing 0.0004 g of Br_2 gas
- 1000 L of air containing 2.8×10^{22} molecules of CO_2

5.149 One way to prevent emission of the pollutant NO from industrial plants is by a catalyzed reaction with NH_3 :

(a) If the NO has a partial pressure of 4.5×10^{-5} atm in the flue gas, how many liters of NH_3 are needed per liter of flue gas at 1.00 atm? (b) If the reaction takes place at 1.00 atm and 365°C, how many grams of NH_3 are needed per kiloliter (kL) of flue gas?

5.150 An equimolar mixture of Ne and Xe is accidentally placed in a container that has a tiny leak. After a short while, a very small proportion of the mixture has escaped. What is the mole fraction of Ne in the effusing gas?

5.151 From the relative rates of effusion of $^{235}\text{UF}_6$ and $^{238}\text{UF}_6$, find the number of steps needed to produce a sample of the enriched fuel used in many nuclear reactors, which is 3.0 mole % ^{235}U . The natural abundance of ^{235}U is 0.72%.

5.152 A slight deviation from ideal behavior exists even at normal conditions. If it behaved ideally, 1 mol of CO would occupy 22.414 L and exert 1 atm pressure at 273.15 K. Calculate P_{VDW} for 1.000 mol of CO at 273.15 K. (Use $R = 0.08206 \frac{\text{atm} \cdot \text{L}}{\text{mol} \cdot \text{K}}$.)

5.153 In preparation for a combustion demonstration, a professor fills a balloon with equal molar amounts of H_2 and O_2 , but the demonstration has to be postponed until the next day. During the night, both gases leak through pores in the balloon. If 35% of the H_2 leaks, what is the O_2/H_2 ratio in the balloon the next day?

5.154 Phosphorus trichloride is important in the manufacture of insecticides, fuel additives, and flame retardants. Phosphorus has only one naturally occurring isotope, ^{31}P , whereas chlorine has two, ^{35}Cl (75%) and ^{37}Cl (25%). (a) What different molecular masses (in amu) can be found for PCl_3 ? (b) Which is the most abundant? (c) What is the ratio of the effusion rates of the heaviest and the lightest PCl_3 molecules?

5.155 A truck tire has a volume of 218 L and is filled with air to 35.0 psi at 295 K. After a drive, the air heats up to 318 K. (a) If the tire volume is constant, what is the pressure (in psi)? (b) If the tire volume increases 2.0%, what is the pressure (in psi)? (c) If the tire leaks 1.5 g of air per minute and the temperature is constant, how many minutes will it take for the tire to reach the original pressure of 35.0 psi ($\mathcal{M}$ of air = 28.8 g/mol)?

5.156 Allotropes are different molecular forms of an element, such as dioxygen (O_2) and ozone (O_3). (a) What is the density of each oxygen allotrope at 0°C and 760 torr? (b) Calculate the ratio of densities, $d_{\text{O}_3}/d_{\text{O}_2}$, and explain the significance of this number.

5.157 When gaseous F_2 and solid I_2 are heated to high temperatures, the I_2 sublimates and gaseous iodine heptafluoride forms. If 350. torr of F_2 and 2.50 g of solid I_2 are put into a 2.50-L container at 250. K and the container is heated to 550. K, what is the final pressure (in torr)? What is the partial pressure of I_2 gas?

Who doesn't enjoy toasting marshmallows over a campfire? This delightful activity is a good example of the connection between matter and energy. As the wood burns, a chemical change occurs, during which higher energy compounds in the wood react with oxygen to form lower energy products; energy is released as heat, warming the air and people gathered around the fire. And some of the released heat energy causes another chemical change to occur as the marshmallows are toasted.

This interplay of matter and energy is profoundly important and has an enormous impact on society. On an everyday level, many familiar materials release, absorb, or alter the flow of energy. Fuels such as wood, natural gas, and oil release energy to cook our food, warm our homes, and power our vehicles. Fertilizers help crops convert solar energy into food. Metal wires increase the flow of electrical energy, and polymer fibers in winter clothing slow the flow of thermal energy away from our bodies.

Thermodynamics is the study of energy and its transformations, and three chapters in this text address this central topic. Our focus in this chapter is on **thermochemistry**, the branch of thermodynamics that deals with heat in chemical and physical change. In Chapter 20, we consider *why* reactions occur, and, in Chapter 21, we apply those insights to electrical energy.

IN THIS CHAPTER . . . We see how heat, or thermal energy, flows when matter changes, how to measure the quantity of heat for a given change, and how to determine the direction and magnitude of heat flow for any reaction.

- › We see that energy always flows between a system and its surroundings in the form of heat or work, so the total energy is conserved.
- › We discuss the units of energy and show that the total size of an energy change does not depend on how the change occurs.
- › We identify the heat of a reaction in an open container as a change in enthalpy, which can be negative (exothermic reaction) or positive (endothermic reaction).
- › We describe how a calorimeter measures heat and how the quantity of heat in a reaction is proportional to the amounts of substances.
- › We define standard conditions in order to compare enthalpies of reactions and see how to obtain the change in enthalpy for any reaction.
- › We discuss some current and future energy sources and describe the critical relationship between energy demand and climate change.

6.1 FORMS OF ENERGY AND THEIR INTERCONVERSION

In Chapter 1, we saw that all energy is either potential or kinetic, and that these forms are interconvertible. An object has potential energy by virtue of its position and kinetic energy by virtue of its motion. Let's re-examine these ideas by considering a weight raised above the ground. As the weight is lifted by your muscles or a motor, its potential energy increases; this energy is converted to kinetic energy as the weight

falls (see Figure 1.3). When it hits the ground, some of that kinetic energy appears as *work* done to move the soil and pebbles slightly, and some appears as *heat* when it warms them slightly. Thus, in this situation, *potential energy is converted to kinetic energy, which appears as work and heat.*

Several other forms of energy—solar, electrical, nuclear, and chemical—are examples of potential and kinetic energy on the atomic scale. No matter what the form of energy or the situation, *when energy is transferred from one object to another, it appears as work and/or heat.* In this section, we examine this idea in terms of the release or absorption of energy during a chemical or physical change.

Figure 6.1 A chemical system and its surroundings.

Defining the System and Its Surroundings

In any thermodynamic study, including measuring a change in energy, the experimenter defines the system and the relevant surroundings:

- The **system** is the part of the universe we are focusing on. A typical chemical system is the contents of a flask, usually substances undergoing physical or chemical change (Figure 6.1).
- The **surroundings** are composed of everything else other than the system—the flask itself, the air surrounding the flask, other equipment, and perhaps the rest of the laboratory. In principle, the rest of the universe is the surroundings, but, in practice, we consider only the parts that are relevant to the system: it's not likely that a thunderstorm in central Asia will affect the contents of the flask, but the temperature and pressure of the lab might.

Energy Change (ΔE): Energy Transfer to or from a System

Each particle in a system has potential energy and kinetic energy, and the sum of all these energies is the **internal energy**, E , of the system (some texts use the symbol U). When the reactants in a chemical system change to products, the system's internal energy has changed. This change, ΔE , is the difference between the internal energy *after* the change (E_{final}) and the internal energy *before* the change (E_{initial}), where Δ (Greek *delta*) means “change (or difference) in” calculated as the *final state minus the initial state*. Thus, ΔE is the final quantity of energy of the system **minus** the initial quantity:

$$\Delta E = E_{\text{final}} - E_{\text{initial}} = E_{\text{products}} - E_{\text{reactants}} \quad (6.1)$$

Because the universe consists of only the system and surroundings, *a change in the energy of the system must be accompanied by an **equal and opposite** change in the energy of the surroundings.* In an *energy diagram*, the final and initial states are horizontal lines along a vertical energy axis, with ΔE being the difference in the heights of the lines. A system can change its internal energy in one of two ways:

- By releasing some energy in a transfer *to* the surroundings (Figure 6.2A):

$$E_{\text{final}} < E_{\text{initial}} \quad \text{so} \quad \Delta E = E_{\text{final}} - E_{\text{initial}} < 0$$

- By absorbing some energy in a transfer *from* the surroundings (Figure 6.2B):

$$E_{\text{final}} > E_{\text{initial}} \quad \text{so} \quad \Delta E = E_{\text{final}} - E_{\text{initial}} > 0$$

Thus, ΔE is a *transfer* of energy from system to surroundings, or vice versa.

Figure 6.2 Energy diagrams for the transfer of internal energy (E) between two systems and their surroundings. **A**, When the system releases energy, $\Delta E (E_{\text{final}} - E_{\text{initial}})$ is negative. **B**, When the system absorbs energy, $\Delta E (E_{\text{final}} - E_{\text{initial}})$ is positive. (The vertical yellow arrow always has its tail at the initial state.)

Heat and Work: Two Forms of Energy Transfer

Energy transferred from system to surroundings, or vice versa, appears in two forms:

1. **Heat.** **Heat**, or *thermal energy* (symbolized by q), is the energy transferred as a result of a difference in temperature between the system and the surroundings. For example, energy in the form of heat is transferred *from* hot coffee (system) *to* the mug, your hand, and air (surroundings) because they are at a lower temperature, whereas heat is transferred *from* a hot stove (surroundings) *to* an ice cube (system) because the ice is at a lower temperature.

2. **Work.** All other forms of energy transfer involve some type of **work** (w), the energy transferred when an object is moved by a force. When you (system) kick a football, energy is transferred as work because the force of the kick moves the ball and air (surroundings). When you pump up a ball, energy is transferred as work because the added air (system) exerts a force on the inner wall of the ball (surroundings) and moves it outward.

The total change in a system's internal energy is the sum of the energy transferred as heat and/or as work:

$$\Delta E = q + w \quad (6.2)$$

The values of q and w (and, therefore, of ΔE) can have either a positive or negative sign. We define the sign of the energy change from the **system's** perspective:

- Energy transferred *into* the system is *positive*, because the *system ends up with more* energy.
- Energy transferred *out from* the system is *negative*, because the *system ends up with less* energy.

Innumerable combinations of heat and/or work can change a system's internal energy. In the rest of this subsection, we'll examine the four simplest cases—two that involve only heat and two that involve only work.

Energy Transferred as Heat Only For a system that transfers energy only as heat (q) and does no work ($w = 0$), we have, from Equation 6.2, $\Delta E = q + 0 = q$. There are two ways this transfer can happen:

1. **Heat flowing out from a system to the surroundings** (Figure 6.3A). Suppose hot water is the system and the beaker holding it and the rest of the lab are the surroundings. The water transfers energy as heat outward until the temperature of the water and that of the surroundings are equal. Since heat flows *out* from the system, the final energy of the system is less than the initial energy.

System *releases* energy as heat $\rightarrow q$ is *negative* $\rightarrow E_{\text{final}} < E_{\text{initial}} \rightarrow \Delta E$ is *negative*

Figure 6.3 The two cases where energy is transferred as heat only. **A**, The system releases heat. **B**, The system absorbs heat.

Thermodynamics in the Kitchen

The functioning of two familiar kitchen appliances can clarify the sign of q . The air in a refrigerator (surroundings) has a lower temperature than a newly added piece of food (system), so the food releases energy as heat to the refrigerator air, $q < 0$. The air in a hot oven (surroundings) has a higher temperature than a newly added piece of food (system), so the food absorbs energy as heat from the oven air, $q > 0$.

2. Heat flowing *into* a system *from* the surroundings (Figure 6.3B). If the system consists of ice water, the surroundings transfer energy as heat *into* the system, once again until the ice melts and the temperature of the water and that of the surroundings become equal. In this case, heat flows *in*, so the final energy of the system is higher than its initial energy. ◀

System *absorbs* energy as heat $\rightarrow q$ is *positive* $\rightarrow E_{\text{final}} > E_{\text{initial}} \rightarrow \Delta E$ is *positive*

Energy Transferred as Work Only For a system that transfers energy only as work, $q = 0$; therefore, $\Delta E = 0 + w = w$. There are two ways this transfer can happen:

1. Work done *by* a system *on* the surroundings (Figure 6.4A). Consider the aqueous reaction between zinc and hydrochloric acid to produce hydrogen gas:

The reaction takes place in a nearly evacuated (narrow P_{sys} arrow), insulated container attached to a piston-cylinder assembly. (The container is insulated so that heat does not flow.) We define the system as the reaction mixture, and the container, piston-cylinder, outside air, and so forth as the surroundings. In the initial state, the internal energy is

Figure 6.4 The two cases where energy is transferred as work only. **A**, The system does work on the surroundings. **B**, The system has work done on it by the surroundings.

Table 6.1 | The Sign Conventions* for q , w , and ΔE

q	+	w	=	ΔE
+ (heat <i>absorbed</i>)		+ (work done <i>on</i>)		+ (energy <i>absorbed</i>)
+ (heat <i>absorbed</i>)		– (work done <i>by</i>)		Depends on the <i>sizes</i> of q and w
– (heat <i>released</i>)		+ (work done <i>on</i>)		Depends on the <i>sizes</i> of q and w
– (heat <i>released</i>)		– (work done <i>by</i>)		– (energy <i>released</i>)

*From the perspective of the system.

the energy of the reactants, and, in the final state, it is the energy of the products. Hydrogen gas (shown in *purple*) forms, pushing back the piston as it expands. Thus, energy is transferred as work done *by* the system *on* the surroundings.

System *releases* energy as work done by it $\longrightarrow w$ is *negative* $\longrightarrow$
 $E_{\text{final}} < E_{\text{initial}} \longrightarrow \Delta E$ is *negative*

(The work done here is not very useful because it just pushes back the piston and outside air. But, if the reaction mixture is gasoline and oxygen and the surroundings are an automobile engine, much of the internal energy is transferred as the work done to move the car.)

2. Work done *on* a system *by* the surroundings (Figure 6.4B). Suppose that, after the reaction is over, we increase the pressure of the surroundings (wider P_{surr} arrow) so that the piston moves in, compressing the hydrogen gas into a smaller volume. Energy is transferred as work done *by* the surroundings *on* the system.

System *absorbs* energy as work done on it $\longrightarrow w$ is *positive* $\longrightarrow$
 $E_{\text{final}} > E_{\text{initial}} \longrightarrow \Delta E$ is *positive*

Table 6.1 summarizes the sign conventions for q and w and the effect on the sign of ΔE . Note that the sign for ΔE for a system that transfers energy as *both* heat and work (neither q nor $w = 0$) is determined by the signs and sizes of q and w .

The Law of Energy Conservation

As you've seen, when a system absorbs energy, the surroundings release it, and when a system releases energy, the surroundings absorb it. Energy transferred between system and surroundings can be in the form of heat and/or various types of work—mechanical, electrical, radiant, chemical, and so forth.

Indeed, energy is often converted from one form to another during transfers. For example, when gasoline burns in a car engine, the reaction releases energy that is transferred as heat and work. The heat warms the car parts, passenger compartment, and surrounding air. The work is done when mechanical energy turns the car's wheels and belts. That energy is converted into the electrical energy of the sound system, the radiant energy of the headlights, the chemical energy of the battery, and so forth. The sum of all these forms equals the change in energy between reactants and products as the gasoline burns and the exhaust forms.

Complex biological processes follow the same general pattern. During photosynthesis, green plants use solar energy to convert the chemical energy of the bonds in CO_2 and H_2O into the energy of the bonds in starch and O_2 ; when you digest starch, the energy in its bonds is converted into the muscular (mechanical) energy you need to run a marathon or engage in any activity.

The most important point to realize in these, and all other situations, is that the form of energy may change but energy does not appear or disappear—energy cannot be created or destroyed. Put another way, *energy is conserved: the total energy of the system plus the surroundings remains constant*. This observation can be restated:

- **Law of conservation of energy (first law of thermodynamics):** *the total energy of the universe is constant, or*

$$\Delta E_{\text{universe}} = \Delta E_{\text{system}} + \Delta E_{\text{surroundings}} = 0 \quad (6.3)$$

This law applies, as far as we know, to all systems, from a burning match to continental drift, from the pumping of your heart to the formation of the Solar System.

Figure 6.5 Some quantities of energy. The vertical scale is exponential.

Units of Energy

There are several common energy units:

- The **joule (J)**, the SI unit of energy, is a derived unit composed of three base units:

$$1 \text{ J} = 1 \text{ kg} \cdot \text{m}^2/\text{s}^2$$

Both heat and work are expressed in joules. Let's see why the joule is the unit for work. The work (w) done on a mass is the force (F) times the distance (d) that the mass moves: $w = F \times d$. A *force* changes the velocity of a mass over time; that is, a force *accelerates* a mass. Velocity has units of meters per second (m/s), so acceleration (a) has units of meters per second per second (m/s^2). Force, therefore, has units of mass (m , in kilograms) times acceleration:

$$F = m \times a \quad \text{has units of} \quad \text{kg} \cdot \text{m/s}^2$$

$$\text{Therefore, } w = F \times d \quad \text{has units of} \quad (\text{kg} \cdot \text{m/s}^2) \times \text{m} = \text{kg} \cdot \text{m}^2/\text{s}^2 = \text{J}$$

Since the quantities of energy involved in chemical reactions are usually quite large, chemists use the kilojoule (kJ): $1 \text{ kJ} = 1000 \text{ J}$.

- The **calorie (cal)** is an older unit defined originally as the quantity of energy needed to raise the temperature of 1 g of water by 1°C (specifically, from 14.5°C to 15.5°C). The calorie is now defined in terms of the joule:

$$1 \text{ cal} \equiv 4.184 \text{ J} \quad \text{or} \quad 1 \text{ J} = \frac{1}{4.184} \text{ cal} = 0.2390 \text{ cal}$$

The nutritional Calorie (note the capital C), the unit that measures the energy available from food, is actually a kilocalorie:

$$1 \text{ Cal} = 1000 \text{ cal} = 1 \text{ kcal} = 4184 \text{ J}$$

- The **British thermal unit (Btu)**, a unit you may have seen used for the energy output of appliances, is the quantity of energy required to raise the temperature of 1 lb of water by 1°F :

$$1 \text{ Btu} = 1055 \text{ J}$$

In general, the SI unit (J or kJ) is used in this text. Some interesting quantities of energy are featured in Figure 6.5.

SAMPLE PROBLEM 6.1

Determining the Change in Internal Energy of a System

Problem When gasoline burns in a car engine, the heat released causes the gaseous products CO_2 and H_2O to expand, which pushes the pistons outward. Excess heat is removed by the radiator. If the expanding gases do 451 J of work on the pistons and the system releases 325 J to the surroundings as heat, calculate the change in energy (ΔE) in J, kJ, and kcal.

Plan We define system and surroundings to choose signs for q and w , and then we calculate ΔE with Equation 6.2. The system is the reactants and products, and the surroundings are the pistons, the radiator, and the rest of the car. Heat is released by the system, so q is negative. Work is done by the system to push the pistons outward, so w is also negative. We obtain the answer in J and then convert it to kJ and kcal.

Solution Calculating ΔE (from Equation 6.2) in J:

$$q = -325 \text{ J}$$

$$w = -451 \text{ J}$$

$$\Delta E = q + w = -325 \text{ J} + (-451 \text{ J}) = -776 \text{ J}$$

Converting from J to kJ:

$$\Delta E = -776 \text{ J} \times \frac{1 \text{ kJ}}{1000 \text{ J}} = -0.776 \text{ kJ}$$

Converting from J to kcal:

$$\Delta E = -776 \text{ J} \times \frac{1 \text{ cal}}{4.184 \text{ J}} \times \frac{1 \text{ kcal}}{1000 \text{ cal}} = -0.185 \text{ kcal}$$

Check The answer is reasonable: combustion of gasoline releases energy from the system, so $E_{\text{final}} < E_{\text{initial}}$ and ΔE should be negative.

FOLLOW-UP PROBLEMS

Brief Solutions for **all** Follow-up Problems appear at the end of the chapter.

6.1A A sample of liquid absorbs 13.5 kJ of heat and does 1.8 kJ of work when it vaporizes. Calculate ΔE (in J).

6.1B In a reaction, gaseous reactants form a liquid product. The heat absorbed by the surroundings is 26.0 kcal, and the work done on the system is 15.0 Btu. Calculate ΔE (in kJ).

SOME SIMILAR PROBLEMS 6.9–6.12

State Functions and the Path Independence of the Energy Change

The internal energy (E) of a system is called a **state function**, a property dependent only on the *current* state of the system (its composition, volume, pressure, and temperature), *not* on the path the system takes to reach that state. The energy change of a system can occur through countless combinations of heat (q) and/or work (w). However, because E is a state function, the overall ΔE is the same no matter what the specific combination may be. That is, ΔE *does not depend on how the change takes place, but only on the difference between the final and initial states*.

As an example, let's define a system in its initial state as 1 mol of octane (a component of gasoline) together with enough O_2 to burn it completely. In its final state, the system is the CO_2 and H_2O that form:

Energy is transferred *out* from the system as heat and/or work, so ΔE is negative. Figure 6.6 shows just two of the many ways the change can occur:

- If we burn the octane in an open container (*left*), ΔE is transferred almost completely as heat (with a small quantity of work done to push back the atmosphere).
- If we burn it in a car engine (*right*), a much larger portion ($\sim 30\%$) of ΔE is transferred as work that moves the car, with the rest transferred as heat that warms the car, exhaust gases, and surrounding air.

If we burn the octane in a lawn mower or a motorcycle, ΔE appears as other combinations of work and heat. Thus, q and w are *not* state functions because their values *do* depend on the path the system takes, but ΔE (the *sum* of q and w) *does not*. ▶

As a final example, consider temperature, another state function:

- If you add enough heat to raise the temperature of a sample of water from an initial temperature of 10°C to a final temperature of 60°C :

$$\Delta T = T_{\text{final}} - T_{\text{initial}} = 60^\circ\text{C} - 10^\circ\text{C} = 50^\circ\text{C}.$$

- If instead you add enough heat to raise the temperature of the water from 10°C to 80°C and then you cool the water to 60°C , ΔT is still $60^\circ\text{C} - 10^\circ\text{C} = 50^\circ\text{C}$.

Pressure (P) and volume (V) are some other state functions. Path independence means that *changes in state functions*— ΔE , ΔT , ΔP , and ΔV —*depend only on the initial and final states*.

Your Personal Financial State Function

The *balance* in your checking account is a state function of your personal financial system. You can open a new checking account with a birthday gift of \$50 or with a deposit of a \$100 paycheck and then use your debit card for two \$25 purchases. The two paths to the balance are different, but the balance (current state) is the same.

Figure 6.6 Two different paths for the energy change of a system. Even though q and w for the two paths are different, ΔE is the same.

Figure 6.7 Pressure-volume work. An expanding gas pushing back the atmosphere does *PV* work ($w = -P\Delta V$).

Calculating Pressure-Volume Work (*PV* Work)

The two most important types of chemical work are electrical work, done by moving charged particles (Chapter 21), and a type of mechanical work called **pressure-volume work (*PV* work)**, done when the volume of the system changes in the presence of an external pressure (P). The quantity of *PV* work equals P times the change in volume (ΔV , or $V_{\text{final}} - V_{\text{initial}}$):

$$w = -P\Delta V \quad (6.4)$$

The volume of the system may increase (expand) or decrease (contract).

1. *Work of expansion.* The volume of a gaseous system will increase if the temperature is raised (Charles's law) or if a chemical reaction results in a net increase in the number of moles of gas (Avogadro's law), as in the combustion of propane:

In an open flask (or in a cylinder with a weightless, frictionless piston [Figure 6.7]), a system of an expanding gas does *PV* work *on* the surroundings as it pushes against the atmosphere, so the work has a negative sign. Note that ΔV is positive for a system that is expanding in volume because $V_{\text{final}} > V_{\text{initial}}$. The negative sign in Equation 6.4 is required because *work done by the system means the system lost energy as work*.

2. *Work of contraction.* A gaseous system will decrease in volume if the temperature is lowered or if a reaction results in a net decrease in the number of moles of gas, as in the production of ammonia:

In these situations, *the system has work done on it by the surroundings* as the gas is contracted into a smaller volume by the external pressure. Since $V_{\text{final}} < V_{\text{initial}}$, ΔV is negative, and the work has a positive sign, which means *the system has gained energy as work*.

When we are using Equation 6.4, P is expressed in atmospheres and ΔV in liters, resulting in a unit of $\text{atm}\cdot\text{L}$ for work; we can convert between $\text{atm}\cdot\text{L}$ and joules with the relationship

$$101.3 \text{ J} = 1 \text{ atm}\cdot\text{L}$$

Road Map

SAMPLE PROBLEM 6.2

Calculating Pressure-Volume Work Done by or on a System

Problem A reaction taking place in a container with a piston-cylinder assembly at constant temperature produces a gas, and the volume increases from 125 mL to 652 mL against an external pressure of 988 torr. Calculate the work done (in J; $1 \text{ atm}\cdot\text{L} = 101.3 \text{ J}$).

Plan We are given the external pressure (988 torr) and initial (125 mL) and final volumes (652 mL) and have to find the work done by the gas. We subtract the initial V from the final V to find ΔV and convert it from mL to L. We convert the given P from torr to atm and use Equation 6.4 to calculate w . Then we convert the answer from $\text{atm}\cdot\text{L}$ to J (see the road map).

Solution Calculating ΔV :

$$\Delta V (\text{mL}) = V_{\text{final}} - V_{\text{initial}} = 652 \text{ mL} - 125 \text{ mL} = 527 \text{ mL}$$

Converting ΔV from mL to L:

$$\Delta V (\text{L}) = 527 \text{ mL} \times \frac{1 \text{ L}}{1000 \text{ mL}} = 0.527 \text{ L}$$

Converting P from torr to atm:

$$P (\text{atm}) = 988 \text{ torr} \times \frac{1 \text{ atm}}{760 \text{ torr}} = 1.30 \text{ atm}$$

Calculating w (using Equation 6.4):

$$w (\text{atm}\cdot\text{L}) = -P\Delta V = -(1.30 \text{ atm} \times 0.527 \text{ L}) = -0.685 \text{ atm}\cdot\text{L}$$

Converting from atm·L to J:

$$w (\text{J}) = -0.685 \text{ atm}\cdot\text{L} \times \frac{101.3 \text{ J}}{1 \text{ atm}\cdot\text{L}} = -69.4 \text{ J}$$

Check Since gas is produced, the system expands and does work on the surroundings (energy is released as work), so the negative sign is correct. Rounding shows that the size of the answer is reasonable: $w \approx -1 \text{ atm}\cdot\text{L} \times 0.5 \text{ L} = -0.5 \text{ atm}\cdot\text{L}$.

FOLLOW-UP PROBLEMS

6.2A A gas is compressed at constant temperature from a volume of 5.68 L to a volume of 2.35 L by an external pressure of 732 torr. Calculate the work done (in J).

6.2B A gas-producing reaction occurs in a container with a piston-cylinder assembly under an external pressure of 5.5 atm. At constant temperature, the volume increases from 10.5 L to 16.3 L. Calculate the work done (in J).

SOME SIMILAR PROBLEMS 6.15 and 6.16

Summary of Section 6.1

- Internal energy (E) is transferred as heat (q) when the system and surroundings are at different temperatures or as work (w) when an object is moved by a force.
- Heat absorbed by a system ($q > 0$) or work done on a system ($w > 0$) increases the system's E ; heat released by a system ($q < 0$) or work done by a system ($w < 0$) decreases its E . The change in the internal energy is the sum of the heat and work: $\Delta E = q + w$. Heat and work are measured in joules (J).
- Energy is always conserved: it can change from one form to another and be transferred into or out of a system, but the total quantity of energy in the universe (system *plus* surroundings) is constant.
- The internal energy of a system is a state function and, thus, is independent of how the system attained that energy; therefore, the same overall ΔE can occur through any combination of q and w .
- A system can lose energy by doing work of expansion (increase in volume) or gain energy by having work of contraction done on it (decrease in volume), both of which are forms of pressure-volume (PV) work.

6.2 ENTHALPY: CHANGES AT CONSTANT PRESSURE

Most physical and chemical changes occur at nearly constant atmospheric pressure—a reaction in an open flask, the freezing of a lake, a biochemical process in an organism. In this section, we discuss *enthalpy*, a thermodynamic variable that relates directly to energy changes at constant pressure.

The Meaning of Enthalpy

To determine ΔE , we must measure both heat and work. But, for reactions *at constant pressure*, a thermodynamic quantity called **enthalpy** (H) eliminates the need to measure PV work. The enthalpy of a system is defined as the internal energy *plus* the product of the pressure and volume:

$$H = E + PV$$

The **change in enthalpy** (ΔH) is the change in the system's internal energy *plus* the product of the pressure, which is constant, and the change in volume (ΔV):

$$\Delta H = \Delta E + P\Delta V \quad (6.5)$$

Combining Equations 6.2 ($\Delta E = q + w$) and 6.5 gives

$$\Delta H = \Delta E + P\Delta V = q + w + P\Delta V$$

At constant pressure, we denote q as q_P giving $\Delta H = q_P + w + P\Delta V$. According to Equation 6.4, $w = -P\Delta V$, so $-w$ can be substituted for $P\Delta V$ to give

$$\Delta H = q_P + w + P\Delta V = q_P + w - w$$

which simplifies to

$$\Delta H = \Delta E + P\Delta V = q_P \quad (6.6)$$

Thus, *the change in enthalpy equals the heat absorbed or released at constant pressure*. For most changes occurring at constant pressure, ΔH is more relevant than ΔE and easier to obtain: *to find ΔH , measure q_P only*; work need not be measured. We discuss the laboratory method for doing this in Section 6.3.

Comparing ΔE and ΔH

Knowing the *enthalpy* change of a system tells us a lot about its *energy* change as well. In fact, because many reactions involve little (if any) PV work, most (or all) of the energy change is due to a transfer of heat. Here are three cases:

1. *Reactions that do not involve gases.* Gases do not appear in precipitation reactions, many acid-base reactions, many redox reactions, and so forth. For example,

Because liquids and solids undergo *very* small volume changes, $\Delta V \approx 0$; thus, $P\Delta V \approx 0$; and $\Delta H = \Delta E + P\Delta V \approx \Delta E + 0 \approx \Delta E$.

2. *Reactions in which the amount (mol) of gas does **not** change.* When the total amount of gaseous reactants equals the total amount of gaseous products, the volume is constant, $\Delta V = 0$, so $P\Delta V = 0$ and $\Delta H = \Delta E$. For example,

3. *Reactions in which the amount (mol) of gas **does** change.* In these cases, $P\Delta V \neq 0$. However, q_P is usually *much* larger than $P\Delta V$, so ΔH is still very close to ΔE . For instance, in the combustion of H_2 , 3 mol of gas yields 2 mol of gas:

In this reaction, $\Delta H = -483.6 \text{ kJ}$ and $P\Delta V = -2.5 \text{ kJ}$, so (using Equation 6.5),

$$\Delta H = \Delta E + P\Delta V$$

and

$$\Delta E = \Delta H - P\Delta V = -483.6 \text{ kJ} - (-2.5 \text{ kJ}) = -481.1 \text{ kJ}$$

Since most of ΔE occurs as energy transferred as heat, $\Delta H \approx \Delta E$.

Thus, *for most reactions, ΔH equals, or is very close to, ΔE .*

Exothermic and Endothermic Processes

Because H is a combination of the three state functions E , P , and V , it is also a state function. Therefore, ΔH equals H_{final} *minus* H_{initial} . For a reaction, H_{final} is H_{products} and H_{initial} is $H_{\text{reactants}}$, so the enthalpy change of a reaction is

$$\Delta H = H_{\text{final}} - H_{\text{initial}} = H_{\text{products}} - H_{\text{reactants}}$$

Since H_{products} can be either more or less than $H_{\text{reactants}}$, the *sign* of ΔH indicates whether heat is absorbed or released during the reaction. We determine the sign of ΔH by *imagining the heat as a “reactant” or a “product.”* The two possible types of processes are

1. *Exothermic process: heat as a “product.”* An **exothermic process** releases heat (*exothermic* means “heat out”) and results in a *decrease* in the enthalpy of the system:

$$\text{Exothermic:} \quad H_{\text{products}} < H_{\text{reactants}} \quad \text{so} \quad \Delta H < 0$$

Figure 6.8 Enthalpy diagrams for exothermic and endothermic processes. **A**, The combustion of methane is exothermic: $\Delta H < 0$. **B**, The melting of ice is endothermic: $\Delta H > 0$.

For example, when methane burns in air, heat flows *out of* the system into the surroundings, so we show it as a “product”:

The reactants (1 mol of CH_4 and 2 mol of O_2) release heat during the reaction, so they originally had more enthalpy than the products (1 mol of CO_2 and 2 mol of H_2O):

$$H_{\text{reactants}} > H_{\text{products}} \quad \text{so} \quad \Delta H (H_{\text{products}} - H_{\text{reactants}}) < 0$$

This exothermic change is shown in the **enthalpy diagram** in Figure 6.8A. The ΔH arrow *always* points from reactants to products in this kind of diagram.

2. Endothermic process: heat as a “reactant.” An **endothermic process** *absorbs* heat (*endothermic* means “heat in”) and results in an *increase* in the enthalpy of the system:

$$\text{Endothermic:} \quad H_{\text{products}} > H_{\text{reactants}} \quad \text{so} \quad \Delta H > 0$$

When ice melts, for instance, heat flows *into* the ice from the surroundings, so we show the heat as a “reactant”:

Because heat is absorbed, the enthalpy of the product (water) must be higher than that of the reactant (ice):

$$H_{\text{water}} > H_{\text{ice}} \quad \text{so} \quad \Delta H (H_{\text{water}} - H_{\text{ice}}) > 0$$

This endothermic change is shown in Figure 6.8B. (In general, the value of an enthalpy change is determined with reactants and products at the same temperature.)

SAMPLE PROBLEM 6.3 | Drawing Enthalpy Diagrams and Determining the Sign of ΔH

Problem In each of the following cases, determine the sign of ΔH , state whether the reaction is exothermic or endothermic, and draw an enthalpy diagram:

Plan In each equation, we note whether heat is a “product” (exothermic; $\Delta H < 0$) or a “reactant” (endothermic; $\Delta H > 0$). For exothermic reactions, reactants are above products on the enthalpy diagram; for endothermic reactions, reactants are below products. The ΔH arrow *always* points from reactants to products.

Solution (a) Heat is a product (on the right), so $\Delta H < 0$ and the reaction is **exothermic**. Heat is released during the reaction. See the enthalpy diagram (*top*).

(b) Heat is a reactant (on the left), so $\Delta H > 0$ and the reaction is **endothermic**. Heat is absorbed during the reaction. See the enthalpy diagram (*bottom*).

Check Substances that are on the same side of the equation as the heat have less enthalpy than substances on the other side, so make sure those substances are placed on the lower line of the diagram.

FOLLOW-UP PROBLEMS

6.3A Nitroglycerine decomposes through a violent explosion that releases $5.72 \times 10^3 \text{ kJ}$ of heat per mole:

Is the decomposition of nitroglycerine exothermic or endothermic? Draw an enthalpy diagram for the process.

6.3B Ammonium nitrate is used in some “instant” cold packs because the salt absorbs 25.7 kJ per mole as it dissolves:

Is dissolving ammonium nitrate an exothermic or endothermic process? Draw an enthalpy diagram for the process.

SOME SIMILAR PROBLEMS 6.24–6.29

Summary of Section 6.2

- Enthalpy (H) is a state function, so any change in enthalpy (ΔH) is independent of how the change occurred. At constant P , the value of ΔH equals ΔE plus the PV work, which occurs when the volume of the system changes in the presence of an external pressure.
- ΔH equals q_p , the heat released or absorbed during a chemical or physical change that takes place at constant pressure.
- In most cases, ΔH is equal, or very close, to ΔE .
- A change that releases heat is exothermic ($\Delta H < 0$); a change that absorbs heat is endothermic ($\Delta H > 0$).

6.3 CALORIMETRY: MEASURING THE HEAT OF A CHEMICAL OR PHYSICAL CHANGE

Data about energy content and usage are everywhere, from the caloric value of a slice of pizza to the gas mileage of a car. In this section, we consider the basic ideas used to determine such values.

Specific Heat Capacity

To find the energy change during a process, we measure the quantity of heat released or absorbed by relating it to the change in temperature. You know from everyday experience that, the more you heat an object, the higher its temperature and, the more you cool it, the lower its temperature; in other words, the quantity of heat (q) absorbed or released by an object is proportional to its temperature change:

$$q \propto \Delta T \quad \text{or} \quad q = \text{constant} \times \Delta T \quad \text{or} \quad \frac{q}{\Delta T} = \text{constant}$$

What you might not know is that the temperature change depends on the object. Every object has its own **heat capacity** (C), the quantity of heat required to change its temperature by 1 K. Heat capacity is the proportionality constant in the preceding equation:

$$\text{Heat capacity } (C) = \frac{q}{\Delta T} \quad [\text{in units of J/K}]$$

A related property is **specific heat capacity** (c) (note the lowercase letter), the quantity of heat required to change the temperature of 1 *gram* of a substance or material by 1 K:

$$\text{Specific heat capacity } (c) = \frac{q}{\text{mass} \times \Delta T} \quad [\text{in units of J/g}\cdot\text{K}]$$

If we know c for the object being heated (or cooled), we can measure the mass and the temperature change and calculate the heat absorbed (or released):

$$q = c \times \text{mass} \times \Delta T \quad (6.7)$$

According to Equation 6.7,

- When an object absorbs heat and gets hotter, T_{final} is greater than T_{initial} , ΔT ($T_{\text{final}} - T_{\text{initial}}$) is positive, and so q is positive (an endothermic process).
- When an object releases heat and gets cooler, T_{final} is lower than T_{initial} , ΔT is negative, and so q is negative (an exothermic process).

Table 6.2 lists the specific heat capacities of some representative substances and materials. Notice that metals have relatively low values of c and water has a very

Table 6.2

Specific Heat Capacities (c) of Some Elements, Compounds, and Materials

Substance	c (J/g·K)*
Elements	
Aluminum, Al	0.897
Graphite, C	0.709
Iron, Fe	0.449
Copper, Cu	0.385
Gold, Au	0.129
Compounds	
Water, $\text{H}_2\text{O}(l)$	4.18
Ethyl alcohol, $\text{C}_2\text{H}_5\text{OH}(l)$	2.438
Ethylene glycol, $(\text{CH}_2\text{OH})_2(l)$	2.394
Carbon tetrachloride, $\text{CCl}_4(l)$	0.85
Materials	
Wood	1.76
Cement	0.88
Glass	0.84
Granite	0.79
Steel	0.45

*At 298 K (25°C).

high value: for instance, it takes over 30 times as much energy to increase the temperature of a gram of water by 1 K as it does a gram of gold!

Closely related to the specific heat capacity (but reserved for substances) is the **molar heat capacity** (C_m), the quantity of heat required to change the temperature of 1 *mole* of a substance by 1 K:

$$\text{Molar heat capacity } (C_m) = \frac{q}{\text{amount (mol)} \times \Delta T} \quad [\text{in units of J/mol}\cdot\text{K}]$$

To find C_m of liquid H_2O , we multiply c of liquid H_2O ($4.18 \text{ J/g}\cdot\text{K}$) by the molar mass of H_2O (18.02 g/mol):

$$C_m \text{ of } \text{H}_2\text{O}(l) = 4.18 \frac{\text{J}}{\text{g}\cdot\text{K}} \times \frac{18.02 \text{ g}}{1 \text{ mol}} = 75.3 \frac{\text{J}}{\text{mol}\cdot\text{K}}$$

Liquid water has a *very* high specific heat capacity ($\sim 4.2 \text{ J/g}\cdot\text{K}$), about six times that of rock ($\sim 0.7 \text{ J/g}\cdot\text{K}$). If Earth had no oceans (*see photo*), it would take one-sixth as much energy for the Sun to heat the rocky surface, and the surface would give off six times as much heat after sundown. Days would be scorching and nights frigid. Water's high specific heat capacity means that large bodies of water require a lot more heat for a given increase in temperature than landmasses do. Earth's oceans help regulate its weather and climate.

Earth without oceans.

SAMPLE PROBLEM 6.4

Relating Quantity of Heat and Temperature Change

Problem (a) A layer of copper welded to the bottom of a skillet weighs 125 g. How much heat is needed to raise the temperature of the copper layer from 25°C to 90°C ? (b) How much heat is needed to raise the temperature of the same mass (125 g) of water from 25°C to 90°C ? The specific heat capacity (c) values of Cu and H_2O are given in Table 6.2. (c) Explain the reason for the difference in the answers obtained for the copper versus water.

Plan We know the mass (125 g) and c of Cu ($0.385 \text{ J/g}\cdot\text{K}$) and of water ($4.18 \text{ J/g}\cdot\text{K}$) and can find ΔT in $^\circ\text{C}$, which equals ΔT in K. We then use Equation 6.7 to calculate the heat required for the changes.

Solution Calculating ΔT for Cu and water:

$$\Delta T = T_{\text{final}} - T_{\text{initial}} = 90.^\circ\text{C} - 25^\circ\text{C} = 65^\circ\text{C} = 65 \text{ K}$$

(a) Calculating q for Cu:

$$q = c \times \text{mass (g)} \times \Delta T = 0.385 \text{ J/g}\cdot\text{K} \times 125 \text{ g} \times 65 \text{ K} = 3.13 \times 10^3 \text{ J}$$

(b) Calculating q for water:

$$q = c \times \text{mass (g)} \times \Delta T = 4.18 \text{ J/g}\cdot\text{K} \times 125 \text{ g} \times 65 \text{ K} = 3.40 \times 10^4 \text{ J}$$

(c) The heat required to raise the temperature of the water is 10.9 times the amount needed to heat an equal mass of copper: $3.40 \times 10^4 / 3.13 \times 10^3 = 10.9$; the specific heat capacity of water is 10.9 times greater than the specific heat capacity of copper: $4.18 / 0.385 = 10.9$. The higher specific heat capacity of water means that more heat is required to change the temperature of the water.

Check Heat is absorbed by the copper bottom (system) and the water, so q is positive. Rounding shows the arithmetic is reasonable:

$$q_{\text{Cu}} \approx 0.4 \text{ J/g}\cdot\text{K} \times 100 \text{ g} \times 60 \text{ K} = 2.4 \times 10^3 \text{ J.}$$

$$q_{\text{H}_2\text{O}} \approx 4 \text{ J/g}\cdot\text{K} \times 100 \text{ g} \times 60 \text{ K} = 2.4 \times 10^4 \text{ J.}$$

Comment Remember that the Kelvin temperature scale uses the same size degree as the Celsius scale; for this reason, ΔT has the same value regardless of which of the two temperature scales is used to express T_{initial} and T_{final} . In this problem, $90.^\circ\text{C} = 363 \text{ K}$, $25^\circ\text{C} = 298 \text{ K}$, and $\Delta T = 363 \text{ K} - 298 \text{ K} = 65 \text{ K}$, as shown above.

FOLLOW-UP PROBLEMS

6.4A Before baking a pie, you line the bottom of an oven with a 7.65-g piece of aluminum foil and then raise the oven temperature from 18°C to 375°C. Use Table 6.2 to find the heat (in J) absorbed by the foil.

6.4B The ethylene glycol ($d = 1.11 \text{ g/mL}$; also see Table 6.2) in a car radiator cools from 37.0°C to 25.0°C by releasing 177 kJ of heat. What volume of ethylene glycol is in the radiator?

SOME SIMILAR PROBLEMS 6.37–6.40

The Two Major Types of Calorimetry

How do we know the heat of an acid-base reaction or the Calories in a teaspoon of sugar? In the lab, we construct “surroundings” that retain the heat as reactants change to products, then note the temperature change. These “surroundings” take the form of a **calorimeter**, a device used to measure the heat released (or absorbed) by a physical or chemical process. Let’s look at two types of calorimeter—one designed to measure the heat at constant pressure and the other at constant volume.

Constant-Pressure Calorimetry For processes that take place at constant pressure, the heat transferred (q_p) is often measured in a *coffee-cup calorimeter* (Figure 6.9). This simple apparatus can be used to find the heat of an aqueous reaction, the heat accompanying the dissolving of a salt, or even the specific heat capacity of a solid that does not react with or dissolve in water.

Let’s examine the third application first. The solid (the system) is weighed, heated to some known temperature, and added to a known mass and temperature of water (surroundings) in the calorimeter. After stirring, the final water temperature is measured, which is also the final temperature of the solid. Assuming no heat escapes the insulated calorimeter, the heat *released* by the system ($-q_{\text{sys}}$ or $-q_{\text{solid}}$) as it cools is equal in magnitude but opposite in sign to the heat *absorbed* by the surroundings ($+q_{\text{surr}}$ or $+q_{\text{H}_2\text{O}}$) as they warm:

$$-q_{\text{solid}} = q_{\text{H}_2\text{O}}$$

Substituting from Equation 6.7 on each side of this equation gives

$$-(c_{\text{solid}} \times \text{mass}_{\text{solid}} \times \Delta T_{\text{solid}}) = c_{\text{H}_2\text{O}} \times \text{mass}_{\text{H}_2\text{O}} \times \Delta T_{\text{H}_2\text{O}}$$

All the quantities are known or measured except c_{solid} :

$$c_{\text{solid}} = -\frac{c_{\text{H}_2\text{O}} \times \text{mass}_{\text{H}_2\text{O}} \times \Delta T_{\text{H}_2\text{O}}}{\text{mass}_{\text{solid}} \times \Delta T_{\text{solid}}}$$

SAMPLE PROBLEM 6.5

Determining the Specific Heat Capacity of a Solid

Problem You heat 22.05 g of a solid in a test tube to 100.00°C and then add the solid to 50.00 g of water in a coffee-cup calorimeter. The water temperature changes from 25.10°C to 28.49°C. Find the specific heat capacity of the solid.

Plan We are given the masses of the solid (22.05 g) and of H_2O (50.00 g), and we can find the temperature changes of the water and of the solid by subtracting the given values, always using $T_{\text{final}} - T_{\text{initial}}$. Using Equation 6.7, we set the heat released by the solid ($-q_{\text{solid}}$) equal to the heat absorbed by the water ($q_{\text{H}_2\text{O}}$). The specific heat of water is known, and we solve for c_{solid} .

Solution Finding ΔT_{solid} and $\Delta T_{\text{H}_2\text{O}}$:

$$T_{\text{initial}}(\text{solid}) = 100.00^\circ\text{C}; \quad T_{\text{initial}}(\text{H}_2\text{O}) = 25.10^\circ\text{C}; \quad T_{\text{final}}(\text{solid and H}_2\text{O}) = 28.49^\circ\text{C}$$

$$\Delta T_{\text{H}_2\text{O}} = T_{\text{final}} - T_{\text{initial}} = 28.49^\circ\text{C} - 25.10^\circ\text{C} = 3.39^\circ\text{C} = 3.39 \text{ K}$$

$$\Delta T_{\text{solid}} = T_{\text{final}} - T_{\text{initial}} = 28.49^\circ\text{C} - 100.00^\circ\text{C} = -71.51^\circ\text{C} = -71.51 \text{ K}$$

The negative sign on ΔT_{solid} indicates that the solid has cooled.

Figure 6.9 Coffee-cup calorimeter. This device measures the heat transferred at constant pressure (q_p).

Solving for c_{solid} :

$$c_{\text{solid}} = -\frac{c_{\text{H}_2\text{O}} \times \text{mass}_{\text{H}_2\text{O}} \times \Delta T_{\text{H}_2\text{O}}}{\text{mass}_{\text{solid}} \times \Delta T_{\text{solid}}} = -\frac{4.18 \text{ J/g}\cdot\text{K} \times 50.00 \text{ g} \times 3.39 \text{ K}}{22.05 \text{ g} \times (-71.51 \text{ K})} = 0.449 \text{ J/g}\cdot\text{K}$$

Check Rounding gives $-4 \text{ J/g}\cdot\text{K} \times 50 \text{ g} \times 3 \text{ K} / [20 \text{ g} \times (-70^\circ\text{C})] = 0.4 \text{ J/g}\cdot\text{K}$, so the answer seems correct.

Comment Notice that the water had a temperature change of 3.39 K, whereas the solid had a significantly larger temperature change of 71.51 K. The fact that the mass of solid is half that of water plays a role in the difference in ΔT values, but the more important factor is the fact that water has a specific heat capacity that is nine times greater than the solid.

FOLLOW-UP PROBLEMS

6.5A A 12.18-g sample of a shiny, orange-brown metal is heated to 65.00°C and then added to 25.00 g of water in a coffee-cup calorimeter. The water temperature changes from 25.55°C to 27.25°C . What is the unknown metal (see Table 6.2)?

6.5B A 33.2-g titanium bicycle part is added to 75.0 g of water in a coffee-cup calorimeter at 50.00°C , and the temperature drops to 49.30°C . What was the initial temperature (in $^\circ\text{C}$) of the metal part (c of titanium is $0.228 \text{ J/g}\cdot\text{K}$)?

SOME SIMILAR PROBLEMS 6.41–6.46

In the next sample problem, we will look at the process of calculating ΔH for a reaction that occurs in aqueous solution in a coffee-cup calorimeter. It is important to note that

- An exothermic reaction releases heat that is absorbed by the solution and the temperature of the solution increases.
- An endothermic reaction absorbs heat and the temperature of the solution decreases.
- $q_{\text{soln}} = -q_{\text{rxn}}$
- Since the reaction takes place at constant pressure, q_{rxn} is equal to ΔH for the reaction.

SAMPLE PROBLEM 6.6

Determining the Enthalpy Change of an Aqueous Reaction

Problem You place 50.0 mL of 0.500 M NaOH in a coffee-cup calorimeter at 25.00°C and add 25.0 mL of 0.500 M HCl, also at 25.00°C . After stirring, the final temperature is 27.21°C . [Assume that the total volume is the sum of the individual volumes and that the final solution has the same density (1.00 g/mL) and specific heat capacity (see Table 6.2) as water.] (a) Calculate q_{rxn} (in J). (b) Calculate the change in enthalpy, ΔH , of the reaction in kJ/mol of H_2O formed.

(a) Calculate q_{rxn}

Plan The reaction is the system and the solution is the surroundings; as the reaction takes place, heat flows into the solution (the temperature of the solution increases). Thus, the reaction is exothermic. Since we have the volume and temperature change of the solution, we find q_{soln} first and then determine q_{rxn} . To find q_{soln} , we use Equation 6.7, so we need the mass of solution, the change in temperature, and the specific heat capacity. We know the solutions' volumes (25.0 mL and 50.0 mL), so we find their masses with the given density (1.00 g/mL). Then, to find q_{soln} , we multiply the total mass by the given c ($4.18 \text{ J/g}\cdot\text{K}$) and the change in T , which we find from $T_{\text{final}} - T_{\text{initial}}$. To find q_{rxn} , we recognize that the heat *absorbed* by the solution ($q_{\text{soln}} > 0$) was *released* by the reaction ($q_{\text{rxn}} < 0$) (see the road map).

Solution Finding $\text{mass}_{\text{soln}}$ and ΔT_{soln} :

$$\text{Total mass (g) of solution} = (25.0 \text{ mL} + 50.0 \text{ mL}) \times 1.00 \text{ g/mL} = 75.0 \text{ g}$$

$$\Delta T = 27.21^\circ\text{C} - 25.00^\circ\text{C} = 2.21^\circ\text{C} = 2.21 \text{ K}$$

Road Map (a)

Road Map (b)

Finding q_{soln} :

$$q_{\text{soln}} = c_{\text{soln}} \times \text{mass}_{\text{soln}} \times \Delta T_{\text{soln}} = (4.18 \text{ J/g}\cdot\text{K})(75.0 \text{ g})(2.21 \text{ K}) = 693 \text{ J}$$

Finding q_{rxn} :

Heat *absorbed* by the solution ($q_{\text{soln}} > 0$) was *released* by the reaction ($q_{\text{rxn}} < 0$); that is,

$$q_{\text{soln}} = -q_{\text{rxn}} = 693 \text{ J} \quad \text{so} \quad q_{\text{rxn}} = -693 \text{ J}$$

Check The value of q_{soln} is positive since heat flowed into the solution; the value of q_{rxn} is negative because the reaction releases heat to the solution. Rounding to check the size of q_{rxn} gives $-(4 \text{ J/g}\cdot\text{K} \times 75 \text{ g} \times 2 \text{ K}) = -600 \text{ J}$, which is close to the answer.

(b) Calculate the change in enthalpy (ΔH)

Plan The heat of reaction (q_{rxn}) equals ΔH . Dividing q_{rxn} by the amount (mol) of water formed in the reaction gives ΔH in kJ per mole of water formed. To calculate the amount (mol) of water formed, we write the balanced equation for the acid-base reaction and use the volumes and the concentrations (0.500 *M*) to find amount (mol) of each reactant (H^+ and OH^-). Since the amounts of two reactants are given, we determine which is limiting, that is, which produces less H_2O (see the road map).

Solution Writing the balanced equation:

Finding amounts (mol) of reactants:

$$\text{Amount (mol) of HCl} = 0.500 \text{ mol HCl/L} \times 0.0250 \text{ L} = 0.0125 \text{ mol HCl}$$

$$\text{Amount (mol) of NaOH} = 0.500 \text{ mol NaOH/L} \times 0.0500 \text{ L} = 0.0250 \text{ mol NaOH}$$

Finding the amount (mol) of product: all the coefficients in the equation are 1, which means that the amount (mol) of reactant yields that amount of product. Therefore, HCl is limiting because it yields less product: 0.0125 mol of H_2O .

Finding ΔH :

$$\Delta H (\text{kJ/mol}) = \frac{q_{\text{rxn}}}{\text{mol H}_2\text{O}} \times \frac{1 \text{ kJ}}{1000 \text{ J}} = \frac{-693 \text{ J}}{0.0125 \text{ mol H}_2\text{O}} \times \frac{1 \text{ kJ}}{1000 \text{ J}} = -55.4 \text{ kJ/mol H}_2\text{O}$$

Check We check for the limiting reactant: the volume of H^+ is half the volume of OH^- , but they have the same concentration and a 1/1 stoichiometric ratio. Therefore, the amount (mol) of H^+ determines the amount of product. Rounding to find ΔH gives $-700 \text{ J}/0.012 \text{ mol} = -6 \times 10^4 \text{ J/mol}$, or -60 kJ/mol , so the answer seems correct.

FOLLOW-UP PROBLEMS

6.6A When 50.0 mL of 0.500 *M* HCl and 50.0 mL of 0.500 *M* $\text{Ba}(\text{OH})_2$, both at 21.90°C, react in a coffee-cup calorimeter, the temperature of the mixture rises to 25.21°C.

(a) Write balanced molecular and net ionic equations for the reaction.

(b) Calculate ΔH of the reaction in kJ/mol of H_2O formed. (Assume that the final volume is the sum of the volumes being mixed and that the final solution has $d = 1.00 \text{ g/mL}$ and $c = 4.18 \text{ J/g}\cdot\text{K}$.)

6.6B When 3.15 g of NH_4NO_3 is dissolved in 75.0 g of water in a coffee-cup calorimeter, the temperature decreases from 24.60°C to 21.50°C. Calculate ΔH in kJ/mol of NH_4NO_3 for the solution process. (Assume that the final solution has the specific heat capacity of water.)

SOME SIMILAR PROBLEMS 6.47 and 6.48

Constant-Volume Calorimetry Constant-volume calorimetry is carried out in a *bomb calorimeter*, a device commonly used to measure the heat of combustion reactions, usually involving fuels or foods. With a coffee-cup calorimeter, we simply assume that all the heat is absorbed by the water, but, in reality, some is

Figure 6.10 A bomb calorimeter. This device measures the heat released at constant volume (q_V).

absorbed by the stirrer, thermometer, cups, and so forth. With the much more precise bomb calorimeter, the *heat capacity of the entire calorimeter* is known (or can be determined).

Figure 6.10 depicts the preweighed combustible sample in a metal-walled chamber (the bomb), which is filled with oxygen gas and immersed in an insulated water bath fitted with motorized stirrer and thermometer. A heating coil connected to an electrical source ignites the sample, and the heat released raises the temperature of the bomb, water, and other calorimeter parts.

Recall from Equation 6.7 that the heat absorbed by the calorimeter can be calculated using the relationship

$$q_{\text{calorimeter}} = c_{\text{calorimeter}} \times \text{mass}_{\text{calorimeter}} \times \Delta T_{\text{calorimeter}}$$

Multiplying $c_{\text{calorimeter}} \times \text{mass}_{\text{calorimeter}}$ gives the heat capacity of the entire calorimeter, $C_{\text{calorimeter}}$, in units of J/K or kJ/K. Thus, Equation 6.7 can be simplified to

$$q_{\text{calorimeter}} = C_{\text{calorimeter}} \times \Delta T_{\text{calorimeter}} \quad (6.8)$$

Because we know the heat capacity of the entire calorimeter, we can use the measured ΔT of the calorimeter to calculate the heat *absorbed* by the calorimeter; changing the sign gives the heat *released* during the combustion of the sample:

$$-q_{\text{rxn}} = q_{\text{calorimeter}}$$

Note that the steel bomb is tightly sealed, not open to the atmosphere as is the coffee cup, so the pressure is *not* constant. And the volume of the bomb is fixed, so $\Delta V = 0$, and $P\Delta V = 0$. Thus, the energy change measured is the *heat released at constant volume* (q_V), which equals ΔE , not ΔH :

$$\Delta E = q + w = q_V + 0 = q_V$$

Recall from Section 6.2, however, that, even though the number of moles of gas may change, $P\Delta V$ is usually *much* less than ΔE , so ΔH is very close to ΔE . For example, ΔH is only 0.5% larger than ΔE for the combustion of H_2 and only 0.2% smaller than ΔE for the combustion of octane.

Road Map

Student Hot Spot

Student data indicate you may struggle with constant-volume calorimetry calculations. Access the eBook to view an additional Learning Resource video on this topic.

SAMPLE PROBLEM 6.7

Calculating the Heat of a Combustion Reaction

Problem Acetylene torches produce such high temperatures that they are often used to weld and cut metal. When 2.50 g of acetylene (C_2H_2) is burned in a bomb calorimeter with a heat capacity of 10.85 kJ/K, the temperature increases from 23.488°C to 34.988°C. What is ΔE (in kJ/mol) for this combustion reaction?

Plan To find the heat released during the combustion of 2.50 g of acetylene, we find ΔT , multiply it by the given heat capacity of the calorimeter (10.85 kJ/K), and change the sign, since $-q_{\text{rxn}} = q_{\text{calorimeter}}$. We use the molar mass of acetylene to calculate ΔE , the heat released by 1 mole of acetylene (see the road map).

Solution Finding ΔT :

$$\Delta T = T_{\text{final}} - T_{\text{initial}} = 34.988^\circ\text{C} - 23.488^\circ\text{C} = 11.500^\circ\text{C} = 11.500 \text{ K}$$

Calculating the heat absorbed by the calorimeter:

$$q_{\text{calorimeter}} = C_{\text{calorimeter}} \times \Delta T = 10.85 \text{ kJ/K} \times 11.500 \text{ K} = 124.8 \text{ kJ}$$

Therefore, $q_{\text{rxn}} = -124.8 \text{ kJ}$ for 2.50 g of acetylene.

$$\Delta E = \frac{-124.8 \text{ kJ}}{2.50 \text{ g C}_2\text{H}_2} \times \frac{26.04 \text{ g C}_2\text{H}_2}{1 \text{ mol C}_2\text{H}_2} = -1.30 \times 10^3 \text{ kJ/mol C}_2\text{H}_2$$

Check A quick math check shows that the answer is reasonable: $11 \text{ kJ/K} \times 12 \text{ K} = 132 \text{ kJ}$ for combustion of a 2.50-g sample. Since 1 mol of C_2H_2 has about 10 times that mass, ΔE should be $10 \times -132 \text{ kJ} = -1320 \text{ kJ}$.

FOLLOW-UP PROBLEMS

6.7A A chemist burns 0.8650 g of graphite (a form of carbon) in a bomb calorimeter, and CO_2 forms. If 393.5 kJ of heat is released per mole of graphite and ΔT is 3.116 K, what is the heat capacity of the bomb calorimeter?

6.7B A manufacturer claims that its new dietetic dessert has “fewer than 10 Calories per serving.” To test the claim, a chemist at the Department of Consumer Affairs places one serving in a bomb calorimeter and burns it in O_2 . The initial temperature is 21.862°C, and the temperature rises to 26.799°C. If the heat capacity of the calorimeter is 8.151 kJ/K, is the manufacturer’s claim correct?

SOME SIMILAR PROBLEMS 6.49, 6.50, 6.51, and 6.53

Summary of Section 6.3

- ▶ We calculate ΔH of a process by measuring the energy transferred as heat at constant pressure (q_p). To do this, we determine ΔT and multiply it by the substance’s mass and by its specific heat capacity (c), which is the quantity of energy needed to raise the temperature of 1 g of the substance by 1 K.
- ▶ Calorimeters measure the heat released (or absorbed) during a process either at constant pressure (coffee cup; $q_p = \Delta H$) or at constant volume (bomb; $q_v = \Delta E$).

6.4

STOICHIOMETRY OF THERMOCHEMICAL EQUATIONS

A **thermochemical equation** is a balanced equation that includes the enthalpy change of the reaction (ΔH). Keep in mind that a given ΔH refers only to the *amounts (mol) of substances and their states of matter in that equation*. The enthalpy change of any process has two aspects:

- **Sign.** The sign of ΔH depends on whether the reaction is exothermic (−) or endothermic (+). A forward reaction has the *opposite* sign of the reverse reaction. Decomposition of 2 mol of water to its elements (endothermic):

Figure 6.11 The relationship between amount (mol) of substance and the energy (kJ) transferred as heat during a reaction.

Formation of 2 mol of water from its elements (exothermic):

- **Magnitude.** The magnitude of ΔH is *proportional to the amount of substance*.

Formation of 1 mol of water from its elements (half the preceding amount):

Two key points to understand about thermochemical equations are

1. **Balancing coefficients.** When necessary, we use fractional coefficients to balance an equation, because we are specifying the magnitude of ΔH for a *particular amount*, often 1 mol, of a substance, for example, gaseous SO_2 :

2. **Thermochemical equivalence.** For a *particular reaction*, a certain amount of substance is thermochemically equivalent to a certain quantity of energy. Just as we use stoichiometrically equivalent molar ratios to find amounts of substances, we use thermochemically equivalent quantities to find the ΔH of a reaction for a given amount of substance. Some examples from the previous two reactions are

296.8 kJ is thermochemically equivalent to $\frac{1}{8}$ mol of $\text{S}_8(\text{s})$

286 kJ is thermochemically equivalent to $\frac{1}{2}$ mol of $\text{O}_2(\text{g})$

286 kJ is thermochemically equivalent to 1 mol of $\text{H}_2\text{O}(\text{l})$

Also, just as we use molar mass (in g/mol) to convert an amount (mol) of a substance to mass (g), we use the ΔH (in kJ/mol) to convert an amount (mol) of a substance to an equivalent quantity of heat (in kJ). Figure 6.11 shows this new relationship, and Sample Problem 6.8 applies it.

SAMPLE PROBLEM 6.8

Using a Thermochemical Equation to Convert Between Amount of Substance and Heat

Problem The major source of aluminum in the world is bauxite (mostly aluminum oxide). Its thermal decomposition can be written as

(a) If aluminum is produced this way (see Comment), how many grams of aluminum can form when 1.000×10^3 kJ of heat is absorbed? (b) What amount of heat is absorbed when 46.5 g of Al_2O_3 reacts?

Plan (a) From the balanced equation and the enthalpy change, we see that 1676 kJ of heat is thermochemically equivalent to 2 mol of Al. With this equivalent quantity, we convert the given number of kJ to amount (mol) formed and then convert amount to mass in g. (b) The thermochemical equation tells us that 1676 kJ of heat is equivalent to 1 mol of Al_2O_3 . We convert mass in g to mol of Al_2O_3 and use the equivalent quantity to convert from mol of reactant to kJ of heat absorbed. (see the road map).

Solution (a) Combining steps to convert from heat transferred to mass of Al:

$$\text{Mass (g) of Al} = (1.000 \times 10^3 \text{ kJ}) \times \frac{2 \text{ mol Al}}{1676 \text{ kJ}} \times \frac{26.98 \text{ g Al}}{1 \text{ mol Al}} = 32.20 \text{ g Al}$$

(b) Combining steps to convert from mass of Al_2O_3 to heat absorbed:

$$\text{Heat (kJ) absorbed} = 46.5 \text{ g Al}_2\text{O}_3 \times \frac{1 \text{ mol Al}_2\text{O}_3}{101.96 \text{ g Al}_2\text{O}_3} \times \frac{1676 \text{ kJ}}{1 \text{ mol Al}_2\text{O}_3} = 764 \text{ kJ}$$

Check (a) The mass of aluminum seems correct: ~ 1700 kJ forms about 2 mol of Al (54 g), so 1000 kJ should form a bit more than half that amount (27 g). (b) 1 mol of

Road Map (a)

Road Map (b)

Al_2O_3 (~100 g) results in the absorption of ~1700 kJ, so a little less than half that mass of Al_2O_3 (46.5 g) should mean that a little less than half of 1700 kJ (850 kJ) should be absorbed.

Comment In practice, aluminum is not obtained by heating bauxite but by supplying electrical energy (as you'll see in Chapter 22). Because H is a state function, however, the total energy required for the change is the same no matter how it occurs.

FOLLOW-UP PROBLEMS

6.8A More than 175 million metric tons of ammonia is produced from its elements each year for use in fertilizers, explosives, and plastics:

What mass of hydrogen has reacted if 142 kJ of heat is released during the reaction?

6.8B In the searing temperatures reached in a lightning bolt, nitrogen and oxygen form nitrogen monoxide, NO. If 182.6 kJ of heat is absorbed per mole of N_2 reacting, how much heat is absorbed when 3.50 metric tons (t; 1 t = 10^3 kg) of NO forms?

SOME SIMILAR PROBLEMS 6.57–6.66

Summary of Section 6.4

- › A thermochemical equation shows a balanced reaction *and* its ΔH value. The sign of ΔH for a forward reaction is opposite that for the reverse reaction. The magnitude of ΔH is specific for the given equation.
- › The amount of a substance and the quantity of heat specified in a thermochemical equation are thermochemically equivalent and form a conversion factor for finding the quantity of heat transferred when any amount of the substance reacts.

6.5 HESS'S LAW: FINDING ΔH OF ANY REACTION

In some cases, a reaction is difficult, even impossible, to carry out individually: it may be part of a complex biochemical process, or take place under extreme conditions, or require a change in conditions to occur. Even if we can't run a reaction in the lab, we can still find its enthalpy change. In fact, the state-function property of enthalpy (H) allows us to find ΔH of *any* reaction for which we can write an equation.

This application is based on **Hess's law**, which states that *the enthalpy change of an overall process is the sum of the enthalpy changes of its individual steps*:

$$\Delta H_{\text{overall}} = \Delta H_1 + \Delta H_2 + \cdots + \Delta H_n \quad (6.9)$$

This law follows from the fact that ΔH for a process depends only on the difference between the final and initial states. To apply Hess's law, we

- Imagine that an overall (target) reaction occurs through a series of individual reaction steps, whether or not it actually does. (Adding the steps must give the overall reaction.)
- Choose individual reaction steps, with each one having a known ΔH .
- Adjust, as needed, the equations for the individual steps, as well as their ΔH values, to obtain the overall equation.
- Add the ΔH values for the steps to get the unknown ΔH of the overall reaction. We can also find an unknown ΔH of any step by subtraction, if we know the ΔH values for the overall reaction and all the other steps.

Let's apply Hess's law to the reaction of coke (carbon in the form of graphite) and steam:

The following thermochemical equations are given:

If we can adjust equations 1, 2, and/or 3, *along with their ΔH value(s)*, so that these equations add up to equation 4, then their ΔH values will add up to the unknown ΔH_4 .

First, we identify our “target” equation, the one whose ΔH we want to find, and note the amount (mol) of each reactant and product; our “target” is equation 4. Then, we adjust equations 1, 2, and/or 3 to make them add up to equation 4:

- Equation 4 has twice as much C as equation 1, so we multiply equation 1 *and* ΔH_1 by 2; that is, we always treat the equation and its ΔH value the same.
- Equation 4 has the same amount of CO_2 on the same side of the arrow as equation 2, so we don't change equation 2.
- Equation 4 has the same amount of CH_4 as equation 3 but on opposite sides of the arrow, so we reverse equation 3 *and* change the sign of ΔH_3 .
- With the targeted amounts of reactants and products present, we add the modified equations 1, 2, and 3 and *cancel terms that appear on both sides*:

The target equation is obtained, since the 2 mol of CO and 3 mol of H_2 on each side of the arrow cancel; 1 mol of H_2O on the right cancels 1 mol of H_2O on the left, leaving 2 mol of H_2O on the left.

Because ΔH depends only on the difference between H_{final} and H_{initial} , Hess's law tells us that the difference between the enthalpies of the reactants (2 mol of C and 2 mol of H_2O) and the enthalpies of the products (1 mol of CH_4 and 1 mol of CO_2) are the same, whether the reaction takes place in one step or in a series of steps.

To summarize, calculating an unknown ΔH involves three steps:

- Identify the target equation, the step whose ΔH is unknown, and note the amount (mol) of each reactant and product.
- Adjust each equation with known ΔH values so that the target amount (mol) of each substance is on the correct side of the equation. Remember to
 - Change the sign of ΔH when you reverse an equation.
 - Multiply amount (mol) and ΔH by the same factor.
- Add the adjusted equations and their resulting ΔH values to get the target equation and its ΔH . All substances except those in the target equation must cancel.

Student Hot Spot

Student data indicate that you may struggle with the application of Hess's law. Access the eBook to view an additional Learning Resource video on this topic.

SAMPLE PROBLEM 6.9 | Using Hess's Law to Calculate an Unknown ΔH

Problem Nitrogen oxides undergo many reactions in the environment and in industry. Calculate ΔH for the following reaction of nitrogen dioxide:

given the following information:

Plan We note the amount (mol) of each substance and on which side each appears in the target equation. We adjust equation A and/or B *and* their ΔH values as needed and add them together to obtain the target equation and the unknown ΔH .

Solution Noting substances in the target equation: for reactants, there are 4 mol of NO₂ and 1 mol of O₂; for products, there are 2 mol of N₂O₅.

Adjusting the given equations:

- Equation A has half the amount of N₂O₅ as the target equation but on the opposite side of the arrow. Thus, we reverse equation A, change the sign of its ΔH , and multiply both by 2:

- Equation B has $\frac{1}{4}$ as much NO₂ as the target, and it is on the opposite side in the target. Thus, we reverse equation B, change the sign of its ΔH , and multiply both by 4:

Adding the adjusted equations to obtain the target equation:

Notice that 2 mol of O₂ cancels out on both sides, leaving 3 – 2 = 1 mol of O₂ as a reactant.

Check Obtaining the desired target equation is a sufficient check. Be sure to remember to change the *sign* of ΔH for any equation you reverse.

FOLLOW-UP PROBLEMS

6.9A Two pollutants that form in automobile exhaust are CO and NO. An environmental chemist must convert these pollutants to less harmful gases through the following reaction:

Given the following information, calculate the unknown ΔH :

6.9B Use the following reactions to find ΔH when 1 mol of HCl gas forms from its elements:

SOME SIMILAR PROBLEMS 6.70, 6.71, 6.96, and 6.105

Summary of Section 6.5

- Because H is a state function, we can use Hess's law to determine ΔH of any reaction by assuming that it is the sum of other reactions.
- After adjusting the equations of the other reactions and their ΔH values to match the substances in the target equation, we add the adjusted ΔH values to find the unknown ΔH .

6.6

STANDARD ENTHALPIES OF REACTION ($\Delta H^\circ_{\text{rxn}}$)

In this section, we see how Hess's law is used to determine the ΔH values of an enormous number of reactions. Thermodynamic variables, such as ΔH , vary somewhat with conditions. Therefore, in order to study and compare reactions, chemists have established a set of specific conditions called **standard states**:

- For a *gas*, the standard state is 1 atm* and ideal behavior.
- For a substance in *aqueous solution*, the standard state is 1 M concentration.
- For a *pure substance* (element or compound), the standard state is usually the most stable form of the substance at 1 atm and the temperature of interest. In this text (and in most thermodynamic tables), that temperature is usually 25°C (298 K).

The standard-state symbol (shown as a superscript degree sign) indicates that the variable has been measured with *all the substances in their standard states*. For example, when the enthalpy change of a reaction is measured at the standard state, it is the **standard enthalpy of reaction**, $\Delta H_{\text{rxn}}^\circ$ (also called the *standard heat of reaction*).

Formation Equations and Their Standard Enthalpy Changes

In a **formation equation**, 1 mol of a compound forms from its elements. The **standard enthalpy of formation** (ΔH_f°) (or *standard heat of formation*) is the enthalpy change for the formation equation when all the substances are in their standard states. For instance, the formation equation for methane (CH_4) is

Fractional coefficients are often used with reactants in a formation equation to obtain 1 mol of the product:

Standard enthalpies of formation have been tabulated for many substances. The values in Table 6.3 make two points (see Appendix B for a more extensive table):

1. *For an element in its standard state*, $\Delta H_f^\circ = 0$.

- The standard state for an element is the state of matter (solid, liquid, or gas) that exists at standard conditions. For most metals, like sodium, the standard state is the solid:

An additional 107.5 kJ of heat is needed to vaporize 1 mol of solid Na to gaseous Na.

For the metal mercury and the nonmetal bromine, however, the standard state is the liquid phase, since these elements exist as liquids at standard conditions:

- The standard state for molecular elements, such as the halogens, is the molecular form, not separate atoms:

An additional 121.3 kJ of heat is required to break the bonds in 1 mol of Cl_2 to produce separate Cl atoms, and 218 kJ is required to break the bonds in 1 mol of H_2 .

- Some elements exist in different forms (called *allotropes*; Chapter 14), but only one is the standard state:

2. *Most compounds have a negative ΔH_f°* . That is, most compounds have exothermic formation reactions: *under standard conditions, heat is released when most compounds form from their elements*.

*Values given to one decimal place.

*The definition of the standard state for gases has been changed to 1 bar, a slightly lower pressure than the 1 atm standard on which the data in this book are based (1 atm = 101.3 kPa = 1.013 bar). For most purposes, this makes very little difference in the standard enthalpy values.

SAMPLE PROBLEM 6.10 | Writing Formation Equations

Problem Write a balanced formation equation for each of the following and include the value of ΔH_f° : (a) $\text{AgCl}(s)$; (b) $\text{CaCO}_3(s)$; (c) $\text{HCN}(g)$.

Plan We write the elements as the reactants and 1 mol of the compound as the product, being sure all substances are in their standard states. Then, we balance the equations, keeping a coefficient of 1 for the product, and find the ΔH_f° values in Appendix B.

Solution (a) $\text{Ag}(s) + \frac{1}{2}\text{Cl}_2(g) \longrightarrow \text{AgCl}(s) \quad \Delta H_f^\circ = -127.0 \text{ kJ}$

(b) $\text{Ca}(s) + \text{C}(\text{graphite}) + \frac{3}{2}\text{O}_2(g) \longrightarrow \text{CaCO}_3(s) \quad \Delta H_f^\circ = -1207.6 \text{ kJ}$

(c) $\frac{1}{2}\text{H}_2(g) + \text{C}(\text{graphite}) + \frac{1}{2}\text{N}_2(g) \longrightarrow \text{HCN}(g) \quad \Delta H_f^\circ = 135.1 \text{ kJ}$

FOLLOW-UP PROBLEMS

6.10A Write a balanced formation equation for each of the following and include the value of ΔH_f° : (a) $\text{CH}_3\text{OH}(l)$; (b) $\text{CaO}(s)$; (c) $\text{CS}_2(l)$.

6.10B Write a balanced formation equation for each of the following and include the value of ΔH_f° : (a) $\text{CHCl}_3(l)$; (b) $\text{NH}_4\text{Cl}(s)$; (c) $\text{PbSO}_4(s)$.

SOME SIMILAR PROBLEMS 6.80 and 6.81

Determining $\Delta H_{\text{rxn}}^\circ$ from ΔH_f° Values for Reactants and Products

We can use ΔH_f° values to determine $\Delta H_{\text{rxn}}^\circ$ for any reaction. By applying Hess's law, we can imagine the reaction occurring in two steps (Figure 6.12):

Step 1. Each reactant decomposes to its elements. This is the *reverse* of the formation reaction for the *reactant*, so the standard enthalpy change is $-\Delta H_f^\circ$.

Step 2. Each product forms from its elements. This step is the formation reaction for the *product*, so the standard enthalpy change is ΔH_f° .

According to Hess's law, we add the enthalpy changes for these steps to obtain the overall enthalpy change for the reaction ($\Delta H_{\text{rxn}}^\circ$). Suppose we want $\Delta H_{\text{rxn}}^\circ$ for

We write this equation as though it were the sum of four individual equations, one for each compound. The first two show step 1, the decomposition of the reactants to their elements (*reverse* of their formation); the second two show step 2, the formation of the products from their elements:

Note that when titanium(IV) chloride and water react, the reactants don't *actually* decompose to their elements, which then recombine to form the products. But the great

Figure 6.12 The two-step process for determining $\Delta H_{\text{rxn}}^\circ$ from ΔH_f° values.

usefulness of Hess's law and the state-function concept is that $\Delta H_{\text{rxn}}^\circ$ is the difference between two state functions, $H_{\text{products}}^\circ$ minus $H_{\text{reactants}}^\circ$, so it doesn't matter how the reaction *actually* occurs. We add the individual enthalpy changes to find $\Delta H_{\text{rxn}}^\circ$ (Hess's law):

$$\begin{aligned}\Delta H_{\text{rxn}}^\circ &= \Delta H_f^\circ[\text{TiO}_2(\text{s})] + 4\Delta H_f^\circ[\text{HCl}(\text{g})] + \{-\Delta H_f^\circ[\text{TiCl}_4(\text{l})]\} + \{-2\Delta H_f^\circ[\text{H}_2\text{O}(\text{g})]\} \\ &= \underbrace{\{\Delta H_f^\circ[\text{TiO}_2(\text{s})] + 4\Delta H_f^\circ[\text{HCl}(\text{g})]\}}_{\text{Products}} - \underbrace{\{\Delta H_f^\circ[\text{TiCl}_4(\text{l})] + 2\Delta H_f^\circ[\text{H}_2\text{O}(\text{g})]\}}_{\text{Reactants}}\end{aligned}$$

For this example, the arithmetic gives $\Delta H_{\text{rxn}}^\circ = -25.4$ kJ. When we generalize the pattern, we see that *the standard enthalpy of reaction is the sum of the standard enthalpies of formation of the products minus the sum of the standard enthalpies of formation of the reactants* (see Figure 6.12):

$$\Delta H_{\text{rxn}}^\circ = \Sigma m\Delta H_f^\circ(\text{products}) - \Sigma n\Delta H_f^\circ(\text{reactants}) \quad (6.10)$$

where Σ means “sum of” and m and n are the amounts (mol) of the products and reactants given by the coefficients in the balanced equation.

SAMPLE PROBLEM 6.11 | Calculating $\Delta H_{\text{rxn}}^\circ$ from ΔH_f° Values

Problem Nitrogen dioxide reacts with oxygen to form dinitrogen pentoxide (see Sample Problem 6.9):

Calculate $\Delta H_{\text{rxn}}^\circ$ from ΔH_f° values and compare the value to that obtained using Hess's law in Sample Problem 6.9.

Plan We use values from Appendix B and apply Equation 6.10.

Solution Calculating $\Delta H_{\text{rxn}}^\circ$:

$$\begin{aligned}\Delta H_{\text{rxn}}^\circ &= \Sigma m\Delta H_f^\circ(\text{products}) - \Sigma n\Delta H_f^\circ(\text{reactants}) \\ &= \{2\Delta H_f^\circ[\text{N}_2\text{O}_5(\text{s})]\} - \{4\Delta H_f^\circ[\text{NO}_2(\text{g})] + \Delta H_f^\circ[\text{O}_2(\text{g})]\} \\ &= [(2 \text{ mol})(-43.1 \text{ kJ/mol})] - [(4 \text{ mol})(33.2 \text{ kJ/mol}) + (1 \text{ mol})(0 \text{ kJ/mol})] \\ &= [-86.2 \text{ kJ}] - [133 \text{ kJ} + 0 \text{ kJ}] = -219 \text{ kJ}\end{aligned}$$

This $\Delta H_{\text{rxn}}^\circ$ value is the same as that obtained in Sample Problem 6.9.

Check We write formation equations, with ΔH_f° values for the amounts of each compound, in the correct direction (forward for products and reverse for reactants) and find the sum:

Comment 1. A $\Delta H_{\text{rxn}}^\circ$ value obtained by using Hess's law will not always exactly match one calculated from ΔH_f° values, but the two answers will be close. 2. In this problem, we know the individual ΔH_f° values and find the sum, $\Delta H_{\text{rxn}}^\circ$. In Follow-up Problem 6.11B, we know the sum and want to find one of the ΔH_f° values.

FOLLOW-UP PROBLEMS

6.11A Tetraphosphorus decoxide reacts vigorously with water to form phosphoric acid, one of the top-10 industrial chemicals:

Calculate $\Delta H_{\text{rxn}}^\circ$ from ΔH_f° values in Appendix B.

6.11B Use the following to find ΔH_f° of methanol $\text{CH}_3\text{OH}(\text{l})$:

SOME SIMILAR PROBLEMS 6.82–6.85

The upcoming Chemical Connections essay applies ideas from this chapter to new approaches for energy utilization.

Out of necessity, we are totally rethinking our global use of energy. The dwindling supplies of our most common fuels and the environmental impact of their combustion products threaten human well-being and the survival of many other species. Energy production presents scientists, engineers, and political leaders with some of the greatest challenges of our time.

Carbon-Based Fuels, the Greenhouse Effect, and Global Warming

The **fossil fuels**—coal, petroleum, and natural gas—remain our major sources of energy, but they are *nonrenewable* because natural processes form them many orders of magnitude slower than we consume them. For much of the world's people, the main energy source is wood, one example of **biomass fuels**, which also include vegetable and animal waste. For example, in one process, chemical and/or microbial methods convert vegetable (sugarcane, corn, switchgrass) and tree waste into fuel, mainly ethanol ($\text{C}_2\text{H}_5\text{OH}$). More than 98% of gasoline used in the United States contains ethanol.

Combustion of all carbon-based fuels releases CO_2 , and over the past several decades, it has become clear that the atmospheric buildup of this gas from our increased use of these fuels is changing the climate. Let's examine the basis of climate change, its current effects, and the long-term outlook.

The natural greenhouse effect. Throughout Earth's history, CO_2 has played a key temperature-regulating role in the atmosphere. Much of the sunlight that shines on Earth is absorbed by the land and oceans and then converted to heat (infrared [IR] radiation; Figure B6.1). Like the glass of a greenhouse, CO_2 does not absorb visible light from the Sun, but it absorbs and re-emits some of the heat radiating from Earth's surface and, thus, helps warm the atmosphere. This process is called the *natural greenhouse effect* (see Figure B6.1, left). This greenhouse effect is essential to life as it has kept the average temperature of Earth 14°C (57°F) in the past; without CO_2 to absorb and re-emit heat energy, the average temperature of Earth would be -17°C (2°F)!

The enhanced greenhouse effect. As a result of intensive use of fossil fuels for the past 150 years, the amount of CO_2 in the atmosphere increased from 0.028% by volume to 0.040%. Thus, although the same quantity of solar energy passes through the atmosphere, more is being trapped as heat, which has created an *enhanced greenhouse effect* that is changing the climate through *global warming* (see Figure B6.1, right). Based on current trends, CO_2 amounts will increase to between 0.049% and 0.126% by 2100.

Modeling global warming and its effects. If this projected increase in CO_2 occurs, there are two closely related questions that must be addressed by models: (1) How much will the temperature rise? (2) How will this rise affect life on Earth?

Figure B6.1 The trapping of heat by the atmosphere. Of the total sunlight reaching Earth, some is reflected and some is absorbed and converted to IR radiation (heat). Some heat emitted by the surface is trapped by atmospheric CO_2 , creating a *natural* greenhouse effect

(left) that has been essential to life. But, largely as a result of human activity in the past 150 years, and especially the past several decades, the buildup of CO_2 and several other greenhouse gases (pie chart) has created an *enhanced* greenhouse effect (right).

Despite constantly improving models, answers are difficult to obtain. The best models predict net warming, and we are already observing the effects. Earth is now about 1.1°C warmer than it was in the late 1800s and the decade from 2011–2020 was the warmest on record, with 2016 the hottest year and 2020 the second hottest year on record. As a result of continued increases in temperature, Earth could experience increasing sea levels that will flood coastal areas and many Pacific island nations, severe drought and decreasing crop yields, more extreme weather events, and a change in plant and animal habitats that could result in decreased biodiversity.

Addressing the challenge of climate change. Since 1992 several United Nations conferences on climate change have led to agreements by numerous countries to limit greenhouse gases and resulted in financial commitments to help developing nations rely on alternative energy sources. Most recently, at the United Nations Framework Convention on Climate Change in December 2015, 195 countries adopted a legally binding global climate action plan aimed at limiting global warming to 1.5°C by reducing emission of greenhouse gases by actions such as ceasing the use of coal as a source of electricity or banning vehicles fueled by gasoline and diesel.

Carbon Capture and Alternative Energy Sources

One method to reduce greenhouse gas emissions is called *carbon capture and storage (CCS)*, a process in which CO₂ is captured and stored instead of released into the atmosphere. This process involves collecting CO₂ at the emission source or from the air and storing it away from the atmosphere, usually underground or deep in the ocean. But another way to decrease greenhouse gas emissions is to use other sources of energy that do not produce CO₂. Some alternative energy sources include:

- *Hydrogen.* The use of H₂ as an energy source holds great promise; a hydrogen-based economy is the dream of many because, even though combustion of H₂ produces less than one-third as

much energy per mole as combustion of CH₄, it yields nonpolluting water vapor. But using H₂ as a fuel presents several problems. The simplest element and most plentiful gas in the universe always occurs on Earth in compounds, most importantly with oxygen in water and carbon in hydrocarbons. One key to realizing the dream involves major improvements in the production of elemental H₂. One method involves the formation of H₂ from the decomposition of liquid water; but this process is endothermic ($\Delta H_{\text{rxn}}^{\circ} = 286 \text{ kJ/mol}$), and most direct methods that utilize electricity are costly. However, energy from flowing water, wind, and geothermal sources can provide the needed electricity. The absence of an infrastructure for transporting and storing large quantities of hydrogen is another roadblock to realizing a hydrogen-based economy. Currently, the cost of energy to cool and compress the gas to liquefy it for transfer and storage is very high.

- *Solar energy.* Solar energy is the largest carbon-free option among renewable sources. Sunlight is directly converted to electricity in a **photovoltaic cell** composed of combinations of elements that function as semiconductors such as silicon, gallium, arsenic, selenium, and tellurium.
- *Nuclear energy.* Despite ongoing problems with disposal of radioactive waste, energy from nuclear *fission*—the splitting of large, unstable atomic nuclei—is used extensively, especially in France and other parts of northern Europe. Nuclear *fusion*—the combining of small atomic nuclei—avoids the problems of fission but has been achieved so far only with a net consumption of power. (We'll discuss these processes in detail in Chapter 24.)

Engineers and chemists will continue to explore alternatives for energy production and use, but a more hopeful energy future also depends on our dedication to conserving energy by such efforts as buildings with passive solar design and the replacement of energy-wasting incandescent lightbulbs with more efficient *compact fluorescent lamps (CFLs)* or *light-emitting diodes (LEDs)*, both of which can significantly cut electricity usage.

Problems

B6.1 The combustion of H₂ produces less energy than the combustion of methane, CH₄. Use ΔH_f° values to calculate $\Delta H_{\text{rxn}}^{\circ}$ for each of the following combustion reactions:

- H₂(g) + $\frac{1}{2}$ O₂(g) → H₂O(g)
- CH₄(g) + 2O₂(g) → CO₂(g) + 2H₂O(g)

B6.2 The combustion of methane, CH₄, produces CO₂, as shown in the reaction in the previous problem. What

mass of CO₂, in kilograms, is produced by the combustion of 1.0 kg of CH₄?

B6.3 H₂ can be produced by the decomposition of water:

How much energy, in kJ, is required to produce 1000. g of H₂ in this manner?

› Summary of Section 6.6

- › Standard states are a set of specific conditions used for determining thermodynamic variables for all substances.
- › When 1 mol of a compound forms from its elements with all substances in their standard states, the enthalpy change is the standard enthalpy of formation, ΔH_f° .
- › Hess's law allows us to picture a reaction as the decomposition of the reactants to their elements followed by the formation of the products from their elements.
- › We use tabulated ΔH_f° values to find $\Delta H_{\text{rxn}}^\circ$ or use known $\Delta H_{\text{rxn}}^\circ$ and ΔH_f° values to find an unknown ΔH_f° .
- › Because of major concerns about climate change, chemists are developing energy alternatives, including hydrogen fuel and noncombustible energy sources.

CHAPTER REVIEW GUIDE

Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

Understand These Concepts

1. The distinction between a system and its surroundings (§6.1)
2. The transfer of energy to or from a system as heat and/or work (§6.1)
3. The relation of internal energy change, heat, and work (§6.1)
4. The meaning of energy conservation (§6.1)
5. The meaning of a state function and why ΔE is constant even though q and w vary (§6.1)
6. The meaning of enthalpy and the relation between ΔE and ΔH (§6.2)
7. The meaning of ΔH and the distinction between exothermic and endothermic processes (§6.2)
8. The relation between specific heat capacity and heat (§6.3)
9. How constant-pressure (coffee-cup) and constant-volume (bomb) calorimeters work (§6.3)
10. The relation between ΔH and amount of substance (§6.4)
11. The calculation of ΔH values with Hess's law (§6.5)
12. The meaning of a formation equation and the standard enthalpy of formation (§6.6)
13. How a reaction can be viewed as the decomposition of reactants followed by the formation of products (§6.6)

Master These Skills

1. Determining the change in a system's internal energy in different units (SP 6.1)
2. Calculating PV work done by or on a system (SP 6.2)
3. Drawing enthalpy diagrams for chemical and physical changes (SP 6.3)
4. Solving problems involving specific heat capacity and heat transferred in a reaction (SPs 6.4–6.7)
5. Relating the heat transferred in a reaction to the amounts of substances changing (SP 6.8)
6. Using Hess's law to find an unknown ΔH (SP 6.9)
7. Writing formation equations and using ΔH_f° values to find $\Delta H_{\text{rxn}}^\circ$ (SPs 6.10, 6.11)

Key Terms

Page numbers appear in parentheses.

biomass fuel (278)
calorie (cal) (258)
calorimeter (266)
change in enthalpy (ΔH) (262)
endothermic process (263)
enthalpy (H) (261)
enthalpy diagram (263)
exothermic process (262)
formation equation (275)
fossil fuel (278)

heat (q) (255)
heat capacity (C) (264)
Hess's law (272)
internal energy (E) (254)
joule (J) (258)
law of conservation of energy (first law of thermodynamics) (257)
molar heat capacity (C_m) (265)
photovoltaic cell (279)

pressure-volume work (PV work) (260)
specific heat capacity (c) (264)
standard enthalpy of formation (ΔH_f°) (275)
standard enthalpy of reaction ($\Delta H_{\text{rxn}}^\circ$) (275)
standard state (274)
state function (259)
surroundings (254)

system (254)
thermochemical equation (270)
thermochemistry (253)
thermodynamics (253)
work (w) (255)

Key Equations and Relationships

Page numbers appear in parentheses.

6.1 Defining the change in internal energy (254):

$$\Delta E = E_{\text{final}} - E_{\text{initial}} = E_{\text{products}} - E_{\text{reactants}}$$

6.2 Expressing the change in internal energy in terms of heat and work (255):

$$\Delta E = q + w$$

6.3 Stating the first law of thermodynamics (law of conservation of energy) (257):

$$\Delta E_{\text{universe}} = \Delta E_{\text{system}} + \Delta E_{\text{surroundings}} = 0$$

6.4 Determining the work due to a change in volume at constant pressure (PV work) (260):

$$w = -P\Delta V$$

6.5 Relating the enthalpy change to the internal energy change at constant pressure (262):

$$\Delta H = \Delta E + P\Delta V$$

6.6 Identifying the enthalpy change with the heat absorbed or released at constant pressure (262):

$$\Delta H = \Delta E + P\Delta V = q_p$$

6.7 Calculating the heat absorbed or released when a substance undergoes a temperature change or a reaction occurs (264):

$$q = c \times \text{mass} \times \Delta T$$

6.8 Calculating heat absorbed by a bomb calorimeter during a combustion reaction (269):

$$q_{\text{calorimeter}} = C_{\text{calorimeter}} \times \Delta T_{\text{calorimeter}}$$

6.9 Calculating the overall enthalpy change of a reaction (Hess's law) (272):

$$\Delta H_{\text{overall}} = \Delta H_1 + \Delta H_2 + \cdots + \Delta H_n$$

6.10 Calculating the standard enthalpy of reaction (277):

$$\Delta H_{\text{rxn}}^{\circ} = \sum m \Delta H_{\text{f}}^{\circ}(\text{products}) - \sum n \Delta H_{\text{f}}^{\circ}(\text{reactants})$$

CHAPTER PRACTICE TEST

The answers to the Practice Test problems are shown below and the full solutions can be found in the e-book.

1. What is the heat of reaction when 4.50 g of sodium reacts with excess water?

- (a) -47.6 kJ (b) -26.8 kJ (c) -36.0 kJ
(d) -72.0 kJ (e) -54.2 kJ

2. A gas does 412 J of work on its surroundings while absorbing 144 J of heat from the surroundings. Calculate ΔE for the gas.

- (a) -268 J (b) +556 J (c) -556 J (d) 112 J
(e) -112 J (f) +268 J

3. Find $\Delta H_{\text{rxn}}^{\circ}$, enthalpy change, for the reaction

Using the following information:

- (a) -4824 kJ (b) 36.4 kJ (c) 428 kJ
(d) -4030.2 kJ (e) 761 kJ

4. A 0.4358 g sample of the compound cymene, $\text{C}_{10}\text{H}_{14}$, is combusted in a bomb calorimeter with a heat capacity of 4.580 kJ/°C. The temperature of the calorimeter increased from 22.668°C to 26.830°C. Calculate ΔE for the combustion of cymene in kJ per mole of cymene.

- (a) -3168 kJ/mol (b) -4496 kJ/mol (c) -5870. kJ/mol
(d) -3.55 kJ/mol (e) -2654 kJ/mol

5. A system is compressed from an initial volume of 4.15 L to a final volume of 2.05 L by an external pressure of 0.925 atm. During the compression, the system releases 85.6 J of heat. Calculate ΔE for the system. (1 L·atm = 101.3 J)

- (a) 283 J (b) -283 J (c) -83.7 J (d) 206 J (e) 111 J

6. Use $\Delta H_{\text{f}}^{\circ}$ values to calculate $\Delta H_{\text{rxn}}^{\circ}$ for the following reaction:

- (a) -947.7 kJ (b) -191.79 kJ (c) -108.7 kJ
(d) 158.6 kJ (e) -372.3 kJ

7. A piece of titanium metal with a mass of 20.8 g is heated to 99.5°C and then dropped into a coffee-cup calorimeter containing 75.0 g of water at 21.70°C. The final temperature of the metal/water mixture is 24.30°C. Calculate the specific heat capacity of titanium. The specific heat of water is 4.18 J/g·K.

- (a) 0.429 J/g·K (b) 0.117 J/g·K (c) 0.307 J/g·K
(d) 0.616 J/g·K (e) 0.521 J/g·K

8. The reaction $\frac{1}{2}\text{N}_2(g) + \frac{1}{2}\text{O}_2(g) \rightarrow \text{NO}(g)$ is endothermic. Which of the following statements about this reaction is true?

- (a) $\Delta H_{\text{f}}^{\circ}$ of NO(g) is positive.
(b) The product has less enthalpy than the reactants.
(c) The temperature of the surroundings increases during the reaction.
(d) The system increases in volume during the reaction.

9. After absorbing 1.55 kJ of heat, the temperature of a 0.750 kg block of copper is 38.5°C. What was its initial temperature? The specific heat of copper is 0.385 J/g·K.

- (a) 35.8°C (b) 36.1°C (c) 32.2°C
(d) 33.1°C (e) 31.6°C

10. What mass of butane, C_4H_{10} , is required to heat 5.75 gallons of H_2O from 28.0°C to 100.°C? Density of H_2O = 1.00 g/mL; specific heat capacity of H_2O = 4.18 J/g·K; ΔH° of combustion of C_4H_{10} = -2660 kJ/mol.

- (a) 182 g (b) 143 g (c) 902 g
(d) 82.6 g (e) 212 g (f) 54.3 g

Answers: 1. c; 2. a; 3. b; 4. c; 5. e; 6. c; 7. e; 8. a; 9. d; 10. b

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

6.1A The liquid (system) *absorbs* heat, so q is +13.5 kJ; the system *does* work, so w is -1.8 kJ.

$$\begin{aligned}\Delta E &= q + w \\ &= [13.5 \text{ kJ} + (-1.8 \text{ kJ})] \times \frac{1000 \text{ J}}{1 \text{ kJ}} \\ &= 1.17 \times 10^4 \text{ J}\end{aligned}$$

6.1B The system *releases* heat (the surroundings absorb heat), so $q = -26.0$ kcal; the system has work *done on* it, so $w = +15.0$ Btu.

$$\begin{aligned}\Delta E &= q + w \\ &= \left(-26.0 \text{ kcal} \times \frac{4.184 \text{ kJ}}{1 \text{ kcal}} \right) + \left(15.0 \text{ Btu} \times \frac{1.055 \text{ kJ}}{1 \text{ Btu}} \right) \\ &= -93 \text{ kJ}\end{aligned}$$

6.2A P (atm) = 732 torr $\times \frac{1 \text{ atm}}{760 \text{ torr}} = 0.963 \text{ atm}$

$$w \text{ (atm}\cdot\text{L)} = -P\Delta V = -0.963 \text{ atm} \times (2.35 \text{ L} - 5.68 \text{ L}) = 3.21 \text{ atm}\cdot\text{L}$$

$$w \text{ (J)} = 3.21 \text{ atm}\cdot\text{L} \times \frac{101.3 \text{ J}}{1 \text{ atm}\cdot\text{L}} = 325 \text{ J}$$

6.2B w (atm·L) = $-P\Delta V = -5.5 \text{ atm} \times (16.3 \text{ L} - 10.5 \text{ L}) = -32 \text{ atm}\cdot\text{L}$

$$w \text{ (J)} = -32 \text{ atm}\cdot\text{L} \times \frac{101.3 \text{ J}}{1 \text{ atm}\cdot\text{L}} = -3.2 \times 10^3 \text{ J}$$

6.3A The reaction is exothermic (heat energy is released); $H_{\text{reactants}} > H_{\text{products}}$.

6.3B The process is endothermic (heat energy is absorbed); $H_{\text{products}} > H_{\text{reactants}}$.

6.4A $\Delta T = 375^\circ\text{C} - 18^\circ\text{C} = 357^\circ\text{C} = 357 \text{ K}$
 $q = c \times \text{mass} \times \Delta T = (0.897 \text{ J/g}\cdot\text{K})(7.65 \text{ g})(357 \text{ K}) = 2.45 \times 10^3 \text{ J}$

6.4B $\Delta T = 25.0^\circ\text{C} - 37.0^\circ\text{C} = -12.0^\circ\text{C} = -12.0 \text{ K}$
 $q = -177 \text{ kJ}$, since heat is released.
 $q = c \times \text{mass} \times \Delta T$

$$\text{Mass} = \frac{q}{c \times \Delta T} = \frac{-177 \text{ kJ}}{(2.394 \text{ J/g}\cdot\text{K})(-12.0 \text{ K})} \times \frac{1000 \text{ J}}{1 \text{ kJ}} = 6.16 \times 10^3 \text{ g}$$

$$\text{Volume (L)} = 6.16 \times 10^3 \text{ g} \times \frac{1 \text{ mL}}{1.11 \text{ g}} \times \frac{1 \text{ L}}{1000 \text{ mL}} = 5.55 \text{ L}$$

6.5A ΔT (solid) = $27.25^\circ\text{C} - 65.00^\circ\text{C} = -37.75^\circ\text{C} = -37.75 \text{ K}$
 ΔT (H_2O) = $27.25^\circ\text{C} - 25.55^\circ\text{C} = 1.70^\circ\text{C} = 1.70 \text{ K}$

$$\begin{aligned}c_{\text{solid}} &= -\frac{c_{\text{H}_2\text{O}} \times \text{mass}_{\text{H}_2\text{O}} \times \Delta T_{\text{H}_2\text{O}}}{\text{mass}_{\text{solid}} \times \Delta T_{\text{solid}}} \\ &= -\frac{4.18 \text{ J/g}\cdot\text{K} \times 25.00 \text{ g} \times 1.70 \text{ K}}{12.18 \text{ g} \times (-37.75 \text{ K})} \\ &= 0.386 \text{ J/g}\cdot\text{K}\end{aligned}$$

From Table 6.2, the metal is copper.

6.5B ΔT (H_2O) = $49.30^\circ\text{C} - 50.00^\circ\text{C} = -0.70^\circ\text{C} = -0.70 \text{ K}$
 $-c_{\text{solid}} \times \text{mass}_{\text{solid}} \times \Delta T_{\text{solid}} = c_{\text{H}_2\text{O}} \times \text{mass}_{\text{H}_2\text{O}} \times \Delta T_{\text{H}_2\text{O}}$

$$\begin{aligned}\Delta T_{\text{solid}} &= -\frac{c_{\text{H}_2\text{O}} \times \text{mass}_{\text{H}_2\text{O}} \times \Delta T_{\text{H}_2\text{O}}}{c_{\text{solid}} \times \text{mass}_{\text{solid}}} \\ &= -\frac{(4.18 \text{ J/g}\cdot\text{K})(75.0 \text{ g})(-0.70 \text{ K})}{(0.228 \text{ J/g}\cdot\text{K})(33.2 \text{ g})} \\ &= 29 \text{ K} = 29^\circ\text{C}\end{aligned}$$

$$\begin{aligned}\Delta T_{\text{solid}} &= T_{\text{final}} - T_{\text{initial}} \\ T_{\text{initial}} &= T_{\text{final}} - \Delta T_{\text{solid}} = 49.30^\circ\text{C} - 29^\circ\text{C} = 20.^\circ\text{C}\end{aligned}$$

(b) Total mass of solution = $(50.0 \text{ mL} + 50.0 \text{ mL}) \times 1.00 \text{ g/mL} = 100. \text{ g}$

$$\Delta T_{\text{soln}} = 25.21^\circ\text{C} - 21.90^\circ\text{C} = 3.31^\circ\text{C} = 3.31 \text{ K}$$

$$\begin{aligned}q_{\text{soln}} &= c_{\text{soln}} \times \text{mass}_{\text{soln}} \times \Delta T_{\text{soln}} = -q_{\text{rxn}} \\ &= (4.18 \text{ J/g}\cdot\text{K})(100. \text{ g})(3.31 \text{ K}) \\ &= 1384 \text{ J} \times \frac{1 \text{ kJ}}{1000 \text{ J}} = 1.384 \text{ kJ}\end{aligned}$$

$$q_{\text{rxn}} = -1.384 \text{ kJ}$$

$$\begin{aligned}\text{Amount (mol) of HCl} &= 0.500 \text{ mol HCl/L} \times 0.0500 \text{ L} \\ &= 0.0250 \text{ mol HCl}\end{aligned}$$

Similarly, we have 0.0250 mol BaCl_2 .

Finding the limiting reactant from the balanced equation:

$$\begin{aligned}\text{Amount (mol) of H}_2\text{O} &= 0.0250 \text{ mol HCl} \times \frac{2 \text{ mol H}_2\text{O}}{2 \text{ mol HCl}} \\ &= 0.0250 \text{ mol H}_2\text{O}\end{aligned}$$

$$\begin{aligned}\text{Amount (mol) of H}_2\text{O} &= 0.0250 \text{ mol Ba}(\text{OH})_2 \times \frac{2 \text{ mol H}_2\text{O}}{1 \text{ mol Ba}(\text{OH})_2} \\ &= 0.0500 \text{ mol H}_2\text{O}\end{aligned}$$

Thus, HCl is limiting.

$$\begin{aligned}\Delta H \text{ (kJ/mol H}_2\text{O)} &= \frac{q_{\text{rxn}}}{\text{mol H}_2\text{O}} = \frac{-1.384 \text{ kJ}}{0.0250 \text{ mol H}_2\text{O}} \\ &= -55.4 \text{ kJ/mol H}_2\text{O}\end{aligned}$$

6.6B Total mass of solution = $3.15 \text{ g NH}_4\text{NO}_3 + 75.0 \text{ g H}_2\text{O} = 78.15 \text{ g}$

$$\Delta T_{\text{soln}} = 21.50^\circ\text{C} - 24.60^\circ\text{C} = -3.10^\circ\text{C} = -3.10 \text{ K}$$

$$\begin{aligned}q_{\text{soln}} &= c_{\text{soln}} \times \text{mass}_{\text{soln}} \times \Delta T_{\text{soln}} = -q_{\text{rxn}} \\ &= (4.18 \text{ J/g}\cdot\text{K})(78.15 \text{ g})(-3.10 \text{ K}) \\ &= -1013 \text{ J} \times \frac{1 \text{ kJ}}{1000 \text{ J}} = -1.013 \text{ kJ}\end{aligned}$$

$$q_{\text{rxn}} = 1.013 \text{ kJ}$$

$$\begin{aligned}\Delta H \text{ (kJ/mol NH}_4\text{NO}_3) &= \frac{q_{\text{rxn}}}{\text{mol NH}_4\text{NO}_3} \\ &= \frac{1.013 \text{ kJ}}{3.15 \text{ g NH}_4\text{NO}_3} \times \frac{80.05 \text{ g NH}_4\text{NO}_3}{\text{mol NH}_4\text{NO}_3} \\ &= 25.7 \text{ kJ/mol NH}_4\text{NO}_3\end{aligned}$$

6.7A $-q_{\text{rxn}} = q_{\text{calorimeter}}$

$$q_{\text{calorimeter}} = -0.8650 \text{ g C} \times \frac{1 \text{ mol C}}{12.01 \text{ g C}} \times \frac{-393.5 \text{ kJ}}{1 \text{ mol C}} = 28.34 \text{ kJ}$$

$$q_{\text{calorimeter}} = C_{\text{calorimeter}} \times \Delta T$$

$$C_{\text{calorimeter}} = \frac{q_{\text{calorimeter}}}{\Delta T} = \frac{28.34 \text{ kJ}}{3.116 \text{ K}} = 9.09 \text{ kJ/K}$$

6.7B $\Delta T = 26.799^\circ\text{C} - 21.862^\circ\text{C} = 4.937^\circ\text{C} = 4.937 \text{ K}$

$$q_{\text{calorimeter}} = C_{\text{calorimeter}} \times \Delta T = (8.151 \text{ kJ/K})(4.937 \text{ K}) = 40.24 \text{ kJ}$$

$$q \text{ (Calories)} = 40.24 \text{ kJ} \times \frac{1 \text{ kcal}}{4.184 \text{ kJ}} \times \frac{1 \text{ Calorie}}{1 \text{ kcal}} \\ = 9.618 < 10 \text{ Calories}$$

The claim is correct.

$$\text{6.8A Mass (g) of H}_2 = -142 \text{ kJ} \times \frac{3 \text{ mol H}_2}{-91.8 \text{ kJ}} \times \frac{2.016 \text{ g H}_2}{1 \text{ mol H}_2} \\ = 9.36 \text{ g}$$

6.8B $\text{N}_2(\text{g}) + \text{O}_2(\text{g}) + 182.6 \text{ kJ} \longrightarrow 2\text{NO}(\text{g})$

$$\text{Heat (kJ)} = 3.50 \text{ t NO} \times \frac{1000 \text{ kg}}{1 \text{ t}} \times \frac{1000 \text{ g}}{1 \text{ kg}} \times \frac{1 \text{ mol NO}}{30.01 \text{ g NO}} \\ \times \frac{182.6 \text{ kJ}}{2 \text{ mol NO}} \\ = 1.06 \times 10^7 \text{ kJ absorbed}$$

6.9A Equation 1 remains the same:

Reverse equation 2 and multiply by $\frac{1}{2}$:

**6.9B** Reverse equation 1 and divide by 2:

Divide equation 2 by 2:

Reverse equation 3:

**6.10A** (a) $\text{C}(\text{graphite}) + 2\text{H}_2(\text{g}) + \frac{1}{2}\text{O}_2(\text{g}) \longrightarrow \text{CH}_3\text{OH}(\text{l})$
 $\Delta H_f^\circ = -239.2 \text{ kJ}$ **6.10B** (a) $\text{C}(\text{graphite}) + \frac{1}{2}\text{H}_2(\text{g}) + \frac{3}{2}\text{Cl}_2(\text{g}) \longrightarrow \text{CHCl}_3(\text{l})$
 $\Delta H_f^\circ = -134.1 \text{ kJ}$ 

$$\text{6.11A } \Delta H_{\text{rxn}}^\circ = \{4\Delta H_f^\circ[\text{H}_3\text{PO}_4(\text{l})]\} - \{\Delta H_f^\circ[\text{P}_4\text{O}_{10}(\text{s})] \\ + 6\Delta H_f^\circ[\text{H}_2\text{O}(\text{l})]\} \\ = [(4 \text{ mol})(-1271.7 \text{ kJ/mol})] \\ - [(1 \text{ mol})(-2984 \text{ kJ/mol}) \\ + (6 \text{ mol})(-285.8 \text{ kJ/mol})] \\ = -5086.8 \text{ kJ} - (-2984 \text{ kJ} - 1714.8 \text{ kJ}) \\ = -388 \text{ kJ}$$

6.11B Note that the ΔH_f° of $\text{O}_2(\text{g}) = 0$.

$$\Delta H_{\text{rxn}}^\circ = \{\Delta H_f^\circ[\text{CO}_2(\text{g})] + 2\Delta H_f^\circ[\text{H}_2\text{O}(\text{g})]\} - \{\Delta H_f^\circ[\text{CH}_3\text{OH}(\text{l})] \\ \Delta H_f^\circ \text{ of } \text{CH}_3\text{OH}(\text{l}) = -\Delta H_{\text{rxn}}^\circ + 2\Delta H_f^\circ[\text{H}_2\text{O}(\text{g})] + \Delta H_f^\circ[\text{CO}_2(\text{g})] \\ = 637.9 \text{ kJ} + (2 \text{ mol})(-241.8 \text{ kJ/mol}) \\ + (1 \text{ mol})(-393.5 \text{ kJ/mol}) \\ = -239.2 \text{ kJ}$$

PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

Forms of Energy and Their Interconversion

(Sample Problems 6.1 and 6.2)

Concept Review Questions

6.1 Why do heat (q) and work (w) have positive values when entering a system and negative values when leaving?

6.2 If you feel warm after exercising, have you increased the internal energy of your body? Explain.

6.3 An *adiabatic* process is one that involves no heat transfer. What is the relationship between work and the change in internal energy in an adiabatic process?

6.4 State two ways that you increase the internal energy of your body and two ways that you decrease it.

6.5 Name a common device used to accomplish each change:

- Electrical energy to thermal energy
- Electrical energy to sound energy
- Electrical energy to light energy
- Mechanical energy to electrical energy
- Chemical energy to electrical energy

6.6 In winter, an electric heater uses a certain amount of electrical energy to heat a room to 20°C. In summer, an air conditioner uses the same amount of electrical energy to cool the room to 20°C. Is the change in internal energy of the heater larger than, smaller than, or the same as that of the air conditioner? Explain.

6.7 You lift your textbook and drop it onto a desk. Describe the energy transformations (from one form to another) that occur, moving backward in time from a moment after impact.

6.8 Why is the work done when a system expands against a constant external pressure assigned a negative sign?

Skill-Building Exercises (grouped in similar pairs)

6.9 A system receives 425 J of heat from and delivers 425 J of work to its surroundings. What is the change in internal energy of the system (in J)?

6.10 A system releases 255 cal of heat to the surroundings and delivers 428 cal of work. What is the change in internal energy of the system (in cal)?

6.11 What is the change in internal energy (in J) of a system that releases 675 J of thermal energy to its surroundings and has 530 cal of work done on it?

6.12 What is the change in internal energy (in J) of a system that absorbs 0.615 kJ of heat from its surroundings and has 0.247 kcal of work done on it?

6.13 Complete combustion of 2.0 metric tons of coal to gaseous carbon dioxide releases 6.6×10^{10} J of heat. Convert this energy to (a) kilojoules; (b) kilocalories; (c) British thermal units.

6.14 Thermal decomposition of 5.0 metric tons of limestone to lime and carbon dioxide absorbs 9.0×10^6 kJ of heat. Convert this energy to (a) joules; (b) calories; (c) British thermal units.

6.15 At constant temperature, a sample of helium gas expands from 922 mL to 1.14 L against a pressure of 2.33 atm. Find w (in J) done by the gas ($101.3 \text{ J} = 1 \text{ atm} \cdot \text{L}$).

6.16 The external pressure on a gas sample is 2660 mmHg, and the volume changes from 0.88 L to 0.63 L at constant temperature. Find w (in kJ) done on the gas ($1 \text{ atm} \cdot \text{L} = 101.3 \text{ J}$).

Problems in Context

6.17 The nutritional calorie (Calorie) is equivalent to 1 kcal. One pound of body fat is equivalent to about 4.1×10^3 Calories. Express this quantity of energy in joules and kilojoules.

6.18 If an athlete expends 1950 kJ/h, how long does it take her to work off 1.0 lb of body fat? (See Problem 6.17.)

Enthalpy: Changes at Constant Pressure

(Sample Problem 6.3)

Concept Review Questions

6.19 Why is it often more convenient to measure ΔH than ΔE ?

6.20 Hot packs used by skiers produce heat via the crystallization of sodium acetate from a concentrated solution. What is the sign of ΔH for this crystallization? Is the reaction exothermic or endothermic?

6.21 Classify the following processes as exothermic or endothermic: (a) freezing of water; (b) boiling of water; (c) digestion of food; (d) a person running; (e) a person growing; (f) wood being chopped; (g) heating with a furnace.

6.22 What are the two main components of the internal energy of a substance? On what are they based?

6.23 For each process, state whether ΔH is less than (more negative), equal to, or greater than ΔE of the system. Explain.

(a) An ideal gas is cooled at constant pressure.

(b) A gas mixture reacts exothermically at fixed volume.

(c) A solid reacts exothermically to yield a mixture of gases in a container of variable volume.

Skill-Building Exercises (grouped in similar pairs)

6.24 Draw an enthalpy diagram for a general exothermic reaction; label the axis, reactants, products, and ΔH with its sign.

6.25 Draw an enthalpy diagram for a general endothermic reaction; label the axis, reactants, products, and ΔH with its sign.

6.26 Write a balanced equation and draw an enthalpy diagram for (a) combustion of 1 mol of ethane; (b) freezing of liquid water.

6.27 Write a balanced equation and draw an enthalpy diagram for (a) formation of 1 mol of sodium chloride from its elements (heat is released); (b) vaporization of liquid benzene.

6.28 Write a balanced equation and draw an enthalpy diagram for (a) combustion of 1 mol of liquid methanol (CH_3OH); (b) formation of 1 mol of NO_2 from its elements (heat is absorbed).

6.29 Write a balanced equation and draw an enthalpy diagram for (a) sublimation of dry ice [conversion of $\text{CO}_2(\text{s})$ directly to $\text{CO}_2(\text{g})$]; (b) reaction of 1 mol of SO_2 with O_2 .

6.30 The circles represent a phase change at constant temperature:

Is the value of each of the following positive (+), negative (−), or zero: (a) q_{sys} ; (b) ΔE_{sys} ; (c) ΔE_{univ} ?

6.31 The scene below represents a physical change taking place in a piston-cylinder assembly:

(a) Is w_{sys} +, −, or 0? (b) Is ΔH_{sys} +, −, or 0? (c) Can you determine whether ΔE_{surr} is +, −, or 0? Explain.

Calorimetry: Measuring the Heat of a Chemical or Physical Change

(Sample Problems 6.4 to 6.7)

Concept Review Questions

6.32 Which is larger, the specific heat capacity or the molar heat capacity of a substance? Explain.

6.33 What data do you need to determine the specific heat capacity of a substance?

6.34 Is the specific heat capacity of a substance an intensive or extensive property? Explain.

6.35 Distinguish among specific heat capacity, molar heat capacity, and heat capacity.

6.36 Both a coffee-cup calorimeter and a bomb calorimeter can be used to measure the heat transferred in a reaction. Which measures ΔE and which measures ΔH ? Explain.

Skill-Building Exercises (grouped in similar pairs)

6.37 Find q when 22.0 g of water is heated from 25.0°C to 100.°C.

6.38 Calculate q when 0.10 g of ice is cooled from 10.°C to -75°C ($c_{\text{ice}} = 2.087 \text{ J/g}\cdot\text{K}$).

6.39 A 295-g aluminum engine part at an initial temperature of 13.00°C absorbs 75.0 kJ of heat. What is the final temperature of the part (c of Al = 0.897 J/g·K)?

6.40 A 27.7-g sample of the radiator coolant ethylene glycol releases 688 J of heat. What was the initial temperature of the sample if the final temperature is 32.5°C (c of ethylene glycol = 2.394 J/g·K)?

6.41 Two iron bolts of equal mass—one at 100.°C, the other at 55°C—are placed in an insulated container. Assuming the heat capacity of the container is negligible, what is the final temperature inside the container (c of iron = 0.449 J/g·K)?

6.42 One piece of copper jewelry at 105°C has twice the mass of another piece at 45°C. Both are placed in a calorimeter of negligible heat capacity. What is the final temperature inside the calorimeter (c of copper = 0.385 J/g·K)?

6.43 When 155 mL of water at 26°C is mixed with 75 mL of water at 85°C, what is the final temperature? (Assume that no heat is released to the surroundings; d of water = 1.00 g/mL.)

6.44 An unknown volume of water at 18.2°C is added to 24.4 mL of water at 35.0°C. If the final temperature is 23.5°C, what was the unknown volume? (Assume that no heat is released to the surroundings; d of water = 1.00 g/mL.)

6.45 A 455-g piece of copper tubing is heated to 89.5°C and placed in an insulated vessel containing 159 g of water at 22.8°C. Assuming no loss of water and a heat capacity of 10.0 J/K for the vessel, what is the final temperature (c of copper = 0.385 J/g·K)?

6.46 A 30.5-g sample of an alloy at 93.0°C is placed into 50.0 g of water at 22.0°C in an insulated coffee-cup calorimeter with a heat capacity of 9.2 J/K. If the final temperature of the system is 31.1°C, what is the specific heat capacity of the alloy?

6.47 When 25.0 mL of 0.500 M H_2SO_4 is added to 25.0 mL of 1.00 M KOH in a coffee-cup calorimeter at 23.50°C, the temperature

rises to 30.17°C. Calculate ΔH in kJ per mole of H_2O formed. (Assume that the total volume is the sum of the volumes and that the density and specific heat capacity of the solution are the same as for water.)

6.48 When 20.0 mL of 0.200 M AgNO_3 and 30.0 mL of 0.100 M NaCl, both at 24.72°C, are mixed in a coffee-cup calorimeter, AgCl precipitates and the temperature of the mixture increases to 25.65°C. Calculate ΔH in kJ per mole of AgCl(s) produced. (Assume that the total volume is the sum of the volumes and that the density and specific heat capacity of the solution are the same as for water.)

6.49 When a 2.150-g sample of glucose, $\text{C}_6\text{H}_{12}\text{O}_6$, is burned in a bomb calorimeter with a heat capacity of 6.317 kJ/K, the temperature of the calorimeter increases from 23.446°C to 28.745°C. Calculate ΔE for the combustion of glucose in kJ/mol.

6.50 A chemist places 1.750 g of ethanol, $\text{C}_2\text{H}_5\text{O}$, in a bomb calorimeter with a heat capacity of 12.05 kJ/K. The sample is burned and the temperature of the calorimeter increases by 4.287°C. Calculate ΔE for the combustion of ethanol in kJ/mol.

Problems in Context

6.51 High-purity benzoic acid ($\text{C}_6\text{H}_5\text{COOH}$; ΔH for combustion = -3227 kJ/mol) is used to calibrate bomb calorimeters. A 1.221-g sample burns in a calorimeter that has a heat capacity of 6.384 kJ/°C. What is the temperature change?

6.52 Two aircraft rivets, one iron and the other copper, are placed in a calorimeter that has an initial temperature of 20.°C. The data for the rivets are as follows:

	Iron	Copper
Mass (g)	30.0	20.0
Initial T (°C)	0.0	100.0
c (J/g·K)	0.449	0.385

(a) Will heat flow from Fe to Cu or from Cu to Fe?

(b) What other information is needed to correct any measurements in an actual experiment?

(c) What is the maximum final temperature of the system (assuming the heat capacity of the calorimeter is negligible)?

6.53 A chemical engineer burned 1.520 g of a hydrocarbon in the bomb of a calorimeter (see Figure 6.10). The water temperature rose from 20.00°C to 23.55°C. If the calorimeter had a heat capacity of 11.09 kJ/K, what was the heat released (q_v) per gram of hydrocarbon?

Stoichiometry of Thermochemical Equations

(Sample Problem 6.8)

Concept Review Questions

6.54 Does a negative ΔH mean that the heat should be treated as a reactant or as a product?

6.55 Would you expect $\text{O}_2(\text{g}) \rightarrow 2\text{O}(\text{g})$ to have a positive or a negative ΔH ? Explain.

6.56 Is ΔH positive or negative when 1 mol of water vapor condenses to liquid water? Why? How does this value compare with ΔH for the vaporization of 2 mol of liquid water to water vapor?

Skill-Building Exercises (grouped in similar pairs)

6.57 Consider the following balanced thermochemical equation for a reaction sometimes used for H_2S production:

- (a) Is this an exothermic or endothermic reaction?
 (b) What is ΔH for the reverse reaction?
 (c) What is ΔH when 2.6 mol of S_8 reacts?
 (d) What is ΔH when 25.0 g of S_8 reacts?

6.58 Consider the following balanced thermochemical equation for the decomposition of the mineral magnesite:

- (a) Is heat absorbed or released in the reaction?
 (b) What is ΔH for the reverse reaction?
 (c) What is ΔH when 5.35 mol of CO_2 reacts with excess MgO ?
 (d) What is ΔH when 35.5 g of CO_2 reacts with excess MgO ?

6.59 When 1 mol of $\text{NO}(\text{g})$ forms from its elements, 90.29 kJ of heat is absorbed. (a) Write a balanced thermochemical equation. (b) What is ΔH when 3.50 g of NO decomposes to its elements?

6.60 When 1 mol of $\text{KBr}(\text{s})$ decomposes to its elements, 394 kJ of heat is absorbed. (a) Write a balanced thermochemical equation. (b) What is ΔH when 10.0 kg of KBr forms from its elements?

Problems in Context

6.61 Liquid hydrogen peroxide, an oxidizing agent in many rocket fuel mixtures, releases oxygen gas on decomposition:

How much heat is released when 652 kg of H_2O_2 decomposes?

6.62 Compounds of boron and hydrogen are remarkable for their unusual bonding (described in Section 14.5) and for their reactivity. With the more reactive halogens, for example, diborane (B_2H_6) forms trihalides even at low temperatures:

What is ΔH per kilogram of diborane that reacts?

6.63 Deterioration of buildings, bridges, and other structures through the rusting of iron costs millions of dollars a day. The actual process requires water, but a simplified equation is

- (a) How much heat is released when 0.250 kg of iron rusts?
 (b) How much rust forms when $4.85 \times 10^3 \text{ kJ}$ of heat is released?

6.64 A mercury mirror forms inside a test tube as a result of the thermal decomposition of mercury(II) oxide:

- (a) How much heat is absorbed to decompose 555 g of the oxide?
 (b) If 275 kJ of heat is absorbed, how many grams of Hg form?

6.65 Most ethylene (C_2H_4), the starting material for producing polyethylene, comes from petroleum processing. It also occurs naturally as a fruit-ripening hormone and as a component of natural gas. (a) The heat transferred during combustion of C_2H_4 is -1411 kJ/mol . Write a balanced thermochemical equation. (b) How many grams of C_2H_4 must burn to give 70.0 kJ of heat?

6.66 Sucrose ($\text{C}_{12}\text{H}_{22}\text{O}_{11}$, table sugar) is oxidized in the body by O_2 via a complex set of reactions that produces $\text{CO}_2(\text{g})$ and $\text{H}_2\text{O}(\text{g})$ and releases $5.64 \times 10^3 \text{ kJ/mol}$ sucrose. (a) Write a balanced

thermochemical equation for the overall process. (b) How much heat is released per gram of sucrose oxidized?

Hess's Law: Finding ΔH of Any Reaction

(Sample Problem 6.9)

Concept Review Questions

6.67 Express Hess's law in your own words.

6.68 What is the main application of Hess's law?

6.69 When carbon burns in a deficiency of O_2 , a mixture of CO and CO_2 forms. Carbon burns in excess O_2 to form only CO_2 , and CO burns in excess O_2 to form only CO_2 . Use ΔH values of the latter two reactions (from Appendix B) to calculate ΔH for

**Skill-Building Exercises (grouped in similar pairs)**

6.70 Calculate ΔH for

given the following reactions:

6.71 Calculate ΔH for

given the following reactions:

6.72 Write the balanced overall equation (equation 3) for the following process, calculate $\Delta H_{\text{overall}}$, and match the number of each equation with the letter of the appropriate arrow in Figure P6.72:

6.73 Write the balanced overall equation (equation 3) for the following process, calculate $\Delta H_{\text{overall}}$, and match the number of each equation with the letter of the appropriate arrow in Figure P6.73:

Figure P6.72

Figure P6.73

6.74 At a given set of conditions, 241.8 kJ of heat is released when 1 mol of $\text{H}_2\text{O}(\text{g})$ forms from its elements. Under the same conditions, 285.8 kJ is released when 1 mol of $\text{H}_2\text{O}(\text{l})$ forms from

its elements. Find ΔH for the vaporization of water at these conditions.

6.75 When 1 mol of $\text{CS}_2(l)$ forms from its elements at 1 atm and 25°C , 89.7 kJ of heat is absorbed, and it takes 27.7 kJ to vaporize 1 mol of the liquid. How much heat is absorbed when 1 mol of $\text{CS}_2(g)$ forms from its elements at these conditions?

Problems in Context

6.76 Diamond and graphite are two crystalline forms of carbon. At 1 atm and 25°C , diamond changes to graphite so slowly that the enthalpy change of the process must be obtained indirectly. Using equations from the list below, determine ΔH for

- (1) $\text{C(diamond)} + \text{O}_2(g) \longrightarrow \text{CO}_2(g) \quad \Delta H = -395.4 \text{ kJ}$
- (2) $2\text{CO}_2(g) \longrightarrow 2\text{CO}(g) + \text{O}_2(g) \quad \Delta H = 566.0 \text{ kJ}$
- (3) $\text{C(graphite)} + \text{O}_2(g) \longrightarrow \text{CO}_2(g) \quad \Delta H = -393.5 \text{ kJ}$
- (4) $2\text{CO}(g) \longrightarrow \text{C(graphite)} + \text{CO}_2(g) \quad \Delta H = -172.5 \text{ kJ}$

Standard Enthalpies of Reaction ($\Delta H^\circ_{\text{rxn}}$)

(Sample Problems 6.10 and 6.11)

Concept Review Questions

6.77 What is the difference between the standard enthalpy of formation and the standard enthalpy of reaction?

6.78 How are ΔH°_f values used to calculate $\Delta H^\circ_{\text{rxn}}$?

6.79 Make any changes needed in each of the following equations so that the enthalpy change is equal to ΔH°_f for the compound:

- (a) $\text{Cl}(g) + \text{Na}(s) \longrightarrow \text{NaCl}(s)$
- (b) $\text{H}_2\text{O}(g) \longrightarrow 2\text{H}(g) + \frac{1}{2}\text{O}_2(g)$
- (c) $\frac{1}{2}\text{N}_2(g) + \frac{3}{2}\text{H}_2(g) \longrightarrow \text{NH}_3(g)$

Skill-Building Exercises (grouped in similar pairs)

6.80 Use Table 6.3 or Appendix B to write a balanced formation equation at standard conditions for each of the following compounds: (a) CaCl_2 ; (b) NaHCO_3 ; (c) CCl_4 ; (d) HNO_3 .

6.81 Use Table 6.3 or Appendix B to write a balanced formation equation at standard conditions for each of the following compounds: (a) HI ; (b) SiF_4 ; (c) O_3 ; (d) $\text{Ca}_3(\text{PO}_4)_2$.

6.82 Calculate $\Delta H^\circ_{\text{rxn}}$ for each of the following:

- (a) $2\text{H}_2\text{S}(g) + 3\text{O}_2(g) \longrightarrow 2\text{SO}_2(g) + 2\text{H}_2\text{O}(g)$
- (b) $\text{CH}_4(g) + \text{Cl}_2(g) \longrightarrow \text{CCl}_4(l) + \text{HCl}(g)$ [unbalanced]

6.83 Calculate $\Delta H^\circ_{\text{rxn}}$ for each of the following:

- (a) $\text{SiO}_2(s) + 4\text{HF}(g) \longrightarrow \text{SiF}_4(g) + 2\text{H}_2\text{O}(l)$
- (b) $\text{C}_2\text{H}_6(g) + \text{O}_2(g) \longrightarrow \text{CO}_2(g) + \text{H}_2\text{O}(g)$ [unbalanced]

6.84 Copper(I) oxide can be oxidized to copper(II) oxide:

Given ΔH°_f of $\text{Cu}_2\text{O}(s) = -168.6 \text{ kJ/mol}$, find ΔH°_f of $\text{CuO}(s)$.

6.85 Acetylene burns in air according to the following equation:

Given ΔH°_f of $\text{CO}_2(g) = -393.5 \text{ kJ/mol}$ and ΔH°_f of $\text{H}_2\text{O}(g) = -241.8 \text{ kJ/mol}$, find ΔH°_f of $\text{C}_2\text{H}_2(g)$.

Problems in Context

6.86 The common lead-acid car battery produces a large burst of current, even at low temperatures, and is rechargeable. The reaction that occurs while recharging a “dead” battery is

(a) Use ΔH°_f values from Appendix B to calculate $\Delta H^\circ_{\text{rxn}}$.

(b) Use the following equations to check your answer to part (a):

$$\Delta H^\circ_{\text{rxn}} = -768 \text{ kJ}$$

$$\Delta H^\circ_{\text{rxn}} = -132 \text{ kJ}$$

Comprehensive Problems

6.87 Stearic acid ($\text{C}_{18}\text{H}_{36}\text{O}_2$) is a fatty acid, a molecule with a long hydrocarbon chain and an organic acid group (COOH) at the end. It is used to make cosmetics, ointments, soaps, and candles and is found in animal tissue as part of many saturated fats. In fact, when you eat meat, you are ingesting some fats containing stearic acid.

(a) Write a balanced equation for the combustion of stearic acid to gaseous products.

(b) Calculate $\Delta H^\circ_{\text{rxn}}$ for this combustion (ΔH°_f of $\text{C}_{18}\text{H}_{36}\text{O}_2 = -948 \text{ kJ/mol}$).

(c) Calculate the heat (q) released in kJ and kcal when 1.00 g of stearic acid is burned completely.

(d) A candy bar contains 11.0 g of fat and provides 100. Cal from fat; is this consistent with your answer for part (c)?

6.88 Diluting sulfuric acid with water is highly exothermic:

(a) Use Appendix B to find $\Delta H^\circ_{\text{rxn}}$ for diluting 1.00 mol of $\text{H}_2\text{SO}_4(l)$ ($d = 1.83 \text{ g/mL}$) to 1 L of 1.00 M $\text{H}_2\text{SO}_4(aq)$ ($d = 1.060 \text{ g/mL}$).

(b) Suppose you carry out the dilution in a calorimeter. The initial T is 25.0°C , and the specific heat capacity of the final solution is $3.50 \text{ J/g}\cdot\text{K}$. What is the final T ?

(c) Use the ideas of density and heat capacity to explain why you should add acid to water rather than water to acid.

6.89 A balloonist begins a trip in a helium-filled balloon in early morning when the temperature is 15°C . By mid-afternoon, the temperature is 30°C . Assuming the pressure remains at 1.00 atm, for each mole of helium, calculate the following:

(a) The initial and final volumes

(b) The change in internal energy, ΔE (Hint: Helium behaves like an ideal gas, so $E = \frac{3}{2}nRT$. Be sure the units of R are consistent with those of E .)

(c) The work (w) done by the helium (in J)

(d) The heat (q) transferred (in J)

(e) ΔH for the process (in J)

(f) Explain the relationship between the answers to parts (d) and (e).

6.90 In winemaking, the sugars in grapes undergo *fermentation* by yeast to yield $\text{CH}_3\text{CH}_2\text{OH}$ and CO_2 . During cellular *respiration* (combustion), sugar and ethanol yield water vapor and CO_2 .

(a) Using $\text{C}_6\text{H}_{12}\text{O}_6$ for sugar, calculate $\Delta H^\circ_{\text{rxn}}$ of fermentation and of respiration.

(b) Write a combustion reaction for ethanol. Which has a higher $\Delta H^\circ_{\text{rxn}}$ for combustion per mole of C, sugar or ethanol?

6.91 Three of the reactions that occur when the paraffin of a candle (typical formula $\text{C}_{21}\text{H}_{44}$) burns are as follows:

(1) Complete combustion forms CO_2 and water vapor.

- (2) Incomplete combustion forms CO and water vapor.
 (3) Some wax is oxidized to elemental C (soot) and water vapor.
 (a) Find $\Delta H_{\text{rxn}}^{\circ}$ of each reaction (ΔH_f° of $\text{C}_{21}\text{H}_{44} = -476 \text{ kJ/mol}$; use graphite for elemental carbon).
 (b) Find q (in kJ) when a 254-g candle burns completely.
 (c) Find q (in kJ) when 8.00% by mass of the candle burns incompletely and 5.00% by mass of it undergoes soot formation.

6.92 Ethylene oxide (EO) is prepared by the vapor-phase oxidation of ethylene. Its main uses are in the preparation of the anti-freeze ethylene glycol and in the production of poly(ethylene terephthalate), which is used to make beverage bottles and fibers. Pure EO vapor can decompose explosively:

Liquid EO has $\Delta H_f^{\circ} = -77.4 \text{ kJ/mol}$ and ΔH° for its vaporization = 569.4 J/g . (a) Calculate $\Delta H_{\text{rxn}}^{\circ}$ for the gas-phase reaction. (b) External heating causes the vapor to decompose at 10 bar and 93°C in a distillation column. What is the final temperature if the average specific heat capacity of the products is $2.5 \text{ J/g}\cdot^{\circ}\text{C}$?

6.93 The following scenes represent a gaseous reaction between compounds of nitrogen (blue) and oxygen (red) at 298 K :

- (a) Write a balanced equation and use Appendix B to calculate $\Delta H_{\text{rxn}}^{\circ}$.
 (b) If each molecule of product represents $1.50 \times 10^{-2} \text{ mol}$, what quantity of heat (in J) is released or absorbed?

6.94 Isooctane (C_8H_{18} ; $d = 0.692 \text{ g/mL}$) is used as the fuel in a test of a new automobile drive train.

- (a) How much energy (in kJ) is released by combustion of 20.4 gal of isooctane to gases ($\Delta H_{\text{rxn}}^{\circ} = -5.44 \times 10^3 \text{ kJ/mol}$)?
 (b) The energy delivered to the automobile's wheels at 65 mph is $5.5 \times 10^4 \text{ kJ/h}$. Assuming *all* the energy is transferred as work to the wheels, how far (in km) can the vehicle travel on the 20.4 gal of fuel?
 (c) If the actual range is 455 mi, explain your answer to (b).

6.95 Four 50.-g samples of different colorless liquids are placed in beakers at $T_{\text{initial}} = 25.00^{\circ}\text{C}$. Each liquid is heated until 450. J of heat has been absorbed; T_{final} is shown on each beaker below. Rank the liquids in order of increasing specific heat capacity.

6.96 Reaction of gaseous ClF with F_2 yields liquid ClF_3 , an important fluorinating agent. Use the following thermochemical equations to calculate $\Delta H_{\text{rxn}}^{\circ}$ for this reaction:

6.97 Silver bromide is used to coat ordinary black-and-white photographic film, whereas high-speed film uses silver iodide.

- (a) When 50.0 mL of 5.0 g/L AgNO_3 is added to a coffee-cup calorimeter containing 50.0 mL of 5.0 g/L NaI, with both solutions at 25°C , what mass of AgI forms?
 (b) Use Appendix B to find $\Delta H_{\text{rxn}}^{\circ}$.
 (c) What is ΔT_{soln} (assuming the volumes are additive and the solution has the density and specific heat capacity of water)?

6.98 The calorie (4.184 J) is defined as the quantity of energy needed to raise the temperature of 1.00 g of liquid water by 1.00°C . The British thermal unit (Btu) is defined as the quantity of energy needed to raise the temperature of 1.00 lb of liquid water by 1.00°F .

- (a) How many joules are in 1.00 Btu (1 lb = 453.6 g; $1.0^{\circ}\text{C} = 1.8^{\circ}\text{F}$)?
 (b) The *therm* is a unit of energy consumption and is defined as 100,000 Btu. How many joules are in 1.00 therm?
 (c) How many moles of methane must be burned to give 1.00 therm of energy? (Assume that water forms as a gas.)
 (d) If natural gas costs \$0.66 per therm, what is the cost per mole of methane? (Assume that natural gas is pure methane.)
 (e) How much would it cost to warm 318 gal of water in a hot tub from 15.0°C to 42.0°C by burning methane (1 gal = 3.78 L)?

6.99 When organic matter decomposes under oxygen-free (anaerobic) conditions, methane is one of the products. Thus, enormous deposits of natural gas, which is almost entirely methane, serve as a major source of fuel for home and industry.

- (a) Known deposits of natural gas can produce 5600 EJ of energy (1 EJ = 10^{18} J). Current total global energy usage is $4.0 \times 10^2 \text{ EJ}$ per year. Find the mass (in kg) of known deposits of natural gas ($\Delta H_{\text{rxn}}^{\circ}$ for the combustion of $\text{CH}_4 = -802 \text{ kJ/mol}$).
 (b) At current rates of usage, for how many years could these deposits supply the world's total energy needs?
 (c) What volume (in ft^3) of natural gas, measured at STP, is required to heat 1.00 qt of water from 25.0°C to 100.0°C (d of $\text{H}_2\text{O} = 1.00 \text{ g/mL}$; d of CH_4 at STP = 0.72 g/L)?
 (d) The fission of 1 mol of uranium (about $4 \times 10^{-4} \text{ ft}^3$) in a nuclear reactor produces $2 \times 10^{13} \text{ J}$. What volume (in ft^3) of natural gas would produce the same amount of energy?

6.100 A reaction takes place in a steel vessel within a chamber filled with argon gas. Shown below are atomic-scale views of the argon adjacent to the surface of the container wall of the reaction vessel before and after the reaction. Was the reaction exothermic or endothermic? Explain.

6.101 An aqueous waste stream with a maximum concentration of $0.50 \text{ M H}_2\text{SO}_4$ ($d = 1.030 \text{ g/mL}$ at 25°C) is neutralized by

controlled addition of 40% NaOH ($d = 1.430 \text{ g/L}$) before it goes to the process sewer and then to the chemical plant waste treatment facility. A safety review finds that the waste stream could meet a small stream of an immiscible organic compound, which could form a flammable vapor in air at 40°C . The maximum temperature reached by the NaOH solution and the waste stream is 31°C . Could the temperature increase due to the heat transferred by the neutralization cause the organic vapor to explode? Assume that the specific heat capacity of each solution is $4.18 \text{ J/g}\cdot\text{K}$.

6.102 Kerosene, a common space-heater fuel, is a mixture of hydrocarbons whose “average” formula is $\text{C}_{12}\text{H}_{26}$.

- Write a balanced equation, using the simplest whole-number coefficients, for the complete combustion of kerosene to gases.
- If $\Delta H^\circ_{\text{rxn}} = -1.50 \times 10^4 \text{ kJ}$ for the combustion equation as written in part (a), determine ΔH°_f of kerosene.
- Calculate the heat released by combustion of 0.50 gal of kerosene (d of kerosene = 0.749 g/mL).
- How many gallons of kerosene must be burned for a kerosene furnace to produce 1250. Btu (1 Btu = 1.055 kJ)?

6.103 Silicon tetrachloride is produced annually on the multikiloton scale and used in making transistor-grade silicon. It can be produced directly from the elements (reaction 1) or, more cheaply, by heating sand and graphite with chlorine gas (reaction 2). If water is present in reaction 2, some tetrachloride may be lost in an unwanted side reaction (reaction 3):

- $\text{Si}(s) + 2\text{Cl}_2(g) \longrightarrow \text{SiCl}_4(g)$
 - $\text{SiO}_2(s) + 2\text{C}(\text{graphite}) + 2\text{Cl}_2(g) \longrightarrow \text{SiCl}_4(g) + 2\text{CO}(g)$
 - $\text{SiCl}_4(g) + 2\text{H}_2\text{O}(g) \longrightarrow \text{SiO}_2(s) + 4\text{HCl}(g)$
- $\Delta H^\circ_{\text{rxn}} = -139.5 \text{ kJ}$

- Use reaction 3 to calculate the standard enthalpies of reaction of reactions 1 and 2.
- What is the standard enthalpy of reaction for a fourth reaction that is the sum of reactions 2 and 3?

6.104 One mole of nitrogen gas confined within a cylinder by a piston is heated from 0°C to 819°C at 1.00 atm.

- Calculate the work done by the expanding gas in joules ($1 \text{ J} = 9.87 \times 10^{-3} \text{ atm}\cdot\text{L}$). Assume that all the energy is used to do work.
- What would be the temperature change if the gas were heated using the same amount of energy in a container of fixed volume? (Assume that the specific heat capacity of N_2 is $1.00 \text{ J/g}\cdot\text{K}$.)

6.105 The chemistry of nitrogen oxides is very versatile. Given the following reactions and their standard enthalpy changes,

- $\text{NO}(g) + \text{NO}_2(g) \longrightarrow \text{N}_2\text{O}_3(g) \quad \Delta H^\circ_{\text{rxn}} = -39.8 \text{ kJ}$
- $\text{NO}(g) + \text{NO}_2(g) + \text{O}_2(g) \longrightarrow \text{N}_2\text{O}_5(g) \quad \Delta H^\circ_{\text{rxn}} = -112.5 \text{ kJ}$
- $2\text{NO}_2(g) \longrightarrow \text{N}_2\text{O}_4(g) \quad \Delta H^\circ_{\text{rxn}} = -57.2 \text{ kJ}$
- $2\text{NO}(g) + \text{O}_2(g) \longrightarrow 2\text{NO}_2(g) \quad \Delta H^\circ_{\text{rxn}} = -114.2 \text{ kJ}$
- $\text{N}_2\text{O}_5(s) \longrightarrow \text{N}_2\text{O}_5(g) \quad \Delta H^\circ_{\text{rxn}} = 54.1 \text{ kJ}$

calculate the standard enthalpy of reaction for

6.106 Electric generating plants transport large amounts of hot water through metal pipes, and oxygen dissolved in the water can cause a major corrosion problem. Hydrazine (N_2H_4) added to the water prevents this problem by reacting with the oxygen:

About $4 \times 10^7 \text{ kg}$ of hydrazine is produced every year by reacting ammonia with sodium hypochlorite in the *Raschig process*:

- If ΔH°_f of $\text{NaOCl}(aq) = -346 \text{ kJ/mol}$, find ΔH°_f of $\text{N}_2\text{H}_4(aq)$.
- What is the heat released when aqueous N_2H_4 is added to $5.00 \times 10^3 \text{ L}$ of water that is $2.50 \times 10^{-4} \text{ M O}_2$?

6.107 Liquid methanol (CH_3OH) can be used as an alternative fuel by pickup trucks and SUVs. An industrial method for preparing it involves the catalytic hydrogenation of carbon monoxide:

How much heat (in kJ) is released when 15.0 L of CO at 85°C and 112 kPa reacts with 18.5 L of H_2 at 75°C and 744 torr?

6.108 (a) How much heat is released when 25.0 g of methane burns in excess O_2 to form gaseous CO_2 and H_2O ?

(b) Calculate the temperature of the product mixture if the methane and air are both at an initial temperature of 0.0°C . Assume a stoichiometric ratio of methane to oxygen from the air, with air being 21% O_2 by volume (c of $\text{CO}_2 = 57.2 \text{ J/mol}\cdot\text{K}$; c of $\text{H}_2\text{O}(g) = 36.0 \text{ J/mol}\cdot\text{K}$; c of $\text{N}_2 = 30.5 \text{ J/mol}\cdot\text{K}$).

- › discovery of the electron and atomic nucleus (Section 2.3)
- › changes in the energy state of a system (Section 6.1)
- › major features of atomic structure (Section 2.4)

Every December, stargazers are treated to a dazzling spectacle known as the Geminids meteor shower (*see photo*). Unlike most meteor showers, which are caused by comets, the Geminids shower is caused by an asteroid. The source of the bright colors of the meteors is the presence of metal atoms: an orange-yellow color comes from sodium atoms, yellow color from iron atoms, blue-green from magnesium atoms, and violet from calcium atoms.

Scientists in the early 20th century, seeking to explain emissions of colored light that we see from meteors, fireworks, neon signs, and sodium-vapor streetlights, theorized a new view of matter and energy that led to new ideas about the structure of the atom. In this chapter, we will discuss the development of modern atomic theory.

IN THIS CHAPTER . . . We discuss quantum mechanics, the theory that explains the fundamental nature of energy and matter and accounts for atomic structure.

- › We consider the classical distinction between the wave properties of energy and the particle properties of matter.
- › We examine two observations—blackbody radiation and the photoelectric effect—whose explanations led to a *quantized*, or particulate, model of light.
- › We see that light emitted by excited atoms—an *atomic spectrum*—suggests an atom with distinct energy levels, and we apply spectra to chemical analysis.
- › We see how wave-particle duality, which shows that matter and energy have similar properties, and the uncertainty principle, which proposes that electron behavior can never be known exactly, led to the current model of the H atom.
- › We present quantum numbers, which specify the size, shape, and orientation of atomic orbitals, the regions an electron occupies in the H atom, as well as a quantum number that describes the spin of an electron. (In Chapter 8, we'll examine quantum numbers for atoms with more than one electron.)

7.1 THE NATURE OF LIGHT

To understand current atomic theory, we must first learn about a particular type of energy:

- **Electromagnetic radiation** (also called *electromagnetic energy* or *radiant energy*) is energy propagated by perpendicular electric and magnetic fields that increase and decrease in intensity as they move through space as waves.
- Some examples of electromagnetic radiation are visible light, x-rays, radio waves, and microwaves.

In this section, we describe some properties of electromagnetic radiation and note how they are distinguished from the particle properties of matter. But we will see that some properties blur the distinction between energy and matter, requiring a new model to explain them.

Figure 7.1 The inverse relationship of frequency and wavelength.

Figure 7.2 Differing amplitude (brightness, or intensity) of a wave.

The Wave Nature of Light

The wave properties of electromagnetic radiation are described by three variables and one constant (Figure 7.1):

1. Wavelength (Greek lambda, λ):

- The **wavelength** is the distance between identical points on adjacent waves, such as from the crest (or trough) of one wave to the crest (or trough) of the next wave.
- Wavelength has units of length such as meters or, for very short wavelengths, nanometers (nm, 10^{-9} m) or picometers (pm, 10^{-12} m). A non-SI unit called the angstrom ($\text{\AA}$, 10^{-10} m) is also sometimes used for wavelength.

2. Frequency (Greek nu, ν):

- The **frequency** of electromagnetic radiation is the number of complete waves, or cycles, that pass a given point per second.
- The unit of frequency is cycles per second, or just 1/second (s^{-1}); s^{-1} is also called a *hertz* (1 Hz = 1 s^{-1}). An FM radio station's channel is the frequency, in MHz, at which it broadcasts.

3. Speed:

- The speed of a wave is the distance it moves per unit time (meters per second, m/s).
- In a vacuum, electromagnetic radiation moves at 2.99792458×10^8 m/s (3.00×10^8 m/s to three significant figures), a *physical constant* called the **speed of light** (c).
- As Figure 7.1 shows, there is an inverse relationship between ν and λ ; since all waves are moving at the same speed, a larger number of shorter wavelengths will pass a point in a second than the number of longer wavelengths. Wave A in Figure 7.1 has a wavelength that is four times longer than that of wave C, so one wavelength of wave A passes a point in the same amount of time as four wavelengths of wave C—the frequency of wave C is four times that of wave A. Therefore, *radiation with a short wavelength has high frequency, and radiation with a long wavelength has low frequency*:

$$\nu \uparrow \lambda \downarrow \quad \text{and} \quad \nu \downarrow \lambda \uparrow$$

This inverse relationship can be expressed as:

$$c = \lambda \times \nu \quad (7.1)$$

4. Amplitude:

- The **amplitude** of a wave is the height of the crest (or depth of the trough).
- For an electromagnetic wave, the amplitude is related to the *intensity* of the radiation, or its brightness in the case of visible light.
- Light of a particular color has a specific frequency (and, thus, wavelength), but, as Figure 7.2 shows, its amplitude can vary; the light can be dimmer (lower amplitude, less intense) or brighter (higher amplitude, more intense).

The Electromagnetic Spectrum All waves of electromagnetic radiation travel at the same speed through a vacuum but differ in frequency and, therefore, wavelength. The types of radiation are arranged in order of increasing wavelength (decreasing frequency) in the **electromagnetic spectrum** (Figure 7.3). As a *continuum of radiant energy*, the spectrum is broken down into regions according to wavelength and frequency, with each region adjoining the next:

- On the short-wavelength (high-frequency) end of the spectrum are the gamma (γ) ray, x-ray, and **ultraviolet (UV)** regions. Gamma and x-rays are utilized in medicine; UV radiation is used to disinfect water and medical equipment due to its ability to kill bacteria and viruses.
- With longer wavelengths than ultraviolet light, visible light represents just a small region of the spectrum. We perceive different wavelengths (or frequencies) of visible light as different colors, from violet ($\lambda \approx 400$ nm) to red ($\lambda \approx 750$ nm). Light of a single wavelength is called *monochromatic*. White light, composed of all of the colors of visible light, is *polychromatic*, since it has light of many wavelengths.
- The region adjacent to visible light on the long-wavelength (low-frequency) end consists of **infrared (IR)** radiation. We feel infrared radiation as heat from the Sun

Figure 7.3 Regions of the electromagnetic spectrum. The visible region is expanded (and the scale made linear) to show the component colors.

and fire and it is used in devices such as electrical heaters, TV remote controls, and night vision goggles.

- Still longer wavelengths make up the microwave and radio wave regions. These types of radiation are used by microwave ovens, radios, and cell phones.

SAMPLE PROBLEM 7.1 | Interconverting Wavelength and Frequency

Problem A dental hygienist uses x-rays ($\lambda = 0.50 \text{ \AA}$) to take a series of dental radiographs while the patient listens to a radio station ($\lambda = 325 \text{ cm}$) and looks out the window at the blue sky ($\lambda = 473 \text{ nm}$). What is the frequency (in s⁻¹) of the electromagnetic radiation from each source? (Assume that the radiation travels at the speed of light, $3.00 \times 10^8 \text{ m/s}$.)

Plan We are given the wavelengths, so we use Equation 7.1 to find the frequencies. However, we must first convert the wavelengths to meters because c has units of m/s (see the road map).

Solution For the x-rays: converting from angstroms to meters,

$$\lambda = 0.50 \text{ \AA} \times \frac{10^{-10} \text{ m}}{1 \text{ \AA}} = 5.0 \times 10^{-11} \text{ m}$$

Calculating the frequency:

$$\nu = \frac{c}{\lambda} = \frac{3.00 \times 10^8 \text{ m/s}}{5.0 \times 10^{-11} \text{ m}} = 6.0 \times 10^{18} \text{ s}^{-1}$$

For the radio signal: combining steps to calculate the frequency,

$$\nu = \frac{c}{\lambda} = \frac{3.00 \times 10^8 \text{ m/s}}{325 \text{ cm} \times \frac{10^{-2} \text{ m}}{1 \text{ cm}}} = 9.23 \times 10^7 \text{ s}^{-1}$$

For the blue sky: combining steps to calculate the frequency,

$$\nu = \frac{c}{\lambda} = \frac{3.00 \times 10^8 \text{ m/s}}{473 \text{ nm} \times \frac{10^{-9} \text{ m}}{1 \text{ nm}}} = 6.34 \times 10^{14} \text{ s}^{-1}$$

Check The orders of magnitude are correct for the regions of the electromagnetic spectrum (see Figure 7.3): x-rays (10^{19} to 10^{16} s^{-1}), radio waves (10^9 to 10^4 s^{-1}), and visible light (7.5×10^{14} to $4.0 \times 10^{14} \text{ s}^{-1}$).

Comment Note that the x-ray, with the shortest wavelength, has the highest frequency, whereas the radio wave, with the longest wavelength, has the lowest frequency. The radio station here is broadcasting at $92.3 \times 10^6 \text{ s}^{-1}$, or 92.3 million Hz (92.3 MHz), about midway in the FM range.

Road Map

FOLLOW-UP PROBLEMS

Brief Solutions to **all** Follow-up Problems appear at the end of the chapter.

7.1A Some diamonds appear yellow because they contain nitrogen compounds that absorb purple light of frequency 7.23×10^{14} Hz. Calculate the wavelength (in nm and Å) of the absorbed light.

7.1B A typical television remote control emits radiation with a wavelength of 940 nm. What is the frequency (in s^{-1}) of this radiation? What type of electromagnetic radiation is this?

Wave theory explains the colors of a rainbow.

Source: Antony McAulay/Shutterstock

The Classical Distinction Between Energy and Matter In our everyday world, matter comes in chunks you can hold, weigh, and change the quantity of, piece by piece. In contrast, energy is “massless,” and its quantity can change continuously. Matter moves in specific paths, whereas radiant energy (light) travels in diffuse waves. Let’s examine some distinctions between the behavior of waves of energy and particles of matter.

1. *Refraction and dispersion.* Light of a given wavelength travels at different speeds through various transparent media—vacuum, air, water, quartz, and so forth. Therefore, when a light wave passes from one medium into another, the speed of the wave changes. Figure 7.4A shows the phenomenon known as **refraction**. If the wave strikes the boundary between media—say, between air and water—at an angle other than 90° , the change in speed causes a change in direction, and the wave continues at a different angle. The angle of refraction depends on the two media and the wavelength of the light. In the related process of *dispersion*, white light separates (disperses) into its component colors when it passes through a prism (or other refracting object) because each incoming wave is refracted at a slightly different angle.

Two of many familiar applications of refraction and dispersion involve rainbows and diamonds. You see a rainbow when sunlight entering the near surface of countless droplets is dispersed and reflected off the far surface. Red light is bent least, so it appears higher in the sky and violet lower (*see photo*). A diamond sparkles with various colors because its facets disperse and reflect the incoming light.

Figure 7.4 Different behaviors of waves and particles.

Constructive and destructive interference occur as water waves pass through two adjacent slits.

Figure 7.5 Formation of a diffraction pattern.

Source: Berenice Abbott/Science Source

In contrast to a wave of light, a particle of matter, like a pebble, does not undergo refraction. If you throw a pebble through the air into a pond, it continues to slow down gradually along a curved path after entering the water (Figure 7.4B).

2. Diffraction and interference. When a wave strikes the edge of an object, it bends around it in a phenomenon called **diffraction**. If the wave passes through a slit about as wide as its wavelength, it bends around both edges of the slit and forms a semi-circular wave on the other side of the opening (Figure 7.4C).

In contrast, when you throw a collection of particles, like a handful of sand, at a small opening, some particles hit the edge, whereas others go through the opening and continue in a narrower group (Figure 7.4D).

When waves of light pass through two adjacent slits, the nearby emerging circular waves interact through the process of *interference* to form a *diffraction pattern* (Figure 7.5):

- If the crests of the waves coincide (*in phase*), they interfere *constructively*—the amplitudes add together to form a brighter region in the diffraction pattern.
- If crests coincide with troughs (*out of phase*), they interfere *destructively*—the amplitudes cancel to form a darker region.

In contrast, particles passing through adjacent openings continue in straight paths, some colliding and moving at different angles.

The Particle Nature of Light

Three observations involving matter and light confounded physicists at the turn of the 20th century: blackbody radiation, the photoelectric effect, and atomic spectra. Explaining these phenomena required a radically new view of energy. We discuss the first two of them here and the third in Section 7.2.

Blackbody Radiation and the Quantum Theory of Energy The first of the puzzling observations involved the light given off by an object being heated.

1. Observation: blackbody radiation. When an object is heated, it emits radiation of various wavelengths, including visible light; the light of maximum intensity that is emitted, however, shifts to shorter wavelengths as the temperature increases (Figure 7.6). This shift is apparent in Figure 7.7—red light is emitted by the “cooler” coals while the “hotter”

Figure 7.6 The relationship between wavelength of blackbody radiation and temperature.

A Smoldering coal ($T \approx 1000$ K)

B Electric heating element ($T \approx 1500$ K)

C Lightbulb filament ($T > 2000$ K)

Source: (a): Ravi/Shutterstock; (b): Charles D. Winters/McGraw Hill; (c): Sam Bloomberg-Rissman/Moment/Flickr/Getty Images

lightbulb filament emits intense shorter wavelengths that include yellow and blue, mixing to give white light. These changes in intensity and wavelength of emitted light as an object is heated are characteristic of *blackbody radiation*, light given off by a hot *blackbody*.^{*} The classical wave model could not explain the relationship between the energy given off by a hot object and the wavelength of the radiation emitted.

2. *Explanation: the quantum theory.* In 1900, the German physicist Max Planck (1858–1947) developed a formula that fit the data perfectly. To find a physical explanation for his formula, Planck assumed, in a self-proclaimed “act of despair,” that the hot, glowing object could emit (or absorb) only *certain* quantities of energy:

$$E = nh\nu$$

where E is the energy of the radiation, ν is its frequency, n is a positive integer (1, 2, 3, and so on) called a **quantum number**, and h is **Planck’s constant**. With energy in joules (J) and frequency in s^{-1} , h has units of J·s:

$$h = 6.62607 \times 10^{-34} \text{ J} \cdot \text{s} = 6.626 \times 10^{-34} \text{ J} \cdot \text{s} \quad (4 \text{ sf})$$

Since the hot object emits only certain quantities of energy, and the energy must be emitted by the object’s atoms, this means that each atom *emits* only certain quantities of energy. It follows, then, that each atom *has* only certain quantities of energy. Thus, the energy of an atom is *quantized*: it occurs in fixed quantities, rather than being continuous. Each change in an atom’s energy occurs when the atom absorbs or emits one or more “packets,” or definite amounts, of energy. Each energy packet is called a **quantum** (“fixed quantity”; plural, *quanta*). A quantum of energy is equal to $h\nu$. Thus, *an atom changes its energy state by emitting (or absorbing) one or more quanta*, and the energy of the emitted (or absorbed) radiation is equal to the *difference in the atom’s energy states*:

$$\Delta E_{\text{atom}} = E_{\text{emitted (or absorbed) radiation}} = \Delta nh\nu$$

Because the atom can change its energy only by integer multiples of $h\nu$, the smallest change occurs when an atom in a given energy state changes to an adjacent state, that is, when $\Delta n = 1$:

$$\Delta E = h\nu \quad (7.2)$$

Rearranging Equation 7.1,

$$c = \nu \times \lambda \quad \text{or} \quad \frac{c}{\lambda} = \nu$$

and substituting c/λ for frequency, ν , in Equation 7.2 gives the direct relationship between wavelength and energy:

$$\Delta E = h\nu = \frac{hc}{\lambda} \quad (7.3)$$

These relationships indicate that energy is directly proportional to frequency and inversely proportional to wavelength. Short-wavelength radiation such as x-rays has high frequency and high energy, whereas long-wavelength radiation such as radio waves has low frequency and low energy, as shown in Figure 7.3.

The Photoelectric Effect and the Photon Theory of Light Despite the idea of quantization, physicists still pictured energy as traveling in waves. But the wave model could not explain the second confusing observation, the flow of current when light strikes a metal.

1. *Observation: the photoelectric effect.* When monochromatic light of sufficient frequency shines on a metal plate, a current flows, as shown in the depiction of an

^{*}A blackbody is an idealized object that absorbs all the radiation incident on it. A hollow cube with a small hole in one wall approximates a blackbody.

old-fashioned vacuum tube in Figure 7.8. It was thought that the current arises because light transfers energy that frees electrons from the metal surface. However, the effect had two confusing features, the presence of a threshold frequency and the absence of a time lag:

- *Presence of a threshold frequency.* For current to flow, the light shining on the metal must have a minimum, or threshold, *frequency*, and different metals have different minimum frequencies. But the wave theory associates the energy of light with its *amplitude* (intensity), not its frequency (color). Thus, the theory predicts that an electron would break free when it absorbed enough energy from light of *any* color.
- *Absence of a time lag.* Current flows the moment light of the minimum frequency shines on the metal, regardless of the light's intensity. But the wave theory predicts that with dim light there would be a time lag before the current flows, because the electrons would have to absorb enough energy to break free.

2. *Explanation: the photon theory.* Building on Planck's ideas, Albert Einstein (1879–1955) proposed that light itself is particulate, quantized into tiny “bundles” of energy, later called **photons**. Each atom changes its energy by an amount ΔE_{atom} when it absorbs or emits one photon, one “particle” of light, whose energy is related to its *frequency*, not its amplitude:

$$E_{\text{photon}} = h\nu = \Delta E_{\text{atom}}$$

Let's see how the photon theory explains the two features of the photoelectric effect:

- *Why there is a threshold frequency.* A beam of light consists of an enormous number of photons. The intensity (brightness) is related to the *number* of photons, but *not* to the energy of each. Therefore, a photon of a certain *minimum* energy must be absorbed to free an electron from the surface (see Figure 7.8). Since energy depends on frequency ($h\nu$), the theory predicts a threshold frequency.
- *Why there is no time lag.* An electron breaks free when it absorbs a photon of *enough* energy; it cannot break free by “saving up” energy from several photons, each having less than the minimum energy. The current is weak in dim light because fewer photons of enough energy can free fewer electrons per unit time, but some current flows *as soon as* light of sufficient energy (frequency) strikes the metal. ➤

Figure 7.8 The photoelectric effect.

SAMPLE PROBLEM 7.2

Interconverting Energy, Wavelength, and Frequency

Problem A student uses a microwave oven to heat a meal. The wavelength of the radiation is 1.20 cm. What is the energy of one photon of this microwave radiation?

Plan We know λ in centimeters (1.20 cm), so we convert to meters and then find the energy of one photon with Equation 7.3.

Solution Combining steps to find the energy of a photon:

$$E = \frac{hc}{\lambda} = \frac{(6.626 \times 10^{-34} \text{ J}\cdot\text{s})(3.00 \times 10^8 \text{ m/s})}{(1.20 \text{ cm})\left(\frac{10^{-2} \text{ m}}{1 \text{ cm}}\right)} = 1.66 \times 10^{-23} \text{ J}$$

Check Checking the order of magnitude gives

$$\frac{(10^{-33} \text{ J}\cdot\text{s})(10^8 \text{ m/s})}{10^{-2} \text{ m}} = 10^{-23} \text{ J}$$

FOLLOW-UP PROBLEMS

7.2A Calculate the wavelength (in nm) and the frequency of a photon with an energy of $8.2 \times 10^{-19} \text{ J}$, the minimum amount of energy required to dislodge an electron from the metal gold.

7.2B Calculate the energy of one photon of (a) ultraviolet light ($\lambda = 1 \times 10^{-8} \text{ m}$); (b) visible light ($\lambda = 5 \times 10^{-7} \text{ m}$); and (c) infrared light ($\lambda = 1 \times 10^{-4} \text{ m}$). What do the answers indicate about the relationship between light's wavelength and energy?

SOME SIMILAR PROBLEMS 7.9–7.12, 7.15, and 7.16

Ping-Pong Photons

This analogy helps explain why light of *insufficient* energy *cannot* free an electron from the metal surface. If one Ping-Pong ball doesn't have enough energy to knock a book off a shelf, neither does a series of Ping-Pong balls, because the book can't save up the energy from the individual impacts. But one baseball traveling at the same speed does have enough energy to move the book.

› Summary of Section 7.1

- › Electromagnetic radiation travels in waves characterized by a given wavelength (λ) and frequency (ν).
- › Electromagnetic waves travel through a vacuum at the speed of light, c (3.00×10^8 m/s), which equals $\lambda \times \nu$. Therefore, wavelength and frequency are inversely proportional to each other.
- › The intensity (brightness) of light is related to the amplitude of its waves.
- › The electromagnetic spectrum ranges from very long radio waves to very short gamma rays and includes the visible region between wavelengths 750 nm (red) and 400 nm (violet).
- › Refraction (change in a wave's speed when entering a different medium) and diffraction (bend of a wave around an edge of an object) indicate that energy is wavelike, with properties distinct from those of particles of mass.
- › Blackbody radiation and the photoelectric effect, however, are consistent with energy occurring in discrete packets, like particles.
- › Light exists as photons (quanta) whose energy is directly proportional to the frequency.
- › According to quantum theory, an atom has only certain quantities of energy ($E = nh\nu$), and it can change its energy only by absorbing or emitting a photon whose energy equals the change in the atom's energy.

7.2 ATOMIC SPECTRA

The third confusing observation about matter and energy involved the light emitted when an element is vaporized and then excited electrically. In this section, we discuss the nature of that light and see why it created a problem for the existing atomic model and how a new model solved the problem.

Line Spectra and the Rydberg Equation

When light from electrically excited gaseous atoms passes through a slit and is refracted by a prism, it does not create a *continuous spectrum*, or rainbow, as sunlight does. Instead, it creates a **line spectrum**, a series of fine lines at specific wavelengths (specific frequencies) separated by black spaces. Figure 7.9A shows the apparatus for obtaining these spectra and the line spectrum of atomic hydrogen in the visible region. Figure 7.9B shows that each element produces a unique line spectrum. For example, the brilliant color of a simple neon sign is due to intense orange and red lines in the spectrum of neon.

Features of the Rydberg Equation Spectroscopists studying atomic hydrogen identified several series of spectral lines in different regions of the electromagnetic spectrum. Figure 7.10 shows the spectral lines in the ultraviolet, visible, and infrared regions.

Using data, not theory, the Swedish physicist Johannes Rydberg (1854–1919) developed a relationship, called the *Rydberg equation*, that predicts the position and wavelength of any line in a given series:

$$\frac{1}{\lambda} = R \left(\frac{1}{n_1^2} - \frac{1}{n_2^2} \right) \quad (7.4)$$

where λ is the wavelength of the line, n_1 and n_2 are positive integers with $n_2 > n_1$, and R is the Rydberg constant ($1.097373 \times 10^7 \text{ m}^{-1}$). The value of n_1 determines the region of the electromagnetic spectrum in which the lines occur:

- $n_1 = 1$ ($n_2 = 2, 3, 4, \dots$) for the lines in the ultraviolet series:

$$\frac{1}{\lambda} = R \left(\frac{1}{1^2} - \frac{1}{n_2^2} \right), \text{ with } n_2 = 2, 3, 4, \dots$$

- $n_1 = 2$ ($n_2 = 3, 4, 5, \dots$) for the lines in the visible series.
- $n_1 = 3$ ($n_2 = 4, 5, 6, \dots$) for the lines in the infrared series.

Although the Rydberg equation predicts the wavelengths in the line spectrum of hydrogen, *it does not explain why line spectra occur*.

A

B

Figure 7.9 The line spectra (in the visible region) of several elements. **A**, The line spectrum of atomic hydrogen. **B**, Unlike the continuous spectrum of white light, emission spectra of elements, such as mercury, strontium, and neon, appear as characteristic series of colored lines.

Problems with Rutherford's Nuclear Model Almost as soon as Rutherford proposed his nuclear model (described in Chapter 2), a major problem arose. A positive nucleus and a negative electron attract each other, and for them to stay apart, the kinetic energy of the electron's motion must counterbalance the potential energy of attraction. However, the laws of classical physics say that a negative particle moving in a curved path around a positive particle *must* emit radiation and thus lose energy. If the orbiting electrons behaved in that way, they would spiral into the nucleus, and all atoms would collapse! The laws of classical physics also say that the frequency of the emitted radiation should change smoothly as the negative particle spirals inward and, thus, create a continuous spectrum, not a line spectrum. The behavior of subatomic particles seemed to violate real-world experience and accepted principles.

The Bohr Model of the Hydrogen Atom

Two years after the nuclear model was proposed, Niels Bohr (1885–1962), a young Danish physicist working in Rutherford's laboratory, suggested a model for the H atom that *did* predict the existence of line spectra.

Figure 7.10 Three series of spectral lines of atomic hydrogen.

Features of the Model Bohr used Planck's and Einstein's ideas about quantized energy to propose the following model of the hydrogen atom:

- The H atom has only certain energy levels called **stationary states**. Each state is associated with a fixed, circular orbit of the electron around the nucleus.
- Each electron orbit is assigned a value of the quantum number n (a positive integer, 1, 2, 3, . . .); n is associated with the radius of the electron orbit, which is directly related to the electron's energy: *the lower the n value, the smaller the radius of the orbit, the closer the electron is to the nucleus, and the lower the energy level.*
- The lowest energy state is called the **ground state** of the atom; for the H atom, ground state occurs when the electron is closest to the nucleus, in the first orbit ($n = 1$).
- If the electron is in any orbit farther from the nucleus ($n > 1$), the atom is in an **excited state**. With the electron in the second orbit ($n = 2$), the atom is in the first excited state; when the electron is in the third orbit ($n = 3$), the atom is in the second excited state, and so forth.
- The electron must be in one of the stationary states; it cannot be *between* states. The atom does not change its energy while the electron moves *within* an orbit.
- The electron can move from one orbit to another by absorbing or emitting a photon. The energy of the photon equals the difference in the energies of the two orbits:

$$E_{\text{photon}} = \Delta E_{\text{atom}} = E_{\text{final}} - E_{\text{initial}}$$

- If an H atom *absorbs* a photon whose energy equals the *difference* between lower and higher energy levels, the electron moves to the outer (higher energy) orbit.
- If an H atom in a higher energy level (with its electron in a farther orbit) returns to a lower energy level (electron in a closer orbit), the atom *emits* a photon whose energy equals the difference between the two levels.

Figure 7.11 shows a staircase analogy for the stationary states in the hydrogen atom. The atom can absorb energy to move the electron farther from the nucleus to a higher energy level or the atom can emit energy to move the electron into a lower energy level closer to the nucleus. Note that the energy difference between two consecutive orbits decreases as n increases.

How the Model Explains Line Spectra Bohr's model provides an explanation for the creation of a line vs. continuous spectrum:

Figure 7.11 A quantum “staircase” as an analogy for atomic energy levels. Note that the electron can move up or down one or more steps at a time but cannot lie *between* steps.

- When an electron moves to an orbit closer to the nucleus, the atom's energy changes from a higher state to a lower state, resulting in a loss of a *specific* quantity of energy (ΔE); that energy is *emitted* as a photon of a *specific* wavelength, producing a line in the atom's line spectrum: $\Delta E_{\text{photon}} = hc/\lambda$.
- Since there are only certain energy levels in the atom, only certain quantities of energy (and photons of certain wavelengths) can be emitted as the electron transitions from one orbit to another. *Since an atom's energy is not continuous, but rather has only certain states, an atomic spectrum is not continuous.*

Figure 7.12A shows how Bohr's model accounts for three series of spectral lines of hydrogen. When a sample of gaseous H atoms is excited, the atoms absorb different quantities of energy. Each atom has one electron, but there are so many atoms in the whole sample that all the energy levels (orbits) have electrons. As electrons transition from one energy level to another, the n value of the final energy level determines the region of the electromagnetic spectrum in which the emission line falls.

- When electrons drop from outer orbits ($n = 2, 3, \dots$) to the $n = 1$ orbit (ground state), photons with the energy of ultraviolet radiation are emitted, creating the *ultraviolet* series of lines. Figure 7.12B shows how the specific lines in the ultraviolet series appear.

A

B

Figure 7.12 The Bohr explanation of three series of spectral lines emitted by the H atom. **A**, In a given series, the outer electron drops to the same inner orbit (the same value of n_1 in the Rydberg equation). **B**, An energy diagram shows how the ultraviolet series arises.

- When electrons drop to the $n = 2$ orbit (first excited state), photons of lower energy (longer wavelength) visible radiation are emitted, creating the *visible* series of lines.
- When electrons drop to the $n = 3$ orbit (second excited state), photons of even lower energy, corresponding to infrared radiation, are emitted, resulting in the *infrared* series of lines.

Student Hot Spot

Student data indicate that you may struggle with the concept of line spectra. Access the eBook to view an additional Learning Resource video on this topic.

Limitations of the Model Despite its great success in accounting for the spectral lines of the H atom, the Bohr model failed to predict the spectrum of any other atom. The reason is that it is a *one-electron model*: it works beautifully for the H atom and for other one-electron species, such as He^+ ($Z = 2$), Li^{2+} ($Z = 3$), and Be^{3+} ($Z = 4$). It fails completely for atoms with more than one electron, because the electron-electron repulsions and additional nucleus-electron attractions that are present create much more complex interactions. But, even more fundamentally, as we'll see in Section 7.4, *electrons do not move in fixed, defined orbits*. Even though, as a picture of the atom, the Bohr model is incorrect, we still use the terms *ground state* and *excited state* and retain the central idea that *the energy of an atom occurs in discrete levels and it changes when the atom absorbs or emits a photon of specific energy*.

The Energy Levels of the Hydrogen Atom

Bohr's work leads to an equation for calculating the energy levels of an atom:

$$E = -2.18 \times 10^{-18} \text{ J} \left(\frac{Z^2}{n^2} \right)$$

where Z is the charge of the nucleus. For the H atom, $Z = 1$, so we have

$$\begin{aligned} E &= -2.18 \times 10^{-18} \text{ J} \left(\frac{1^2}{n^2} \right) \\ &= -2.18 \times 10^{-18} \text{ J} \left(\frac{1}{n^2} \right) \end{aligned}$$

A Tabletop Analogy for Defining the Energy of a System

If you define the zero point of a book's potential energy when the book is on a table, the potential energy is negative when the book is on the floor.

Therefore, the energy of the ground state ($n = 1$) of the H atom is

$$E = -2.18 \times 10^{-18} \text{ J} \left(\frac{1}{1^2} \right) \\ = -2.18 \times 10^{-18} \text{ J}$$

The negative sign for the energy (also used on the axis in Figure 7.12B) appears because we *define* the zero point of the atom's energy when *the electron is completely removed from the nucleus*. Thus, $E = 0$ when $n = \infty$, so $E < 0$ for any smaller n . ◀

Applying Bohr's Equation for the Energy Levels of an Atom We can use the equation for the energy levels to calculate the energy and wavelength of a photon that is emitted or absorbed when an electron moves from one energy level to another:

1. *Finding the difference in energy between two levels.* By subtracting the initial energy level of the atom from its final energy level, we find the change in energy when the electron moves between the two levels:

$$\Delta E = E_{\text{final}} - E_{\text{initial}} = -2.18 \times 10^{-18} \text{ J} \left(\frac{1}{n_{\text{final}}^2} - \frac{1}{n_{\text{initial}}^2} \right) \quad (7.5)$$

Note that, since n is in the denominator,

- When the atom emits energy, the electron moves closer to the nucleus ($n_{\text{final}} < n_{\text{initial}}$), so the atom's final energy is a *larger* negative number and ΔE is negative.
- When the atom absorbs energy, the electron moves away from the nucleus ($n_{\text{final}} > n_{\text{initial}}$), so the atom's final energy is a *smaller* negative number and ΔE is positive. (Analogously, in Chapter 6, you saw that, when the system releases heat, ΔH is negative, and when it absorbs heat, ΔH is positive.)

2. *Finding the wavelength of a spectral line.* Once we know ΔE from Equation 7.5, we find the wavelengths of the spectral lines of the H atom from Equation 7.3:

$$\lambda = \frac{hc}{\Delta E}$$

Alternatively, we combine Equation 7.3 with 7.5 and use Bohr's model to derive Rydberg's equation (Equation 7.4):

$$\begin{aligned} \frac{hc}{\lambda} = \Delta E &= -2.18 \times 10^{-18} \text{ J} \left(\frac{1}{n_{\text{final}}^2} - \frac{1}{n_{\text{initial}}^2} \right) \\ \frac{1}{\lambda} &= \frac{-2.18 \times 10^{-18} \text{ J}}{hc} \left(\frac{1}{n_{\text{final}}^2} - \frac{1}{n_{\text{initial}}^2} \right) \\ &= \frac{-2.18 \times 10^{-18} \text{ J}}{(6.626 \times 10^{-34} \text{ J}\cdot\text{s})(3.00 \times 10^8 \text{ m/s})} \left(\frac{1}{n_{\text{final}}^2} - \frac{1}{n_{\text{initial}}^2} \right) \\ &= 1.10 \times 10^7 \text{ m}^{-1} \left(\frac{1}{n_1^2} - \frac{1}{n_2^2} \right) \end{aligned}$$

SAMPLE PROBLEM 7.3 Determining ΔE and λ of an Electron Transition

Problem A hydrogen atom absorbs a photon of UV light (see Figure 7.12), and its electron enters the $n = 4$ energy level. Calculate (a) the change in energy of the atom and (b) the wavelength (in nm) of the absorbed photon.

Plan (a) The H atom absorbs energy, so $E_{\text{final}} > E_{\text{initial}}$. We are given $n_{\text{final}} = 4$, and Figure 7.12 shows that $n_{\text{initial}} = 1$ because a UV photon is absorbed. We apply Equation 7.5 to find ΔE . (b) Once we know ΔE , we find the wavelength (in m) with Equation 7.3. Then we convert from meters to nanometers.

Solution (a) Substituting the known values into Equation 7.5:

$$\begin{aligned}\Delta E &= -2.18 \times 10^{-18} \text{ J} \left(\frac{1}{n_{\text{final}}^2} - \frac{1}{n_{\text{initial}}^2} \right) = -2.18 \times 10^{-18} \text{ J} \left(\frac{1}{4^2} - \frac{1}{1^2} \right) \\ &= -2.18 \times 10^{-18} \text{ J} \left(\frac{1}{16} - \frac{1}{1} \right) = 2.04 \times 10^{-18} \text{ J}\end{aligned}$$

(b) Using Equation 7.3 to solve for λ :

$$\Delta E = \frac{hc}{\lambda}$$

therefore,

$$\lambda = \frac{hc}{\Delta E} = \frac{(6.626 \times 10^{-34} \text{ J}\cdot\text{s})(3.00 \times 10^8 \text{ m/s})}{2.04 \times 10^{-18} \text{ J}} = 9.74 \times 10^{-8} \text{ m}$$

Converting m to nm:

$$\begin{aligned}\lambda &= 9.74 \times 10^{-8} \text{ m} \times \frac{1 \text{ nm}}{10^{-9} \text{ m}} \\ &= 97.4 \text{ nm}\end{aligned}$$

Check (a) The energy change is positive, which is consistent with absorption of a photon. (b) The wavelength is within the UV region (about 10–380 nm).

Comment 1. We could instead use Equation 7.4 to find the wavelength (recall that, in this equation, $n_2 > n_1$):

$$\begin{aligned}\frac{1}{\lambda} &= R \left(\frac{1}{n_1^2} - \frac{1}{n_2^2} \right) \\ &= 1.097373 \times 10^7 \text{ m}^{-1} \left(\frac{1}{1^2} - \frac{1}{4^2} \right) \\ \frac{1}{\lambda} &= 1.028787 \times 10^7 \text{ m}^{-1} \\ \lambda \text{ (m)} &= \frac{1}{1.028787 \times 10^7 \text{ m}^{-1}} = 9.72 \times 10^{-8} \text{ m} \\ \lambda \text{ (nm)} &= 9.72 \times 10^{-8} \text{ m} \times \frac{1 \text{ nm}}{10^{-9} \text{ m}} = 97.2 \text{ nm}\end{aligned}$$

2. In Follow-up Problem 7.3A, note that, if ΔE is negative (the atom loses energy), we use its absolute value, $|\Delta E|$, to calculate λ because λ must have a positive value.

FOLLOW-UP PROBLEMS

7.3A A hydrogen atom with its electron in the $n = 6$ energy level emits a photon of IR light. Calculate (a) the change in energy of the atom and (b) the wavelength (in Å) of the photon.

7.3B An electron in the $n = 6$ energy level of an H atom drops to a lower energy level; the atom emits a photon of wavelength 410. nm. (a) What is ΔE for this transition in 1 mol of H atoms? (b) To what energy level did the electron move?

SOME SIMILAR PROBLEMS 7.23–7.28, 7.31, and 7.32

Spectrometric analysis of the H atom led to the Bohr model, the first step toward our current model of the atom. From its use by 19th-century chemists as a means of identifying elements and compounds, spectrometry has developed into a major tool of modern chemistry (see Tools of the Laboratory).

The use of spectral data to identify and quantify substances is essential to modern chemical analysis. The terms *spectroscopy* and **spectrometry** refer to a large group of instrumental techniques that obtain spectra to gather data on a substance's atomic and molecular energy levels.

Types of Spectra

Line spectra occur in two important types:

1. An **emission spectrum**, such as the H atom line spectrum, occurs when atoms in an excited state *emit* photons as they return to a lower energy state. Some elements produce an intense spectral line (or several closely spaced ones) that is evidence of their presence. **Flame tests**, performed by placing a granule of an ionic compound or a drop of its solution in a flame, rely on these intense emissions (Figure B7.1A), and some colors of fireworks are due to the same elements (Figure B7.1B). The colors of sodium-vapor and mercury-vapor streetlamps are due to intense emissions lines in these elements' spectra.

2. An **absorption spectrum** is produced when atoms *absorb* photons of certain wavelengths and become excited. When white light passes through sodium vapor, for example, the absorption

Figure B7.1 Flame tests and fireworks. **A**, The flame's color is due to intense emission by the element of light of a particular wavelength. **B**, Fireworks display emissions similar to those seen in flame tests.

Figure B7.2 Emission and absorption spectra of sodium atoms.

The wavelengths of the bright emission lines correspond to those of the dark absorption lines because both are created by the same energy change: $\Delta E_{\text{emission}} = -\Delta E_{\text{absorption}}$. (Only the two most intense lines in the Na spectra are shown.)

spectrum shows dark lines at the same wavelengths as the yellow-orange lines in sodium's emission spectrum (Figure B7.2).

Because elements and compounds have unique line spectra, astronomers can use such spectra to determine the composition of the Sun, planets, stars, comets, and other celestial bodies. For example, the presence of helium (*helios*, Greek for “sun”) in the Sun was discovered by examining sunlight with a spectroscope.

Basic Instrumentation

Instruments that are based on absorption spectra are much more common than those based on emission spectra because many substances absorb relatively few wavelengths, so their absorption spectra are more characteristic, and absorption is less destructive of fragile molecules.

Design differences depend on the region of the electromagnetic spectrum used to irradiate the sample, but all modern spectrometers have components that perform the same basic functions (Figure B7.3). (We discuss infrared spectroscopy and nuclear magnetic resonance spectroscopy in later chapters.)

Identifying and Quantifying a Substance

In chemical analysis, spectra are used to identify a substance and/or quantify the amount in a sample. Visible light is often used for colored substances, because they absorb only some of the wavelengths. A leaf looks green, for example, because its chlorophyll absorbs red and blue light strongly but green light weakly, so most of the green light is reflected.

Figure B7.3 Components of a typical spectrometer.

Figure B7.4 shows the visible absorption spectrum of chlorophyll *a* in ether solution. The shape of the curve and the wavelengths of the major peaks are characteristic of chlorophyll *a*. The curve varies in height because chlorophyll *a* absorbs light of different wavelengths to different extents. The absorptions appear as broad bands, rather than as the distinct lines seen on absorption spectra of elements, because there are greater numbers and types of energy levels within a molecule as well as interactions between molecules and solvent.

Figure B7.4 Measuring chlorophyll *a* concentration in leaf extract. **A**, The spectrometer is set to measure the strong absorption at 663 nm

In addition to identifying a substance, a spectrometer can be used to measure its concentration because *absorbance*, the quantity of light of a given wavelength absorbed by a substance, is *proportional to the number of molecules*. Suppose you want to determine the concentration of chlorophyll *a* in a leaf extract. You select a strongly absorbed wavelength from the compound's spectrum (such as 663 nm in Figure B7.4A), measure the absorbance of the *unknown* solution, and compare it with the absorbances of a series of solutions of *known* concentration (Figure B7.4B).

in the chlorophyll *a* spectrum. **B**, The absorbance from the leaf extract is compared to a series of known standards.

Problems

B7.1 The sodium salt of 2-quinizarinsulfonic acid forms a complex with Al^{3+} that absorbs strongly at 560 nm.

(a) Use the data below to draw a plot of absorbance vs. concentration of the complex in solution and find the slope and y-intercept:

Concentration (M)	Absorbance (560 nm)
1.0×10^{-5}	0.131
1.5×10^{-5}	0.201
2.0×10^{-5}	0.265
2.5×10^{-5}	0.329
3.0×10^{-5}	0.396

(b) When 20.0 mL of a solution of this complex is diluted with water to 150. mL, the measured absorbance is 0.236. Find the concentrations of the diluted solution and of the original solution.

B7.2 In fireworks displays, flame tests, and other emission events, light of a given wavelength may indicate the presence of a particular element or ion. What are the frequency and color of the light associated with each of the following?

- Li , $\lambda = 671 \text{ nm}$
- Cs^+ , $\lambda = 453 \text{ nm}$
- Na , $\lambda = 589 \text{ nm}$

Summary of Section 7.2

- Unlike sunlight, light emitted by electrically excited atoms of elements and refracted through a prism appears as separate spectral lines.
- Spectroscopists use an empirical formula (the Rydberg equation) to determine the wavelength of a spectral line. Atomic hydrogen displays several series of spectral lines.
- To explain the existence of line spectra, Bohr proposed that an electron moves in fixed orbits. It moves from one orbit to another when the atom absorbs or emits a photon whose energy equals the difference in energy levels (orbits).
- Bohr's model predicts only the spectrum of the H atom and other one-electron species. Despite this, Bohr was correct that an atom's energy is quantized.
- Spectrometry is an instrumental technique that uses emission and absorption spectra to identify substances and measure their concentrations.

7.3 THE WAVE-PARTICLE DUALITY OF MATTER AND ENERGY

Bohr's model was a perfect case of fitting theory to data: he *assumed* that an atom has only certain energy levels in order to *explain* line spectra. However, Bohr had no theoretical basis for the assumption. Several breakthroughs in the early 1920s provided that basis and blurred the distinction between matter (chunky and massive) and energy (diffuse and massless). Some results showed that matter has wavelike properties while others showed energy as particle-like. These remarkable ideas are the key to understanding our modern atomic model.

The Wave Nature of Electrons

Attempting to explain why an atom has fixed energy levels, a French physics student, Louis de Broglie (1892–1987), considered other systems that display only certain allowed motions, such as the vibrations of a plucked guitar string. Figure 7.13 shows that, because the end of the string is fixed, only certain vibrational frequencies (and wavelengths) are allowable when the string is plucked. De Broglie proposed that, *if energy is particle-like, perhaps matter is wavelike*. He reasoned that, *if electrons have wavelike motion* in orbits of fixed radii, they have only certain allowable frequencies and energies.

De Broglie combined Albert Einstein's equation for mass-energy equivalence and the equation for the energy of a photon:

$$E = mc^2 \quad \text{and} \quad E = \frac{hc}{\lambda} \quad \text{so} \quad mc^2 = \frac{hc}{\lambda} \quad \text{or} \quad \lambda = \frac{hc}{mc^2} = \frac{h}{mc}$$

Using this relationship, the wavelength of any particle of mass m —whether planet, baseball, or electron—moving at speed u can be calculated:

$$\lambda = \frac{h}{mu} \quad (7.6)$$

According to this equation for the **de Broglie wavelength**, *matter behaves as though it moves in a wave*. An object's wavelength is *inversely* proportional to its mass, so heavy objects such as planets and baseballs have wavelengths *many* orders of magnitude smaller than the objects themselves, too small to be detected, in fact (Table 7.1).

Figure 7.13 Wave motion in restricted systems. **A**, One half-wavelength ($\lambda/2$) is the “quantum” of the guitar string's vibration. With string length L fixed by a finger on the fret, allowed vibrations occur when L is a whole-number multiple (n) of $\lambda/2$.

B, In a circular electron orbit, only whole numbers of wavelengths are allowed ($n = 3$ and $n = 5$ are shown). A wave with a fractional number of wavelengths (such as $n = 3\frac{1}{3}$) is “forbidden” because it dies out through overlap of crests and troughs.

Table 7.1 | The de Broglie Wavelengths of Several Objects

Substance	Mass (g)	Speed (m/s)	λ (m)
Slow electron	9×10^{-28}	1.0	7×10^{-4}
Fast electron	9×10^{-28}	5.9×10^6	1×10^{-10}
Alpha particle	6.6×10^{-24}	1.5×10^7	7×10^{-15}
1-gram mass	1.0	0.01	7×10^{-29}
Baseball	142	40.0	1×10^{-34}
Earth	6.0×10^{27}	3.0×10^4	4×10^{-63}

SAMPLE PROBLEM 7.4 | Calculating the de Broglie Wavelength of an Electron

Problem Find the de Broglie wavelength of an electron with a speed of 1.00×10^6 m/s (electron mass = 9.11×10^{-31} kg; $h = 6.626 \times 10^{-34}$ kg·m²/s).

Plan We know the speed (1.00×10^6 m/s) and mass (9.11×10^{-31} kg) of the electron, so we substitute these into Equation 7.6 to find λ .

Solution

$$\lambda = \frac{h}{mu} = \frac{6.626 \times 10^{-34} \text{ kg} \cdot \text{m}^2/\text{s}}{(9.11 \times 10^{-31} \text{ kg})(1.00 \times 10^6 \text{ m/s})} = 7.27 \times 10^{-10} \text{ m}$$

Check The order of magnitude and the unit seem correct:

$$\lambda \approx \frac{10^{-33} \text{ kg} \cdot \text{m}^2/\text{s}}{(10^{-30} \text{ kg})(10^6 \text{ m/s})} = 10^{-9} \text{ m}$$

Comment As you'll see in the upcoming discussion, such fast-moving electrons, with wavelengths in the range of atomic sizes, exhibit remarkable properties.

FOLLOW-UP PROBLEMS

7.4A (a) What is the speed of an electron that has a de Broglie wavelength of 100. nm (electron mass = 9.11×10^{-31} kg)?

(b) At what speed would a 45.9-g golf ball need to move to have a de Broglie wavelength of 100. nm?

7.4B Find the de Broglie wavelength of a 39.7-g racquetball traveling at a speed of 55 mi/h.

SOME SIMILAR PROBLEMS 7.39(a), 7.40(a), and 7.41–7.42

If electrons travel in waves, they should exhibit diffraction and interference. A fast-moving electron has a wavelength of about 10^{-10} m, so a beam of such electrons should be diffracted by the spaces between atoms in a crystal—which measure about 10^{-10} m. In 1927, C. Davisson and L. Germer guided a beam of x-rays and then a beam of electrons at a nickel crystal and obtained two diffraction patterns; Figure 7.14 shows such patterns for aluminum. Thus, electrons—particles with mass and charge—create diffraction patterns, just as electromagnetic waves do.

A major application of electrons traveling in waves is the *electron microscope*. Its great advantage over light microscopes is that high-speed electrons have much smaller wavelengths than visible light, which allow much higher resolution. In a scanning electron microscope (SEM), an electron beam scans the specimen, knocking electrons from it that create a current, which generates an image that looks like the object's surface (Figure 7.15).

The Particle Nature of Photons

If electrons have properties of energy, do photons have properties of matter? The de Broglie equation suggests that we can calculate the momentum (p), the product of

**A****B**

Source: NIAID-RML/American Photo Archive/Alamy Stock Photo

mass and speed, for a photon. Substituting the speed of light (c) for speed u in Equation 7.6 and solving for p gives

$$\lambda = \frac{h}{mc} = \frac{h}{p} \quad \text{and} \quad p = \frac{h}{\lambda}$$

The inverse relationship between p and λ in this equation means that shorter wavelength (higher energy) photons have greater momentum. Thus, a decrease in a photon's momentum should appear as an increase in its wavelength. In 1923, Arthur Compton directed a beam of x-ray photons at graphite and observed an increase in the wavelength of the reflected photons. Thus, just as billiard balls transfer momentum when they collide, the photons transferred momentum to the electrons in the carbon atoms of the graphite. In this experiment, photons behaved as particles.

Wave-Particle Duality

Classical experiments had shown matter to be particle-like and energy to be wavelike. But results on the atomic scale show electrons moving in waves and photons having momentum. Thus, every property of matter is also a property of energy. The truth is that *both* matter and energy show *both* behaviors: each possesses both “faces.” In some experiments, we observe one face; in other experiments, we observe the other face. Our everyday distinction between matter and energy is meaningful in the macroscopic world, but *not* in the atomic world. The distinction is in our minds and the limited definitions we have created, not inherent in nature. This dual character of matter and energy is known as the **wave-particle duality**—particles have wavelike properties, and energy has particle-like properties. Figure 7.16 summarizes the theories and observations that led to this new understanding.

Figure 7.16 Major observations and theories leading from classical theory to quantum theory.

Heisenberg's Uncertainty Principle

In classical physics, a moving particle has a definite location at any instant, whereas a wave is spread out in space. If an electron has the properties of *both* a particle and a wave, can we determine its position in the atom? In 1927, the German physicist Werner Heisenberg (1901–1976) postulated the **uncertainty principle**, which states that it is impossible to know simultaneously the position *and* momentum (mass times speed) of a particle. For a particle with constant mass m , the principle is expressed mathematically as

$$\Delta x \cdot m \Delta u \geq \frac{h}{4\pi} \quad (7.7)$$

where Δx is the uncertainty in position, Δu is the uncertainty in speed, and h is Planck's constant. The more accurately we know the position of the particle (smaller Δx), the less accurately we know its speed (larger Δu), and vice versa. The best-case scenario is that we know the product of these uncertainties, which is equal to $h/4\pi$.

For a macroscopic object like a baseball, Δx and Δu are insignificant because the mass is enormous compared with $h/4\pi$. Thus, if we know the position and speed of a pitched baseball, we can use the laws of motion to predict its trajectory and whether it will be a ball or a strike. However, using the position and speed of an electron to find its trajectory is a very different proposition, as Sample Problem 7.5 demonstrates.

SAMPLE PROBLEM 7.5 | Applying the Uncertainty Principle

Problem An electron moving near an atomic nucleus has a speed of $6 \times 10^6 \text{ m/s} \pm 1\%$. What is the uncertainty in its position (Δx)?

Plan The uncertainty in the speed (Δu) is given as 1%, so we multiply u ($6 \times 10^6 \text{ m/s}$) by 0.01 to calculate the value of Δu , substitute that value into Equation 7.7, and solve for the uncertainty in position (Δx).

Solution Finding the uncertainty in speed, Δu :

$$\Delta u = 1\% \text{ of } u = 0.01(6 \times 10^6 \text{ m/s}) = 6 \times 10^4 \text{ m/s}$$

Calculating the uncertainty in position, Δx :

$$\Delta x \cdot m \Delta u \geq \frac{h}{4\pi}$$

Thus,

$$\Delta x \geq \frac{h}{4\pi m \Delta u} \geq \frac{6.626 \times 10^{-34} \text{ kg} \cdot \text{m}^2/\text{s}}{4\pi(9.11 \times 10^{-31} \text{ kg})(6 \times 10^4 \text{ m/s})} \geq 1 \times 10^{-9} \text{ m}$$

Check Be sure to round off and check the order of magnitude of the answer:

$$\Delta x \geq \frac{10^{-33} \text{ kg} \cdot \text{m}^2/\text{s}}{(10^1)(10^{-30} \text{ kg})(10^5 \text{ m/s})} = 10^{-9} \text{ m}$$

Comment The uncertainty in the electron's position is about 10 times greater than the diameter of the entire atom (10^{-10} m)! Therefore, we have no precise idea where in the atom the electron is located. In Follow-up Problem 7.5A, you'll see whether an umpire has any better idea about the position of a baseball.

FOLLOW-UP PROBLEMS

7.5A How accurately can an umpire know the position of a baseball (mass = 0.142 kg) moving at $100.0 \text{ mi/h} \pm 1.00\%$ ($44.7 \text{ m/s} \pm 1.00\%$)?

7.5B A neutron has a speed of $8 \times 10^7 \text{ m/s} \pm 1\%$. What is the uncertainty in its position? The mass of a neutron is $1.67 \times 10^{-27} \text{ kg}$.

SOME SIMILAR PROBLEMS 7.39(b) and 7.40(b)

› Summary of Section 7.3

- › We no longer view matter and energy as distinct entities.
- › The de Broglie wavelength is based on the idea that an electron (or any object) has wavelike motion. Allowed atomic energy levels are related to allowed wavelengths of the electron's motion.
- › Electrons exhibit diffraction, just as light waves do, and photons exhibit transfer of momentum, just as objects do. This wave-particle duality of matter and energy is observable only on the atomic scale.
- › According to the uncertainty principle, we can never know simultaneously the position and speed of an electron.

7.4

THE QUANTUM-MECHANICAL MODEL OF THE ATOM

Acceptance of the dual nature of matter and energy and of the uncertainty principle culminated in the field of **quantum mechanics**, which examines the wave nature of objects on the atomic scale. In 1926, Erwin Schrödinger (1887–1961) derived an equation that is the basis for the *quantum-mechanical model* of the H atom. The model describes an atom with specific quantities of energy that result from allowed frequencies of its electron's wavelike motion. The electron's position can only be known within a certain probability. Key features of the model are described in the following subsections.

The Atomic Orbital and the Probable Location of the Electron

Two central aspects of the quantum-mechanical model concern the atomic orbital and the electron's probable location.

The Schrödinger Equation and the Atomic Orbital The electron's matter-wave occupies the space near the nucleus and is continuously influenced by it. The **Schrödinger equation** is quite complex, so we will not discuss it in detail here. But the equation includes a mathematical description of the electron's matter-wave in three dimensions in the region of the nucleus; this mathematical description is known as a **wave function**, or **atomic orbital**, referred to as ψ (Greek *psi*, pronounced “sigh”).

An important point to keep in mind throughout this discussion is that an “orbital” in the quantum-mechanical model *bears no resemblance* to an “orbit” in the Bohr model: an *orbit* is an electron's actual path around the nucleus, whereas an *orbital* is a mathematical function that describes the electron's matter-wave but has no physical meaning.

The Probable Location of the Electron While we cannot know *exactly* where the electron is at any moment, we can know where it *probably* is, that is, where it spends most of its time. We get this information by squaring the wave function. Thus, even though ψ has no physical meaning, ψ^2 does and is called the *probability density*, a measure of the probability of finding the electron in some tiny volume of the atom. We depict the electron's probable location in several ways, which we'll look at first for the H atom's *ground state*:

1. *Probability of the electron being in some tiny volume of the atom.* For each energy level, we can create an *electron probability density diagram*, or, more simply, an **electron density diagram**. The value of ψ^2 for a given volume is shown with dots: the greater the density of dots, the higher the probability of finding the electron in that volume. Note that, for the ground state of the H atom,

Figure 7.17 Electron probability density in the ground-state H atom. **A**, In the electron density diagram, the density of dots represents the probability of the electron being within a tiny volume and decreases with distance, r , from the nucleus. **B**, The probability density (ψ^2) decreases with r but does not reach zero (*blow-up circle*). **C**, Counting dots within each layer gives the total probability of the electron being in that layer. **D**, A radial probability distribution plot shows that total electron density peaks *near*, but not *at*, the nucleus. **E**, A 90% probability contour for the ground state of the H atom.

the electron probability density decreases with distance from the nucleus along a line, r (Figure 7.17A). In other words, the probability of finding the electron decreases with increasing distance from the nucleus.

These diagrams are also called **electron cloud depictions** because, if we *could* take a time-exposure photograph of the electron in wavelike motion around the nucleus, it would appear as a “cloud” of positions. The electron cloud is an *imaginary* picture of the electron changing its position rapidly over time; it does *not* mean that an electron is a diffuse cloud of charge.

Figure 7.17B shows a plot of ψ^2 vs. r . Due to the thickness of the printed line, the curve appears to touch the axis; however, in the blow-up circle, we see that *the probability of the electron being far from the nucleus is very small, but not zero*.

2. **Total probability density at some distance from the nucleus.** To find *radial probability distribution*, that is, the *total* probability of finding the electron at some distance r from the nucleus, we first mentally divide the volume around the nucleus into thin, concentric, spherical layers, like the layers of an onion (shown in cross section in Figure 7.17C). Then, we find the *sum of ψ^2 values* in each layer to see which is most likely to contain the electron.

The falloff in probability density with distance has an important effect. Near the nucleus, *the volume of each layer increases faster than its density of dots decreases*. The result of these opposing effects is that the *total* probability peaks in a layer *near*, but not *at*, the nucleus. For example, the total probability in the second layer is higher than in the first, but this result disappears with greater distance. Figure 7.17D shows this result as a **radial probability distribution plot**. ▶

3. **Probability contour and the size of the atom.** How far away from the nucleus can we find the electron? This is the same as asking “How big is the H atom?” Recall from Figure 7.17B that the probability of finding the electron far from the nucleus is not zero. Therefore, we *cannot* assign a definite volume to an atom. However, we can visualize an atom with a shape that defines the volume around an atomic nucleus within which an electron spends a given percentage of its time, typically 90%; such a shape is called a **probability contour** (Figure 7.17E).

As you’ll see later in this section, each atomic orbital has a distinctive radial probability distribution and 90% probability contour.

Quantum Numbers

Part of the mathematical solution of the Schrödinger equation gives three quantum numbers, the principal quantum number, the angular momentum quantum number, and the magnetic quantum number, that describe the size, shape, and orientation in

A Radial Probability Distribution of Apples

An analogy might clarify why the curve in the radial probability distribution plot peaks and then falls off. Picture fallen apples around the base of an apple tree: the density of apples is greatest near the trunk and decreases with distance. Divide the ground under the tree into foot-wide concentric rings and collect the apples within each ring. Apple density is greatest in the first ring, but the area of the second ring is larger, and so it contains a greater *total* number of apples. Farther out near the edge of the tree, rings have more area but lower apple “density,” so the total number of apples decreases. A plot of “number of apples in each ring” vs. “distance from trunk” shows a peak at some distance close to the trunk, as in Figure 7.17D.

 Student Hot Spot

Student data indicate that you may struggle with the concept of the quantum-mechanical model of the atom. Access the eBook to view an additional Learning Resource video on this topic.

space of an atomic orbital. A fourth quantum number, the spin quantum number, describes the behavior of the electron in an atomic orbital.

1. The **principal quantum number (n):**

- n is a positive integer (1, 2, 3, and so forth). It corresponds to the quantum number in Equation 7.5.
- It indicates the relative *size* of the orbital and therefore the relative *distance from the nucleus* of the peak in the radial probability distribution plot. As n increases, the orbital becomes larger and the electron spends more time farther from the nucleus.
- The principal quantum number specifies the atom's energy **level**, or **shell**: *the higher the n value, the higher the energy level*. When the electron occupies an orbital with $n = 1$, the H atom is in its ground state and has its lowest energy. When the electron occupies an orbital with $n = 2$ (first excited state), the atom has more energy.

2. The **angular momentum quantum number (l):**

- l is an integer from 0 to $n - 1$. Thus, the values of l depend on the value of the principal quantum number, n , which sets a limit on the angular momentum quantum number: n limits l . For example,

$$n = 1 \longrightarrow l = 0 \text{ (1 value)}$$

$$n = 2 \longrightarrow l = 0, 1 \text{ (2 values)}$$

$$n = 3 \longrightarrow l = 0, 1, 2 \text{ (3 values)}$$

Thus, the *number* of possible l values equals the value of n .

- The l value gives the atom's **sublevels**, or **subshells**, into which each energy level is divided; each l value is designated by a letter:*

Value of l	Sublevel letter designation
$l = 0$	s
$l = 1$	p
$l = 2$	d
$l = 3$	f

A sublevel is named with its n value and letter designation; for example, the sublevel (subshell) with $n = 2$ and $l = 0$ is called the $2s$ sublevel, while the sublevel with $n = 3$ and $l = 1$ is called the $3p$ sublevel.

- The angular momentum quantum number is related to the *shape* of the orbital; the characteristic shape of each type of orbital will be described later in this section.

3. The **magnetic quantum number (m_l):**

- m_l is an integer from $-l$ through 0 to $+l$. The angular momentum quantum number, l , sets a limit on the magnetic quantum number: l limits m_l .
- The number of m_l values = $2l + 1$ = the number of orbitals for a given l :

$$l = 0 \text{ (} s \text{ sublevel)} \longrightarrow m_l = 0 \text{ (1 value; 1 orbital in the } s \text{ sublevel)}$$

$$l = 1 \text{ (} p \text{ sublevel)} \longrightarrow m_l = -1, 0, +1 \text{ (3 values; 3 orbitals in the } p \text{ sublevel)}$$

$$l = 2 \text{ (} d \text{ sublevel)} \longrightarrow m_l = -2, -1, 0, +1, +2 \text{ (5 values; 5 orbitals in the } d \text{ sublevel)}$$

$$l = 3 \text{ (} f \text{ sublevel)} \longrightarrow m_l = -3, -2, -1, 0, +1, +2, +3 \text{ (7 values; 7 orbitals in the } f \text{ sublevel)}$$

Thus, for a particular value of n , there is only one possible orbital with $l = 0$, but three possible orbitals with $l = 1$, each with its own m_l value.

- The total number of m_l values for a given n value = n^2 = the total number of orbitals in that energy level.
- The magnetic quantum number prescribes the three-dimensional *orientation* of the orbital in the space around the nucleus. For example, each of the three p orbitals with $l = 1$ has its own orientation.

*The letters derive from names of spectroscopic lines: sharp, principal, diffuse, and fundamental. Sublevels with l values greater than 3 are designated by the alphabetical letters after f : $l = 4$ is the g sublevel, $l = 5$ is the h sublevel, and so on.

4. The **spin quantum number** (m_s):

- m_s describes a property of the electron called *spin*.
- It was known that a beam of electrons could be split into two beams in a magnetic field, an observation that can be explained by the idea that an electron behaves like a tiny magnet. A spinning charge generates a tiny magnetic field whose direction depends on the direction of the spin, so we envision the electron spinning on its axis in one of two opposite directions, clockwise or counterclockwise (Figure 7.18).
- Corresponding to the two directions of the electron's magnetic field, m_s has two possible values, $+\frac{1}{2}$ or $-\frac{1}{2}$.

Table 7.2 presents a summary of the four quantum numbers, and Table 7.3 summarizes the relationships between the first three quantum numbers and orbitals for the first four energy levels ($n = 1, 2, 3$, and 4).

Table 7.2 | Summary of Quantum Numbers of Electrons in Atoms

Name	Symbol	Permitted Values	Property
Principal	n	Positive integers (1, 2, 3, ...)	Orbital energy (size)
Angular momentum	l	Integers from 0 to $n - 1$	Orbital shape $l = 0$: s orbital $l = 1$: p orbital $l = 2$: d orbital $l = 3$: f orbital
Magnetic	m_l	Integers from $-l$ to 0 to $+l$	Orbital orientation
Spin	m_s	$+\frac{1}{2}$ or $-\frac{1}{2}$	Direction of e^- spin

Figure 7.18 The direction of electron spin. To account for the splitting of the electron beam, we can imagine the electron as spinning in one of two opposite directions, generating a magnetic field whose direction depends on the direction of spin.

**Student Hot Spot**

Student data indicate that you may struggle with applying quantum numbers. Access the eBook to view an additional Learning Resource video on this topic.

Table 7.3 | Summary of n , l , and m_l Values for the First Four Principal Energy Levels

n	l	Sublevel Designation	m_l	Number of Orbitals in Sublevel ($2l + 1$)	Total Number of Orbitals in Energy Level (n^2)
1	0	1s	0	1	1
2	0	2s	0	1	4
	1	2p	-1, 0, +1	3	
3	0	3s	0	1	9
	1	3p	-1, 0, +1	3	
	2	3d	-2, -1, 0, +1, +2	5	
4	0	4s	0	1	16
	1	4p	-1, 0, +1	3	
	2	4d	-2, -1, 0, +1, +2	5	
	3	4f	-3, -2, -1, 0, +1, +2, +3	7	

SAMPLE PROBLEM 7.6 | Determining Quantum Numbers for an Energy Level

Problem What values of the angular momentum (l) and magnetic (m_l) quantum numbers are allowed for a principal quantum number (n) of 3? What type of orbitals, how many of each type, and how many total orbitals are there in this energy level?

Plan We determine allowable quantum numbers with the rules from the text: l values are integers from 0 to $n - 1$, and m_l values are integers from $-l$ through 0 to $+l$. One m_l value is assigned to each orbital, so the number of m_l values gives the number of orbitals.

Solution Determining l values: for $n = 3$:

$$l = 0 \text{ to } n - 1 = 0 \text{ to } (3 - 1): l = 0, 1, 2.$$

Thus, the $n = 3$ main energy level has s ($l = 0$), p ($l = 1$), and d ($l = 2$) orbitals.

Determining m_l for each l value:

For $l = 0$, $m_l = 0$; one s orbital

For $l = 1$, $m_l = -1, 0, +1$; three p orbitals

For $l = 2$, $m_l = -2, -1, 0, +1, +2$; five d orbitals

There are nine m_l values, so there are nine orbitals with $n = 3$.

Check Table 7.3 shows that we are correct. As we saw, the total number of orbitals for a given n value is n^2 , and for $n = 3$, $n^2 = 9$.

FOLLOW-UP PROBLEMS

7.6A What are the possible l and m_l values for $n = 4$?

7.6B For what value of the principal quantum number n are there five allowed values of l ? What are the allowed m_l values for this n ?

SOME SIMILAR PROBLEMS 7.53 and 7.54

SAMPLE PROBLEM 7.7 | Determining Sublevel Names and Orbital Quantum Numbers

Problem Give the n and l values, name, possible magnetic quantum number(s), and number of orbitals for the sublevel represented by each of the following:

(a) $n = 3$, $l = 2$ (b) $4p$ (c) $n = 2$, $l = 0$ (d) $5f$

Plan For (a) and (c), we name the sublevel (subshell) with the n value and the letter designation of the l value. For (b) and (d), we find the n and l values from the name of the sublevel, converting the letter designation to its l value. From the l value, we find the number of possible m_l values, which equals the number of orbitals in that sublevel.

Solution

	n	l	Sublevel Name	Possible m_l Values	No. of Orbitals
(a)	3	2	$3d$	$-2, -1, 0, +1, +2$	5
(b)	4	1	$4p$	$-1, 0, +1$	3
(c)	2	0	$2s$	0	1
(d)	5	3	$5f$	$-3, -2, -1, 0, +1, +2, +3$	7

Check Check the number of orbitals in each sublevel using

$$\text{No. of orbitals} = \text{no. of } m_l \text{ values} = 2l + 1$$

FOLLOW-UP PROBLEMS

7.7A Give the n and l values, sublevel name, and possible m_l values for the following sublevels:

(a) $n = 2$, $l = 1$ (b) $6d$

7.7B What are the n , l , and possible m_l values for the $4d$ and $6s$ sublevels? How many orbitals are in these sublevels of an atom?

SOME SIMILAR PROBLEMS 7.51, 7.52, and 7.57–7.60

SAMPLE PROBLEM 7.8 | Identifying Incorrect Quantum Numbers

Problem What is wrong with each quantum number designation and/or sublevel name?

	n	l	m_l	Name
(a)	1	1	0	$1p$
(b)	4	3	+1	$4d$
(c)	3	1	-2	$3p$

Plan We recall that the allowed values of n are positive integers (1, 2, 3, etc.), allowed values of l are integers from 0 to $n - 1$, and allowed values of m_l are integers from $-l$ through $+l$.

Solution

- (a) A sublevel with $n = 1$ can only have $l = 0$, not $l = 1$. The correct sublevel name is **1s**.
 (b) A sublevel with $l = 3$ is an **f** sublevel, not a **d** sublevel. The name should be **4f**.
 (c) A sublevel with $l = 1$ can have only -1 , 0 , or $+1$ for m_l , not -2 .

Check Check that l is always less than n , and m_l is always $\geq -l$ and $\leq +l$.

FOLLOW-UP PROBLEMS

7.8A Supply the missing quantum numbers and sublevel names.

n	l	m_l	Name
(a) ?	?	0	4p
(b) 2	1	0	?
(c) 3	2	-2	?
(d) ?	?	?	2s

7.8B What is wrong with each quantum number designation and/or sublevel name?

n	l	m_l	Name
(a) 5	3	4	5f
(b) 2	2	1	2d
(c) 6	1	-1	6s

SOME SIMILAR PROBLEMS 7.61, 7.62, and 7.74

Shapes of Atomic Orbitals

Each sublevel of the H atom consists of a set of orbitals with characteristic shapes. As you'll see in Chapter 8, orbitals for the other atoms have similar shapes.

The s Orbital An orbital with $l = 0$ has a *spherical* shape with the nucleus at its center and is called an **s orbital**. Because a sphere has only one orientation, an **s** orbital has only one m_l value: for any **s** orbital, $m_l = 0$.

1. *The 1s orbital* holds the electron in the H atom's ground state. *The electron probability density is highest at the nucleus*. Figure 7.19A shows this graphically (*top*), and an electron density *relief map* (*inset*) depicts the graph's curve in three dimensions. Note the quarter-section of a three-dimensional electron cloud depiction (*middle*) has the darkest shading at the nucleus. For reasons discussed earlier (see Figure 7.17D and the discussion about the radial probability distribution of apples), the radial probability distribution plot (*bottom*) is highest slightly out from the nucleus. Both plots fall off smoothly with distance from the nucleus.

2. *The 2s orbital* (Figure 7.19B) has two regions of higher electron density. The radial probability distribution (Figure 7.19B, *bottom*) of the more distant region is *higher* than that of the closer one because the sum of Ψ^2 for it is taken over a much larger volume. Between the two regions is a spherical **node**, where the probability of finding the electron drops to zero ($\Psi^2 = 0$ at the node, analogous to zero amplitude of a wave exactly between the peak and trough). Because the 2s orbital is larger than the 1s, an electron in the 2s spends more time farther from the nucleus (in the larger of the two regions) than it does when it occupies the 1s.

3. *The 3s orbital* (Figure 7.19C) has three regions of high electron density and two nodes. Here again, the highest radial probability is at the greatest distance from the nucleus. This pattern of more nodes and higher probability with distance from the nucleus continues with the 4s, 5s, and so forth.

The p Orbital An orbital with $l = 1$ is called a **p orbital** and has two regions (lobes) of high probability, one on *either side* of the nucleus (Figure 7.20). The

Figure 7.19 The 1s, 2s, and 3s orbitals. For each of the s orbitals, a plot of probability density vs. distance (*top*, with the relief map, *inset*, showing the plot in three dimensions) lies above a quarter section of an electron cloud depiction of the 90% probability contour (*middle*), which lies above a radial probability distribution plot (*bottom*). **A**, The 1s orbital. **B**, The 2s orbital. **C**, The 3s orbital.

Figure 7.20 The 2p orbitals. **A**, A radial probability distribution plot of the 2p orbital shows a peak much farther from the nucleus than the peak for the 1s. **B**, Cross section of an electron cloud depiction of the 90% probability contour of the $2p_z$ orbital shows a nodal plane. **C**, An accurate representation of the $2p_z$ probability contour. **D**, The stylized depiction of the $2p_z$ probability contour used in the text. **E**, The three (stylized) 2p orbitals occupy mutually perpendicular regions of space, contributing to the atom's overall spherical shape.

B Cross section of electron cloud depiction, $2p_z$

C Accurate probability contour, $2p_z$

D Stylized probability contour, $2p_z$

E The three 2p orbitals

nucleus lies at the nodal plane of this dumbbell-shaped orbital. Note the following about p orbitals:

- Since the maximum value of l is $n - 1$, only levels with $n = 2$ or higher have a p orbital (there is no $1p$ orbital); the lowest energy p orbital (the one closest to the nucleus) is the $2p$.
- One p orbital consists of *two* lobes, and the electron spends *equal* time in both.
- Similar to the pattern for s orbitals, a $3p$ orbital is larger than a $2p$, a $4p$ is larger than a $3p$, and so forth.
- Unlike s orbitals, p orbitals *have* different spatial orientations. The three possible m_l values of -1 , 0 , and $+1$ refer to three *mutually perpendicular* orientations; that is, while identical in size, shape, and energy, the three p orbitals differ in orientation. We associate p orbitals with the x , y , and z axes: the p_x orbital lies along the x axis, the p_y along the y axis, and the p_z along the z axis. (There is no relationship between a particular axis and a given m_l value.) The p sublevel always consists of three p orbitals.

The d Orbital An orbital with $l = 2$ is called a **d orbital**. There are five possible m_l values for $l = 2$: -2 , -1 , 0 , $+1$, and $+2$. Thus, a d orbital has any one of five orientations, as shown in Figure 7.21; the d sublevel always consists of a set of five d orbitals that are equal in energy. Note the following about d orbitals:

- Four of the five d orbitals have four lobes (a cloverleaf shape) with two mutually perpendicular nodal planes between them and the nucleus at the junction of the lobes (Figure 7.21C). (The orientation of the nodal planes always lies between the orbital lobes.) Three of these orbitals lie in the xy , xz , and yz planes, with their lobes *between* the axes, and are called the d_{xy} , d_{xz} , and d_{yz} orbitals. A fourth, the $d_{x^2-y^2}$ orbital, also lies in the xy plane, but its lobes are *along* the axes.

Figure 7.22 The $4f_{xyz}$ orbital, one of the seven $4f$ orbitals.

Figure 7.23 Energy levels of the H atom.

- The fifth d orbital, the d_{z^2} , has two major lobes *along* the z axis, and a donut-shaped region girdles the center.
- An electron in a d orbital spends equal time in all of its lobes.
- Since the maximum value of l is $n - 1$, only levels with $n = 3$ or higher have a d orbital (there are no $1d$ or $2d$ orbitals); $3d$ is the lowest energy d sublevel.
- Orbitals in the $4d$ sublevel are larger (extend farther from the nucleus) than those in the $3d$, and the $5d$ orbitals are larger still.

The f Orbital and Orbitals with Higher l Values An orbital with $l = 3$ is called an **f orbital** and has a principal quantum number of at least $n = 4$ (there are no $1f$, $2f$, or $3f$ orbitals). For the $l = 3$ sublevel, $m_l = -3, -2, -1, 0, +1, +2, +3$; seven values of m_l indicate seven f orbitals in the sublevel, with seven orientations. Figure 7.22 shows one of the seven f orbitals; each f orbital has a complex, multilobed shape with several nodal planes.

Orbitals with $l = 4$ are g orbitals, but they play no known role in chemical bonding.

The Special Case of Energy Levels in the Hydrogen Atom

With regard to energy levels and sublevels, the H atom is a special case. When an H atom gains energy, its electron occupies an orbital of higher n value, which is (on average) farther from the nucleus. But, because it has just one electron, *hydrogen is the only atom whose energy state depends completely on the principal quantum number, n* . As you'll see in Chapter 8, because of additional nucleus-electron attractions and electron-electron repulsions, the energy states of all other atoms depend on the n and l values of the occupied orbitals. Thus, *for the H atom only*, all four $n = 2$ orbitals (one $2s$ and three $2p$) have the same energy, all nine $n = 3$ orbitals (one $3s$, three $3p$, and five $3d$) have the same energy (Figure 7.23), and so forth.

Summary of Section 7.4

- › The atomic orbital (ψ , wave function) is a mathematical description of the electron's wavelike behavior in an atom. The Schrödinger equation converts each allowed wave function to one of the atom's energy states.
- › The probability density of finding the electron at a particular location is represented by ψ^2 . For a given energy level, an electron density diagram and a radial probability distribution plot show how the electron occupies the space near the nucleus.
- › An atomic orbital is described by three quantum numbers: size (n), shape (l), and orientation (m_l): n limits l to n values, and l limits m_l to $2l + 1$ values.
- › A fourth quantum number (m_s) describes the electron's spin.
- › An energy level has sublevels with the same n value; a sublevel has orbitals with the same n and l values but differing m_l values.
- › A sublevel with $l = 0$ has a spherical (s) orbital; a sublevel with $l = 1$ has three two-lobed (p) orbitals; a sublevel with $l = 2$ has five multilobed (d) orbitals; and a sublevel with $l = 3$ has seven multilobed (f) orbitals.
- › In the special case of the H atom, the energy levels depend only on the n value.

CHAPTER REVIEW GUIDE

Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

Understand These Concepts

1. The wave characteristics of light (the interrelations of frequency, wavelength, and speed; the meaning of amplitude) and the general regions of the electromagnetic spectrum (§7.1)
2. How particles and waves differ in terms of the phenomena of refraction, diffraction, and interference (§7.1)
3. The quantization of energy and how an atom changes its energy by emitting or absorbing quanta of radiation (§7.1)

4. How the photon theory explains the photoelectric effect (§7.1)
5. How Bohr's theory explained the line spectra of the H atom; why the theory is wrong and which ideas we retain (§7.2)
6. The wave-particle duality of matter and energy and the relevant theories and experiments that led to it (de Broglie wavelength, electron diffraction, and photon momentum) (§7.3)
7. The meaning of the uncertainty principle and how uncertainty limits our knowledge of electron properties (§7.3)

- The distinction between ψ (wave function, or atomic orbital) and ψ^2 (probability density) (§7.4)
- How electron density diagrams and radial probability distribution plots depict the electron's location within the atom (§7.4)
- The hierarchy of quantum numbers that describe the size and energy (n), shape (l), and orientation (m_l) of an orbital (§7.4)
- The distinction between energy level (shell), sublevel (subshell), and orbital (§7.4)
- The reason for the spin quantum number and its two possible values (§7.4)
- The shapes of s , p , d , and f orbitals (§7.4)

Master These Skills

- Interconverting wavelength and frequency (SP 7.1)
- Interconverting energy, wavelength, and frequency (SP 7.2)
- Finding the energy change and the wavelength of the photon absorbed or emitted when an H atom changes its energy level (SP 7.3)
- Applying de Broglie's equation to find the wavelength of an electron (SP 7.4)
- Applying the uncertainty principle to see that the location and speed of a particle cannot be determined simultaneously (SP 7.5)
- Determining quantum numbers and sublevel designations (SPs 7.6–7.8)

Key Equations and Relationships

Page numbers appear in parentheses.

- 7.1** Relating the speed of light to its frequency and wavelength (292):

$$c = \lambda \times \nu$$

- 7.2** Relating energy change and frequency (296):

$$\Delta E = h\nu$$

- 7.3** Relating energy change and wavelength (296):

$$\Delta E = \frac{hc}{\lambda}$$

- 7.4** Calculating the wavelength of any line in the H atom spectrum (Rydberg equation) (298):

$$\frac{1}{\lambda} = R \left(\frac{1}{n_1^2} - \frac{1}{n_2^2} \right)$$

where n_1 and n_2 are positive integers and $n_2 > n_1$

- 7.5** Finding the difference between two energy levels in the H atom (302):

$$\Delta E = E_{\text{final}} - E_{\text{initial}} = -2.18 \times 10^{-18} \text{ J} \left(\frac{1}{n_{\text{final}}^2} - \frac{1}{n_{\text{initial}}^2} \right)$$

- 7.6** Calculating the wavelength of any moving particle (de Broglie wavelength) (306):

$$\lambda = \frac{h}{mu}$$

- 7.7** Finding the uncertainty in position or speed of a particle (the uncertainty principle) (309):

$$\Delta x \cdot m \Delta u \geq \frac{h}{4\pi}$$

CHAPTER PRACTICE TEST

The answers to the Practice Test problems are shown below and the full solutions can be found in the e-book.

- A microwave oven emits radiation at a wavelength of 5.00 mm. What is the frequency of this radiation?
(a) $1.67 \times 10^{-8} \text{ s}^{-1}$ (b) $5.64 \times 10^{14} \text{ s}^{-1}$ (c) $1.59 \times 10^2 \text{ s}^{-1}$
(d) $5.64 \times 10^5 \text{ s}^{-1}$ (e) $6.00 \times 10^{10} \text{ s}^{-1}$
- Calculate the wavelength of the line that results when the electron in the hydrogen atom makes a transition from $n = 5$ to $n = 1$.
(a) 54.2 nm (b) 95.0 nm (c) 114 nm
(d) 126 nm (e) 209 nm
- According to the Bohr model for the hydrogen atom, the energy necessary to excite an electron from $n = 6$ to $n = 7$ is _____ the energy necessary to excite an electron from $n = 2$ to $n = 3$.

- (a) less than (b) greater than (c) equal to
(d) either equal to or greater than
(e) either less than or equal to

- 4.** Which of the following orbitals might have an m_l value equal to +2?

- (a) s (b) s and p (c) p and d
(d) s and f (e) d and f

- 5.** Each of the following statements is true except

- (a) The $3s$ orbital has a spherical shape.
(b) The $3d$ orbital set can hold a maximum of 10 electrons.
(c) There are no p orbitals when $n = 1$.
(d) There are seven f orbitals in a set.
(e) The second energy level has one set of d orbitals

CHAPTER PRACTICE TEST (continued)

6. How many orbitals in an atom have the following quantum numbers: $n = 4$, $l = 2$?

- (a) 1 (b) 2 (c) 3 (d) 4 (e) 5 (f) 7

7. Choose the single best answer choice. A photon of light of 450 nm, when compared to light of wavelength 300 nm, has

- (a) a higher frequency. (b) a greater velocity.
(c) lower energy. (d) a shorter wavelength.
(e) two of these (a–d) are true. (f) none of these (a–d) are true.

8. Calculate the energy of *one mole* of photons of ultraviolet radiation with a frequency of 3.00×10^{15} Hz.

- (a) 1.20×10^6 J (b) 5.97×10^{10} J (c) 2.21×10^{-49} J
(d) 4.52×10^9 J (e) 1.99×10^{-18} J

9. Calculate the de Broglie wavelength of a 2.7 g Ping-Pong ball traveling at 12 mi/h.

- (a) 3.6×10^{-21} m (b) 4.6×10^{-32} m (c) 2.0×10^{-35} m
(d) 7.2×10^{-30} m (e) 2.0×10^{-32} m

10. Which of the following combinations (n , l , m_l , m_s) is not allowed?

- (a) 4, 3, 2, $-\frac{1}{2}$ (b) 2, 0, 0, $\frac{1}{2}$ (c) 3, 2, 3, $-\frac{1}{2}$
(d) 5, 1, 0, $\frac{1}{2}$ (e) 4, 2, -2 , $-\frac{1}{2}$

Answers: 1. e; 2. b; 3. a; 4. e; 5. e; 6. e; 7. c; 8. a; 9. b; 10. c

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

$$7.1A \quad \lambda(\text{nm}) = \frac{c}{\nu} = \frac{3.00 \times 10^8 \text{ m/s}}{7.23 \times 10^{14} \text{ s}^{-1}} \times \frac{10^9 \text{ nm}}{1 \text{ m}} = 415 \text{ nm}$$

$$\lambda(\text{\AA}) = 415 \text{ nm} \times \frac{10^{-9} \text{ m}}{1 \text{ nm}} \times \frac{1 \text{\AA}}{10^{-10} \text{ m}} = 4150 \text{\AA}$$

$$7.1B \quad \nu = \frac{c}{\lambda} = \frac{3.00 \times 10^8 \text{ m/s}}{940 \text{ nm}} \times \frac{10^9 \text{ nm}}{1 \text{ m}} = 3.2 \times 10^{14} \text{ s}^{-1}$$

This is infrared radiation.

$$7.2A \quad \lambda = \frac{hc}{E} = \frac{(6.626 \times 10^{-34} \text{ J}\cdot\text{s})(3.00 \times 10^8 \text{ m/s})}{8.2 \times 10^{-19} \text{ J}} \times \frac{10^9 \text{ nm}}{1 \text{ m}} = 240 \text{ nm}$$

$$\nu = \frac{E}{h} = \frac{8.2 \times 10^{-19} \text{ J}}{6.626 \times 10^{-34} \text{ J}\cdot\text{s}} = 1.2 \times 10^{15} \text{ s}^{-1}$$

$$7.2B \quad (a) \text{ UV: } E = hc/\lambda = \frac{(6.626 \times 10^{-34} \text{ J}\cdot\text{s})(3.00 \times 10^8 \text{ m/s})}{1 \times 10^{-8} \text{ m}} = 2 \times 10^{-17} \text{ J}$$

$$(b) \text{ Visible: } E = 4 \times 10^{-19} \text{ J} \quad (c) \text{ IR: } E = 2 \times 10^{-21} \text{ J}$$

As λ increases, E decreases.

7.3A (a) With $n_{\text{final}} = 3$ for an IR photon:

$$\begin{aligned} \Delta E &= -2.18 \times 10^{-18} \text{ J} \left(\frac{1}{n_{\text{final}}^2} - \frac{1}{n_{\text{initial}}^2} \right) \\ &= -2.18 \times 10^{-18} \text{ J} \left(\frac{1}{3^2} - \frac{1}{6^2} \right) \\ &= -2.18 \times 10^{-18} \text{ J} \left(\frac{1}{9} - \frac{1}{36} \right) = -1.82 \times 10^{-19} \text{ J} \end{aligned}$$

(ΔE is negative, since the photon is emitted.)

(b) Use the absolute value of ΔE , since wavelength must have a positive value:

$$\lambda = \frac{hc}{|\Delta E|} = \frac{(6.626 \times 10^{-34} \text{ J}\cdot\text{s})(3.00 \times 10^8 \text{ m/s})}{1.82 \times 10^{-19} \text{ J}} \times \frac{1 \text{\AA}}{10^{-10} \text{ m}} = 1.09 \times 10^4 \text{\AA}$$

7.3B

$$\begin{aligned} (a) \quad \Delta E (\text{J/atom}) &= \frac{hc}{\lambda} \\ &= \frac{(6.626 \times 10^{-34} \text{ J}\cdot\text{s})(3.00 \times 10^8 \text{ m/s})}{410 \text{ nm}} \times \frac{10^9 \text{ nm}}{1 \text{ m}} \\ &= 4.85 \times 10^{-19} \text{ J} = -4.85 \times 10^{-19} \text{ J} \end{aligned}$$

(ΔE is negative, since the photon is emitted.)

$$\begin{aligned} \Delta E (\text{kJ/mol}) &= \frac{-4.85 \times 10^{-19} \text{ J}}{\text{atom}} \times \frac{6.022 \times 10^{23} \text{ atoms}}{\text{mol}} \times \frac{1 \text{ kJ}}{10^3 \text{ J}} \\ &= -292 \text{ kJ/mol} \end{aligned}$$

$$(b) \quad \Delta E = -2.18 \times 10^{-18} \text{ J} \left(\frac{1}{n_{\text{final}}^2} - \frac{1}{n_{\text{initial}}^2} \right)$$

$$\begin{aligned} \frac{1}{n_{\text{final}}^2} &= \frac{\Delta E}{-2.18 \times 10^{-18} \text{ J}} + \frac{1}{n_{\text{initial}}^2} \\ &= \frac{-4.85 \times 10^{-19} \text{ J}}{-2.18 \times 10^{-18} \text{ J}} + \frac{1}{6^2} = 0.25025 \end{aligned}$$

$$\begin{aligned} n_{\text{final}}^2 &= \frac{1}{0.25025} = 4 \\ n_{\text{final}} &= 2 \end{aligned}$$

$$7.4A \quad (a) \quad \lambda = \frac{h}{mu}$$

$$\begin{aligned} u &= \frac{h}{m\lambda} = \frac{6.626 \times 10^{-34} \text{ kg}\cdot\text{m}^2/\text{s}}{(9.11 \times 10^{-31} \text{ kg}) \left(100 \text{ nm} \times \frac{1 \text{ m}}{10^9 \text{ nm}} \right)} \\ &= 7.27 \times 10^3 \text{ m/s} \end{aligned}$$

$$\begin{aligned} (b) \quad u &= \frac{h}{m\lambda} = \frac{6.626 \times 10^{-34} \text{ kg}\cdot\text{m}^2/\text{s}}{(0.0459 \text{ kg}) \left(100. \text{ nm} \times \frac{1 \text{ m}}{10^9 \text{ nm}} \right)} \\ &= 1.44 \times 10^{-25} \text{ m/s} \end{aligned}$$

$$7.4B \quad u (\text{m/s}) = \frac{55 \text{ mi}}{1 \text{ h}} \times \frac{1 \text{ h}}{3600 \text{ s}} \times \frac{1.609 \text{ km}}{1 \text{ mi}} \times \frac{10^3 \text{ m}}{1 \text{ km}} = 25 \text{ m/s}$$

$$\begin{aligned} \lambda &= \frac{h}{mu} = \frac{6.626 \times 10^{-34} \text{ kg}\cdot\text{m}^2/\text{s}}{(0.0397 \text{ kg})(25 \text{ m/s})} \\ &= 6.7 \times 10^{-34} \text{ m} \end{aligned}$$

$$7.5A \quad \Delta u = 1.00\% \text{ of } u = 0.0100 \times 44.7 \text{ m/s} = 0.447 \text{ m/s}$$

$$\Delta x \geq \frac{h}{4\pi m \Delta u} \geq \frac{6.626 \times 10^{-34} \text{ kg}\cdot\text{m}^2/\text{s}}{4\pi (0.142 \text{ kg})(0.447 \text{ m/s})} \geq 8.31 \times 10^{-34} \text{ m}$$

7.5B $\Delta u = 1\%$ of $u = 0.01(8 \times 10^7 \text{ m/s}) = 8 \times 10^5 \text{ m/s}$

$$\Delta x \geq \frac{h}{4\pi m \Delta u} \geq \frac{6.626 \times 10^{-34} \text{ kg} \cdot \text{m}^2/\text{s}}{4\pi (1.67 \times 10^{-27} \text{ kg})(8 \times 10^5 \text{ m/s})} \geq 4 \times 10^{-14} \text{ m}$$

7.6A $n = 4$, so $l = 0, 1, 2, 3$. In addition to the nine m_l values given in Sample Problem 7.6, there are those for $l = 3$: $m_l = -3, -2, -1, 0, +1, +2, +3$.

7.6B For $l = 0, 1, 2, 3, 4$, $n = 5$. In addition to the nine m_l values listed in Sample Problem 7.6 and the seven m_l values listed in Follow-up Problem 7.6A, there are those for $l = 4$: $m_l = -4, -3, -2, -1, 0, +1, +2, +3, +4$.

7.7A (a) $2p$ sublevel; $n = 2$, $l = 1$, $m_l = -1, 0, +1$
 (b) $6d$ sublevel; $n = 6$, $l = 2$, $m_l = -2, -1, 0, +1, +2$

7.7B For $4d$: $n = 4$, $l = 2$, $m_l = -2, -1, 0, +1, +2$; there are five $4d$ orbitals.

For $6s$: $n = 6$, $l = 0$, $m_l = 0$; there is one $6s$ orbital.

7.8A (a) $n = 4$, $l = 1$; (b) name is $2p$; (c) name is $3d$; (d) $n = 2$, $l = 0$, $m_l = 0$

7.8B (a) For $l = 3$, the allowed values for m_l are $-3, -2, -1, 0, +1, +2, +3$, not 4.
 (b) For $n = 2$, $l = 0$ or 1 only, not 2; the sublevel is $2p$, since $m_l = 1$.
 (c) The value $l = 1$ indicates the p sublevel, not the s ; the sublevel name is $6p$.

PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. Comprehensive Problems are based on material from any section or previous chapter.

The Nature of Light

(Sample Problems 7.1 and 7.2)

Concept Review Questions

7.1 In what ways are microwave and ultraviolet radiation the same? In what ways are they different?

7.2 Consider the following types of electromagnetic radiation:

- | | | |
|---------------|-----------------|-----------------|
| (1) Microwave | (2) Ultraviolet | (3) Radio waves |
| (4) Infrared | (5) X-ray | (6) Visible |

- (a) Arrange them in order of increasing wavelength.
 (b) Arrange them in order of increasing frequency.
 (c) Arrange them in order of increasing energy.

7.3 Define each of the following wave phenomena, and give an example of where each occurs: (a) refraction; (b) diffraction; (c) dispersion; (d) interference.

7.4 In the 17th century, Isaac Newton proposed that light was a stream of particles. The wave-particle debate continued for over 250 years until Planck and Einstein presented their ideas. Give two pieces of evidence for the wave model and two for the particle model.

7.5 Portions of electromagnetic waves A, B, and C are represented by the following (not drawn to scale):

Rank them in order of (a) increasing frequency; (b) increasing energy; (c) increasing amplitude. (d) If wave B just barely fails to

cause a current when shining on a metal, is wave A or C more likely to do so? (e) If wave B represents visible radiation, is wave A or C more likely to be IR radiation?

7.6 What new idea about light did Einstein use to explain the photoelectric effect? Why does the photoelectric effect exhibit a threshold frequency but not a time lag?

Skill-Building Exercises (grouped in similar pairs)

7.7 An AM station broadcasts rock music at “950 on your radio dial.” Units for AM frequencies are given in kilohertz (kHz). Find the wavelength of the station’s radio waves in meters (m), nanometers (nm), and angstroms (Å).

7.8 An FM station broadcasts music at 93.5 MHz (megahertz, or 10^6 Hz). Find the wavelength (in m, nm, and Å) of these waves.

7.9 A radio wave has a frequency of 3.8×10^{10} Hz. What is the energy (in J) of one photon of this radiation?

7.10 An x-ray has a wavelength of 1.3 Å. Calculate the energy (in J) of one photon of this radiation.

7.11 Rank these photons in terms of increasing energy: blue ($\lambda = 453$ nm); red ($\lambda = 660$ nm); yellow ($\lambda = 595$ nm).

7.12 Rank these photons in terms of decreasing energy: IR ($\nu = 6.5 \times 10^{13} \text{ s}^{-1}$); microwave ($\nu = 9.8 \times 10^{11} \text{ s}^{-1}$); UV ($\nu = 8.0 \times 10^{15} \text{ s}^{-1}$).

Problems in Context

7.13 Police often monitor traffic with “K-band” radar guns, which operate in the microwave region at 22.235 GHz ($1 \text{ GHz} = 10^9 \text{ Hz}$). Find the wavelength (in nm and Å) of this radiation.

7.14 Covalent bonds in a molecule absorb radiation in the IR region and vibrate at characteristic frequencies.

- (a) The C—O bond absorbs radiation of wavelength 9.6 μm . What frequency (in s^{-1}) corresponds to that wavelength?
 (b) The H—Cl bond has a frequency of vibration of $8.652 \times 10^{13} \text{ Hz}$. What wavelength (in μm) corresponds to that frequency?

7.15 Cobalt-60 is a radioactive isotope used to treat cancers. A gamma ray emitted by this isotope has an energy of 1.33 MeV (million electron volts; $1 \text{ eV} = 1.602 \times 10^{-19} \text{ J}$). What are the frequency (in Hz) and the wavelength (in m) of this gamma ray?

7.16 (a) Ozone formation in the upper atmosphere starts when oxygen molecules absorb UV radiation with wavelengths less than or equal to 242 nm. Find the frequency and energy of the least energetic of these photons. (b) Ozone absorbs radiation with wavelengths in the range 2200–2900 Å, thus protecting organisms from this radiation. Find the frequency and energy of the most energetic of these photons.

Atomic Spectra

(Sample Problem 7.3)

Concept Review Questions

7.17 How is n_1 in the Rydberg equation (Equation 7.4) related to the quantum number n in the Bohr model?

7.18 What key assumption of Bohr's model would a "Solar System" model of the atom violate? What was the theoretical basis for this assumption?

7.19 Distinguish between an absorption spectrum and an emission spectrum. With which did Bohr work?

7.20 Which of these electron transitions correspond to absorption of energy and which to emission?

- (a) $n = 2$ to $n = 4$ (b) $n = 3$ to $n = 1$
(c) $n = 5$ to $n = 2$ (d) $n = 3$ to $n = 4$

7.21 Why couldn't the Bohr model predict spectra for atoms other than hydrogen?

7.22 The H atom and the Be^{3+} ion each have one electron. Would you expect the Bohr model to predict their spectra accurately? Would you expect their spectra to be identical? Explain.

Skill-Building Exercises (grouped in similar pairs)

7.23 Use the Rydberg equation to find the wavelength (in nm) of the photon emitted when an electron in an H atom undergoes a transition from $n = 5$ to $n = 2$.

7.24 Use the Rydberg equation to find the wavelength (in Å) of the photon absorbed when an electron in an H atom undergoes a transition from $n = 1$ to $n = 3$.

7.25 What is the wavelength (in nm) of the least energetic spectral line in the infrared series of the H atom?

7.26 What is the wavelength (in nm) of the least energetic spectral line in the visible series of the H atom?

7.27 Calculate the energy difference (ΔE) for the transition in Problem 7.23 for 1 mol of H atoms.

7.28 Calculate the energy difference (ΔE) for the transition in Problem 7.24 for 1 mol of H atoms.

7.29 Arrange the following H atom electron transitions in order of *increasing* frequency of the photon absorbed or emitted:

- (a) $n = 2$ to $n = 4$ (b) $n = 2$ to $n = 1$
(c) $n = 2$ to $n = 5$ (d) $n = 4$ to $n = 3$

7.30 Arrange the following H atom electron transitions in order of *decreasing* wavelength of the photon absorbed or emitted:

- (a) $n = 2$ to $n = \infty$ (b) $n = 4$ to $n = 20$
(c) $n = 3$ to $n = 10$ (d) $n = 2$ to $n = 1$

7.31 The electron in a ground-state H atom absorbs a photon of wavelength 97.20 nm. To what energy level does it move?

7.32 An electron in the $n = 5$ level of an H atom emits a photon of wavelength 1281 nm. To what energy level does it move?

Problems in Context

7.33 In addition to continuous radiation, fluorescent lamps emit some visible lines from mercury. A prominent line has a wavelength of 436 nm. What is the energy (in J) of one photon of it?

7.34 A Bohr-model representation of the H atom is shown below with several electron transitions depicted by arrows:

- (a) Which transitions are absorptions and which are emissions?
(b) Rank the emissions in terms of increasing energy.
(c) Rank the absorptions in terms of increasing wavelength of light absorbed.

The Wave-Particle Duality of Matter and Energy

(Sample Problems 7.4 and 7.5)

Concept Review Questions

7.35 In what sense is the wave motion of a guitar string analogous to the motion of an electron in an atom?

7.36 What experimental support did de Broglie's concept receive?

7.37 If particles have wavelike motion, why don't we observe that motion in the macroscopic world?

7.38 Why can't we overcome the uncertainty predicted by Heisenberg's principle by building more precise instruments to reduce the error in measurements below the $h/4\pi$ limit?

Skill-Building Exercises (grouped in similar pairs)

7.39 A 232-lb fullback runs 40 yd at 19.8 ± 0.1 mi/h.

- (a) What is the fullback's de Broglie wavelength (in meters)?
(b) What is the uncertainty in the fullback's position?

7.40 An alpha particle (mass = 6.6×10^{-24} g) emitted by a radium isotope travels at $3.4 \times 10^7 \pm 0.1 \times 10^7$ mi/h.

- (a) What is its de Broglie wavelength (in meters)?
(b) What is the uncertainty in its position?

7.41 How fast must a 56.5-g tennis ball travel to have a de Broglie wavelength equal to that of a photon of green light (5400 Å)?

7.42 How fast must a 142-g baseball travel to have a de Broglie wavelength equal to that of an x-ray photon with $\lambda = 100$ pm?

7.43 A sodium flame has a characteristic yellow color due to emission of light of wavelength 589 nm. What is the mass equivalence of one photon with this wavelength ($1 \text{ J} = 1 \text{ kg} \cdot \text{m}^2/\text{s}^2$)?

7.44 A lithium flame has a characteristic red color due to emission of light of wavelength 671 nm. What is the mass equivalence of 1 mol of photons with this wavelength ($1 \text{ J} = 1 \text{ kg} \cdot \text{m}^2/\text{s}^2$)?

The Quantum-Mechanical Model of the Atom

(Sample Problems 7.6 to 7.8)

Concept Review Questions

7.45 What physical meaning is attributed to ψ^2 ?

7.46 What does "electron density in a tiny volume of space" mean?

7.47 Explain the significance of the fact that the peak in the radial probability distribution plot for the $n = 1$ level of an H atom is at 0.529 Å. Is the probability of finding an electron at 0.529 Å from the nucleus greater for the 1s or the 2s orbital?

7.48 What feature of an orbital is related to each of the following?

- (a) Principal quantum number (n)
- (b) Angular momentum quantum number (l)
- (c) Magnetic quantum number (m_l)

7.49 Summarize the rules for the allowable values of the four quantum numbers of an electron in an atom.

7.50 Which of the quantum numbers relate(s) to the electron only?

Skill-Building Exercises (grouped in similar pairs)

7.51 How many orbitals in an atom can have each of the following designations: (a) 1s; (b) 4d; (c) 3p; (d) $n = 3$?

7.52 How many orbitals in an atom can have each of the following designations: (a) 5f; (b) 4p; (c) 5d; (d) $n = 2$?

7.53 Give all possible m_l values for orbitals that have each of the following: (a) $l = 2$; (b) $n = 1$; (c) $n = 4$, $l = 3$.

7.54 Give all possible m_l values for orbitals that have each of the following: (a) $l = 3$; (b) $n = 2$; (c) $n = 6$, $l = 1$.

7.55 Draw 90% probability contours (with axes) for each of the following orbitals: (a) s; (b) p_x .

7.56 Draw 90% probability contours (with axes) for each of the following orbitals: (a) p_z ; (b) d_{xy} .

7.57 For each of the following, give the sublevel designation, the allowable m_l values, and the number of orbitals:

- (a) $n = 4$, $l = 2$
- (b) $n = 5$, $l = 1$
- (c) $n = 6$, $l = 3$

7.58 For each of the following, give the sublevel designation, the allowable m_l values, and the number of orbitals:

- (a) $n = 2$, $l = 0$
- (b) $n = 3$, $l = 2$
- (c) $n = 5$, $l = 1$

7.59 For each of the following sublevels, give the n and l values and the number of orbitals: (a) 5s; (b) 3p; (c) 4f.

7.60 For each of the following sublevels, give the n and l values and the number of orbitals: (a) 6g; (b) 4s; (c) 3d.

7.61 Are the following combinations allowed? If not, show two ways to correct them:

- (a) $n = 2$; $l = 0$; $m_l = -1$
- (b) $n = 4$; $l = 3$; $m_l = -1$
- (c) $n = 3$; $l = 1$; $m_l = 0$
- (d) $n = 5$; $l = 2$; $m_l = +3$

7.62 Are the following combinations allowed? If not, show two ways to correct them:

- (a) $n = 1$; $l = 0$; $m_l = 0$
- (b) $n = 2$; $l = 2$; $m_l = +1$
- (c) $n = 7$; $l = 1$; $m_l = +2$
- (d) $n = 3$; $l = 1$; $m_l = -2$

Comprehensive Problems

7.63 The orange color of carrots and orange peel is due mostly to β -carotene, an organic compound insoluble in water but soluble in benzene and chloroform. Describe an experiment to determine the concentration of β -carotene in the oil from orange peel.

7.64 The quantum-mechanical treatment of the H atom gives the energy, E , of the electron as a function of n :

$$E = -\frac{h^2}{8\pi^2 m_e a_0^2 n^2} \quad (n = 1, 2, 3, \dots)$$

where h is Planck's constant, m_e is the electron's mass, and a_0 is 52.92×10^{-12} m.

(a) Write the expression in the form $E = -(\text{constant})(1/n^2)$, evaluate the constant (in J), and compare it with the corresponding expression from Bohr's theory.

(b) Use the expression from part (a) to find ΔE between $n = 2$ and $n = 3$.

(c) Calculate the wavelength of the photon that corresponds to this energy change.

7.65 The photoelectric effect is illustrated in a plot of the kinetic energies of electrons ejected from the surface of potassium metal or silver metal at different frequencies of incident light.

(a) Why don't the lines begin at the origin? (b) Why don't the lines begin at the same point? (c) From which metal will light of shorter wavelength eject an electron? (d) Why are the slopes equal?

7.66 The optic nerve needs a minimum of 2.0×10^{-17} J of energy to trigger a series of impulses that eventually reach the brain.

(a) How many photons of red light (700. nm) are needed? (b) How many photons of blue light (475 nm)?

7.67 One reason carbon monoxide (CO) is toxic is that it binds to the blood protein hemoglobin more strongly than oxygen does. The bond between hemoglobin and CO absorbs radiation of 1953 cm^{-1} . (The unit is the reciprocal of the wavelength in centimeters.) Calculate the wavelength (in nm and Å) and the frequency (in Hz) of the absorbed radiation.

7.68 A metal ion M^{n+} has a single electron. The highest energy line in its emission spectrum has a frequency of 2.961×10^{16} Hz. Identify the ion.

7.69 Compare the wavelengths of an electron (mass = 9.11×10^{-31} kg) and a proton (mass = 1.67×10^{-27} kg), each having (a) a speed of 3.4×10^6 m/s; (b) a kinetic energy of 2.7×10^{-15} J.

7.70 Five lines in the H atom spectrum have these wavelengths (in Å): (a) 1212.7; (b) 4340.5; (c) 4861.3; (d) 6562.8; (e) 10,938. Three lines result from transitions to $n_{\text{final}} = 2$ (visible series). The other two result from transitions in different series, one with $n_{\text{final}} = 1$ and the other with $n_{\text{final}} = 3$. Identify n_{initial} for each line.

7.71 In his explanation of the threshold frequency in the photoelectric effect, Einstein reasoned that the absorbed photon must have a minimum energy to dislodge an electron from the metal surface. This energy is called the *work function* (ϕ) of the metal. What is the longest wavelength of radiation (in nm) that could cause the photoelectric effect in each of these metals: (a) calcium, $\phi = 4.60 \times 10^{-19}$ J; (b) titanium, $\phi = 6.94 \times 10^{-19}$ J; (c) sodium, $\phi = 4.41 \times 10^{-19}$ J?

7.72 Refractometry is based on the difference in the speed of light through a substance (v) and through a vacuum (c). In the procedure, light of known wavelength passes through a fixed thickness of the substance at a known temperature. The index of refraction equals c/v . Using yellow light ($\lambda = 589 \text{ nm}$) at 20°C ,

for example, the index of refraction of water is 1.33 and that of diamond is 2.42. Calculate the speed of light in (a) water and (b) diamond.

7.73 A laser (light amplification by stimulated emission of radiation) provides nearly monochromatic, high-intensity light. Lasers are used in eye surgery, CD/DVD players, basic research, and many other areas. Some dye lasers can be “tuned” to emit a desired wavelength. Fill in the blanks in the following table of the properties of some common types of lasers:

Type	λ (nm)	ν (s^{-1})	E (J)	Color
He-Ne	632.8	?	?	?
Ar	?	6.148×10^{14}	?	?
Ar-Kr	?	?	3.499×10^{-19}	?
Dye	663.7	?	?	?

7.74 The following combinations are not allowed. If n and m_l are correct, change the l value to create an allowable combination:

- (a) $n = 3$; $l = 0$; $m_l = -1$ (b) $n = 3$; $l = 3$; $m_l = +1$
 (c) $n = 7$; $l = 2$; $m_l = +3$ (d) $n = 4$; $l = 1$; $m_l = -2$

7.75 A ground-state H atom absorbs a photon of wavelength 94.91 nm, and its electron attains a higher energy level. The atom then emits two photons: one of wavelength 1281 nm to reach an intermediate energy level, and a second to return to the ground state.

- (a) What higher level did the electron reach?
 (b) What intermediate level did the electron reach?
 (c) What was the wavelength of the second photon emitted?

7.76 Use the relative size of the $3s$ orbital below to answer the following questions about orbitals A–D.

- (a) Which orbital has the highest value of n ? (b) Which orbital(s) has/have a value of $l = 1$? $l = 2$? (c) How many other orbitals with the same value of n have the same shape as orbital B? Orbital C?
 (d) Which orbital has the highest energy? Lowest energy?

7.77 In the course of developing his model, Bohr arrived at the following formula for the radius of the electron's orbit: $r_n = n^2 h^2 \epsilon_0 / \pi m_e e^2$, where m_e is the electron's mass, e is its charge, and ϵ_0 is a constant related to charge attraction in a vacuum. Given that $m_e = 9.109 \times 10^{-31}$ kg, $e = 1.602 \times 10^{-19}$ C, and $\epsilon_0 = 8.854 \times 10^{-12}$ C²/J·m, calculate the following:

- (a) The radius of the first ($n = 1$) orbit in the H atom
 (b) The radius of the tenth ($n = 10$) orbit in the H atom

7.78 (a) Find the Bohr radius of an electron in the $n = 3$ orbit of an H atom (see Problem 7.77). (b) What is the energy (in J) of the atom in part (a)? (c) What is the energy of an Li^{2+} ion with its electron in the $n = 3$ orbit? (d) Why are the answers to parts (b) and (c) different?

7.79 Enormous numbers of microwave photons are needed to warm macroscopic samples of matter. A portion of soup containing 252 g of water is heated in a microwave oven from 20.°C to

98°C, with radiation of wavelength 1.55×10^{-2} m. How many photons are absorbed by the water in the soup?

7.80 The quantum-mechanical treatment of the hydrogen atom gives this expression for the wave function, ψ , of the $1s$ orbital:

$$\Psi = \frac{1}{\sqrt{\pi}} \left(\frac{1}{a_0} \right)^{3/2} e^{-r/a_0}$$

where r is the distance from the nucleus and a_0 is 52.92 pm. The probability of finding the electron in a tiny volume at distance r from the nucleus is proportional to ψ^2 . The total probability of finding the electron at all points at distance r from the nucleus is proportional to $4\pi r^2 \psi^2$. Calculate the values (to three significant figures) of ψ , ψ^2 , and $4\pi r^2 \psi^2$ to fill in the following table and sketch a plot of each set of values versus r . Compare the latter two plots with those in Figure 7.19A.

r (pm)	Ψ ($\text{pm}^{-3/2}$)	Ψ^2 (pm^{-3})	$4\pi r^2 \Psi^2$ (pm^{-1})

200			

7.81 Lines in one spectral series can overlap lines in another.

- (a) Does the range of wavelengths in the $n_1 = 1$ series for the H atom overlap the range in the $n_1 = 2$ series?
 (b) Does the range in the $n_1 = 3$ series overlap the range in the $n_1 = 4$ series?
 (c) How many lines in the $n_1 = 4$ series lie in the range of the $n_1 = 5$ series?
 (d) What does this overlap imply about the H atom line spectrum at longer wavelengths?

7.82 Photoelectron spectroscopy applies the principle of the photoelectric effect to study orbital energies of atoms and molecules. High-energy radiation (usually UV or x-ray) is absorbed by a sample and an electron is ejected. The orbital energy can be calculated from the known energy of the radiation and the measured energy of the electron lost. The following energy differences were determined for several electron transitions:

$$\begin{aligned} \Delta E_{2 \rightarrow 1} &= 4.098 \times 10^{-17} \text{ J} & \Delta E_{3 \rightarrow 1} &= 4.854 \times 10^{-17} \text{ J} \\ \Delta E_{5 \rightarrow 1} &= 5.242 \times 10^{-17} \text{ J} & \Delta E_{4 \rightarrow 2} &= 1.024 \times 10^{-17} \text{ J} \end{aligned}$$

Calculate ΔE and λ of a photon emitted in the following transitions: (a) level $3 \rightarrow 2$; (b) level $4 \rightarrow 1$; (c) level $5 \rightarrow 4$.

7.83 Horticulturists know that, for many plants, dark green leaves are associated with low light levels and pale green with high levels. (a) Use the photon theory to explain this behavior. (b) What change in leaf composition might account for this difference?

7.84 In order to comply with the requirement that energy be conserved, Einstein showed in the photoelectric effect that the energy of a photon ($h\nu$) absorbed by a metal is the sum of the work function (ϕ), which is the minimum energy needed to dislodge an electron from the metal's surface, and the kinetic energy (E_k) of the electron: $h\nu = \phi + E_k$. When light of wavelength 358.1 nm falls on the surface of potassium metal, the speed (u) of the dislodged electron is 6.40×10^5 m/s.

- (a) What is E_k ($\frac{1}{2} mu^2$) of the dislodged electron?
 (b) What is ϕ (in J) of potassium?

7.85 For any microscope, the size of the smallest observable object is one-half the wavelength of the radiation used. For

example, the smallest object observable with 400-nm light is 2×10^{-7} m. (a) What is the smallest observable object for an electron microscope using electrons moving at 5.5×10^4 m/s? (b) At 3.0×10^7 m/s?

7.86 In fireworks, the heat of the reaction of an oxidizing agent, such as KClO_4 , with an organic compound excites certain salts, which emit specific colors. Strontium salts have an intense emission at 641 nm, and barium salts have one at 493 nm.

(a) What colors do these emissions produce?

(b) What is the energy (in kJ) of these emissions for 5.00 g each of the chloride salts of Sr and Ba? (Assume that all the heat produced is converted to emitted light.)

7.87 Atomic hydrogen produces several series of spectral lines. Each series fits the Rydberg equation with its own particular n_1 value. Calculate the value of n_1 (by trial and error if necessary) that would produce a series of lines in which

(a) The *highest* energy line has a wavelength of 3282 nm.

(b) The *lowest* energy line has a wavelength of 7460 nm.

7.88 Fish-liver oil is a good source of vitamin A, whose concentration is measured spectrometrically at a wavelength of 329 nm.

(a) Suggest a reason for using this wavelength.

(b) In what region of the spectrum does this wavelength lie?

(c) When 0.1232 g of fish-liver oil is dissolved in 500. mL of solvent, the absorbance is 0.724 units. When 1.67×10^{-3} g of vitamin A is dissolved in 250. mL of solvent, the absorbance is 1.018 units. Calculate the vitamin A concentration in the fish-liver oil.

7.89 Many calculators use photocells as their energy source. Find the maximum wavelength needed to remove an electron from silver ($\phi = 7.59 \times 10^{-19}$ J). Is silver a good choice for a photocell that uses visible light? [The concept of the work function (ϕ) is explained in Problem 7.71.]

7.90 In a game of “Clue,” Ms. White is killed in the conservatory. A spectrometer in each room records who is present to help find the murderer. For example, if someone wearing yellow is in a room, light at 580 nm is reflected. The suspects are Col. Mustard, Prof. Plum, Mr. Green, Ms. Peacock (blue), and Ms. Scarlet. At the time of the murder, the spectrometer in the dining room shows a reflection at 520 nm, those in the lounge and the study record lower frequencies, and the one in the library records the shortest possible wavelength. Who killed Ms. White? Explain.

7.91 Technetium (Tc; $Z = 43$) is a synthetic element used as a radioactive tracer in medical studies. A Tc atom emits a beta particle (electron) with a kinetic energy ($E_k = \frac{1}{2}mv^2$) of 4.71×10^{-15} J. What is the de Broglie wavelength of this electron?

7.92 Electric power is measured in watts ($1 \text{ W} = 1 \text{ J/s}$). About 95% of the power output of an incandescent bulb is converted to

heat and 5% to light. If 10% of that light shines on your chemistry textbook, how many photons per second shine on the book from a 75-W bulb? (Assume that the photons have a wavelength of 550 nm.)

7.93 The flame tests for sodium and potassium are based on the emissions at 589 nm and 404 nm, respectively. When both elements are present, the Na^+ emission is so strong that the K^+ emission can be seen only by looking through a cobalt-glass filter.

(a) What are the colors of the Na^+ and K^+ emissions?

(b) What does the cobalt-glass filter do?

(c) Why is KClO_4 used as an oxidizing agent in fireworks rather than NaClO_4 ?

7.94 The net change during photosynthesis involves CO_2 and H_2O forming glucose ($\text{C}_6\text{H}_{12}\text{O}_6$) and O_2 . Chlorophyll absorbs light in the 600–700 nm region.

(a) Write a balanced thermochemical equation for formation of 1.00 mol of glucose.

(b) What is the minimum number of photons with $\lambda = 680.$ nm needed to form 1.00 mol of glucose?

7.95 Only certain transitions are allowed from one energy level to another. In one-electron species, the change in l for an allowed transition is ± 1 . For example, a $3p$ electron can move to a $2s$ orbital but not to a $2p$. Thus, in the UV series, where $n_{\text{final}} = 1$, allowed transitions can start in a p orbital ($l = 1$) of $n = 2$ or higher, not in an s ($l = 0$) or d ($l = 2$) orbital of $n = 2$ or higher. From what orbital do each of the allowed transitions start for the first four emission lines in the visible series ($n_{\text{final}} = 2$)?

7.96 The discharge of phosphate in detergents to the environment has led to imbalances in the life cycle of freshwater lakes. A chemist uses a spectrometric method to measure total phosphate and obtains the following data for known standards:

Absorbance (880 nm)	Concentration (mol/L)
0	0.0×10^{-5}
0.10	2.5×10^{-5}
0.16	3.2×10^{-5}
0.20	4.4×10^{-5}
0.25	5.6×10^{-5}
0.38	8.4×10^{-5}
0.48	10.5×10^{-5}
0.62	13.8×10^{-5}
0.76	17.0×10^{-5}
0.88	19.4×10^{-5}

(a) Draw a curve of absorbance vs. phosphate concentration.

(b) If a sample of lake water has an absorbance of 0.55, what is its phosphate concentration?

As the months in the calendar go by, in most of the U.S. and many other countries, we know that cold winter weather will give way to the warmer weather and new growth of spring, followed by hot temperatures in summer, colorful foliage and cooler temperatures in autumn, and then back to snowy weather to end the year. This recurring pattern is the same each year, so we can predict when the trees will leaf out, and when those same trees will shed their leaves. Elements also exhibit recurring patterns in their properties, patterns that we can use to make predictions about their behavior.

The laboratory work of 19th-century chemists had produced an enormous body of facts about the elements, which became organized into the periodic table:

- *The original periodic table.* In 1870, the Russian chemist Dmitri Mendeleev arranged the 65 elements known at the time into a table and summarized their behavior in the **periodic law**: when arranged by *atomic mass*, the elements exhibit a periodic recurrence of similar properties. Mendeleev left blank spaces in his table and was even able to *predict* the properties of several elements, for example, germanium, that were not discovered until later.
- *The modern periodic table.* Today's periodic table (*in the front of the book*) includes 53 elements not known in 1870 and, most importantly, arranges the elements by *atomic number* (number of protons) *not* atomic mass. This change is based on the work of the British physicist Henry G. J. Moseley, who obtained x-ray spectra of various metals by bombarding the metals with electrons. Moseley found that the largest x-ray peak for each metal was related to the nuclear charge, which increased by 1 for each successive element.

The great test for the new atomic model was to answer one of the central questions in chemistry: *why* do the elements behave as they do? Or, rephrasing to fit the main topic of this chapter, how does the **electron configuration** of an element—the *distribution of electrons within the levels and sublevels of its atoms*—relate to its chemical and physical properties?

IN THIS CHAPTER . . . We explore recurring patterns of electron distributions in atoms to see how they account for the recurring behavior of the elements.

- › We describe a restriction on the number of electrons in an orbital, which allows us to define a unique set of quantum numbers for each electron in an atom of any element.
- › We explore electrostatic effects that lead to splitting of atomic energy levels into sublevels and give rise to the order in which orbitals fill with electrons. This filling order correlates with the order of elements in the periodic table.
- › We examine the reasons for periodic trends in three atomic properties.
- › We see how these trends account for chemical reactivity with regard to metallic and redox behavior, oxide acidity, ion formation, and magnetic behavior.

8.1 CHARACTERISTICS OF MANY-ELECTRON ATOMS

The Schrödinger equation (introduced in Chapter 7) does not give *exact* solutions for the energy levels of *many-electron atoms*, those with more than one electron—that is, all atoms except hydrogen. However, unlike the Bohr model, it gives excellent *approximate* solutions. For many-electron atoms, we have to consider two new ideas: a limit on the number of electrons in an orbital and a splitting of energy levels into sublevels.

The Pauli Exclusion Principle

We can write a set of four quantum numbers for any electron in the ground state of any atom. For example, the lone electron in hydrogen (H; $Z = 1$), which occupies the $1s$ orbital, has the following quantum numbers:

$$\text{H: } n = 1, l = 0, m_l = 0, \text{ and } m_s = +\frac{1}{2} \text{ or } -\frac{1}{2}$$

We cannot assign a definite value for m_s , as we do not know the direction of spin of an electron.

The element after hydrogen is helium (He; $Z = 2$), the first with atoms having more than one electron. The first electron in the He ground state has the same set of quantum numbers as the electron in the H atom, but the second He electron does not. Based on observations of excited states, the Austrian physicist Wolfgang Pauli discovered a principle that determines the arrangement of electrons in orbitals in atoms with more than one electron: ▶

- **Pauli exclusion principle:** *no two electrons in the same atom can have the same four quantum numbers.*

Therefore, the second He electron occupies the same $1s$ orbital as the first but has an opposite spin:

First electron: $n = 1, l = 0, m_l = 0$, and $m_s = +\frac{1}{2}$ (arbitrary assignment of m_s value)

Second electron: $n = 1, l = 0, m_l = 0$, and $m_s = -\frac{1}{2}$

The major consequence of the exclusion principle is that *an atomic orbital can hold a maximum of two electrons, which must have opposing spins*. Two electrons can occupy the same orbital, thus having the same values of n , l and m_l , but each electron must have a unique value of m_s . Since there are only two values of m_s , a third electron cannot be added to that orbital without repeating an m_s value. We say that the $1s$ orbital in He, with its two electrons, is *filled* and that the electrons have *paired spins*.

Electrostatic Effects and Energy-Level Splitting

Electrostatic effects—attraction of opposite charges and repulsion of like charges—play a major role in determining the energy states of many-electron atoms. Unlike the H atom, in which there is only the attraction between nucleus and electron and the energy state is determined *only* by the n value, the energy states of many-electron atoms are also affected by electron-electron repulsions. You'll see shortly how these additional interactions give rise to *the splitting of energy levels into sublevels of differing energies: the energy of an orbital in a many-electron atom depends mostly on its n value (size) and to a lesser extent on its l value (shape)*.

Our first encounter with energy-level splitting occurs with lithium (Li; $Z = 3$). The first two electrons of Li fill its $1s$ orbital, so the third Li electron must go into the $n = 2$ level. But, this level has $2s$ and $2p$ sublevels: which does the third electron enter? For reasons we discuss below, the $2s$ is lower in energy than the $2p$, so the ground state of Li has its third electron in the $2s$.

This energy difference arises from three factors—*nuclear attraction*, *electron repulsions*, and *orbital shape* (i.e., radial probability distribution). Their interplay leads to two phenomena—*shielding* and *penetration*—that occur in all atoms *except*

Baseball Quantum Numbers

The unique set of quantum numbers that describes an electron is analogous to the unique location of a box seat at a baseball game. The stadium (atom) is divided into section (n , level), box (l , sublevel), row (m_l , orbital), and seat (m_s , spin). Only one person (electron) can have this particular set of stadium “quantum numbers.” While many people can occupy the same section, box, and row in the stadium, only one person can occupy a particular seat.

hydrogen. [In the following discussion, keep in mind that more energy is needed to remove an electron from a more stable (lower energy) sublevel than from a less stable (higher energy) sublevel.]

The Effect of Nuclear Charge (Z) on Sublevel Energy Higher charges interact more strongly than lower charges. Therefore, a *higher nuclear charge (more protons in the nucleus) increases nucleus-electron attractions and, thus, lowers sublevel energy (stabilizes the atom)*. We see this effect by comparing the $1s$ sublevel energies of three species with one electron: the H atom ($Z = 1$), the He^+ ion ($Z = 2$), and the Li^{2+} ion ($Z = 3$). Figure 8.1 shows that the $1s$ sublevel in H (one proton attracting one electron) is the least stable (highest energy), so the least energy is needed to remove its electron; and the $1s$ sublevel in Li^{2+} (three protons attracting one electron) is the most stable, so the most energy is needed to remove its electron.

Shielding: The Effect of Electron Repulsions on Sublevel Energy In many-electron atoms, each electron “feels” not only the attraction to the nucleus but also repulsions from other electrons. Repulsions counteract the nuclear attraction somewhat, making each electron easier to remove by, in effect, helping to push it away. We speak of each electron “shielding” the other electrons to some extent from the nuclear charge. **Shielding** (also called *screening*) reduces the full nuclear charge to an **effective nuclear charge (Z_{eff})**, the nuclear charge an electron *actually experiences*, and this lower nuclear charge makes the electron easier to remove.

1. *Shielding by other electrons in a given energy level.* Electrons in the *same* energy level shield each other somewhat. Compare the He atom and He^+ ion: both have a $2+$ nuclear charge, but He has two electrons in the $1s$ sublevel and He^+ has only one (Figure 8.2A). It takes less than half as much energy to remove an electron from He (2372 kJ/mol) than from He^+ (5250 kJ/mol) because the second electron in He repels the first, in effect causing a lower Z_{eff} .

2. *Shielding by electrons in inner energy levels.* Because inner electrons spend nearly all their time *between* the outer electrons and the nucleus, they cause a *much* lower Z_{eff} than do electrons in the same level. We can see this by comparing two atomic systems with the same nucleus, one *with* inner electrons and the other *without*. The ground-state Li atom has two inner ($1s$) electrons and one outer ($2s$) electron, whereas the Li^{2+} ion has only one electron, which occupies the $2s$ orbital in the first excited state (Figure 8.2B). It takes about one-sixth as much energy to remove the $2s$ electron from the Li atom (520 kJ/mol) as it takes to remove it from the Li^{2+} ion (2954 kJ/mol), because the *inner electrons shield very effectively*.

Figure 8.1 The effect of nuclear charge on sublevel energy. Greater nuclear charge lowers sublevel energy (to a more negative number), which makes the electron harder to remove. (The strength of attraction is indicated by the thickness of the black arrows.)

Figure 8.2 Shielding and energy levels. **A**, Within an energy level, each electron shields (red arrows) other electrons from the full nuclear charge (black arrows), so they experience a lower Z_{eff} . **B**, Inner electrons shield outer electrons *much* more effectively than electrons in the same energy level shield each other.

Table 8.1 Values of Z_{eff} for the Sublevels in Potassium ($Z = 19$)

Sublevel	Z_{eff}
1s	18.49
2s	13.01
2p	15.03
3s	8.68
3p	7.73
4s	3.50

Figure 8.3 Penetration and sublevel energy.

Table 8.1 lists the values of Z_{eff} for the electrons in a potassium atom. Although K ($Z = 19$) has a nuclear charge of 19+, all of its electrons have $Z_{\text{eff}} < 19$. The two innermost (1s) electrons have a slightly lower Z_{eff} of 18.49 because they shield each other. The outermost (4s) electron has a significantly lower Z_{eff} of 3.50, as a result of the effective shielding by the 18 inner electrons.

Penetration: The Effect of Orbital Shape on Sublevel Energy To see why the third Li electron occupies the 2s sublevel rather than the 2p, we have to consider orbital shapes, that is, radial probability distributions (Figure 8.3). A 2p orbital (*orange curve*) is slightly closer to the nucleus, on average, than the major portion of the 2s orbital (*blue curve*). But a small portion of the 2s radial probability distribution peaks within the 1s region. Thus, an electron in the 2s orbital spends part of its time “penetrating” very close to the nucleus. **Penetration** has two effects:

- It *increases the nuclear attraction* for a 2s electron over that for a 2p electron.
- It *decreases the shielding* of a 2s electron by the 1s electrons.

Thus, since it takes more energy to remove a 2s electron (520 kJ/mol) than a 2p (341 kJ/mol), the 2s sublevel is lower in energy than the 2p.

Splitting of Levels into Sublevels In general, *penetration and the resulting effects on shielding split an energy level into sublevels of differing energy*. The lower the l value of a sublevel, the more its electrons penetrate closer to the nucleus, and so the greater their attraction to the nucleus. Therefore, *for a given n value, a lower l value indicates a more stable (lower energy) sublevel*:

$$\text{Order of sublevel energies: } s < p < d < f \quad (8.1)$$

Thus, the 2s ($l = 0$) is lower in energy than the 2p ($l = 1$), the 3p ($l = 1$) is lower than the 3d ($l = 2$), and so forth.

Figure 8.4 shows the general energy order of levels (n value) and how they are split into sublevels (l values) of differing energies. (Compare this with the H atom energy levels in Figure 7.23.) Next, we’ll use this energy order to construct a periodic table of ground-state atoms.

› Summary of Section 8.1

- › The Pauli exclusion principle requires each electron in an atom to have a unique set of four quantum numbers; therefore, an orbital can hold no more than two electrons, and their spins must be paired (opposite).
- › Electrostatic interactions determine sublevel energies as follows:
 1. Greater nuclear charge lowers sublevel energy, making electrons harder to remove.
 2. Electron-electron repulsions raise sublevel energy, making electrons easier to remove. Repulsions shield electrons from the full nuclear charge, reducing it to an effective nuclear charge, Z_{eff} . Inner electrons shield outer electrons very effectively.
 3. Penetration makes an electron harder to remove because nuclear attraction increases and shielding decreases. As a result, an energy level is split into sublevels with the energy order $s < p < d < f$.

8.2 THE QUANTUM-MECHANICAL MODEL AND THE PERIODIC TABLE

Quantum mechanics provides the theoretical foundation for the experimentally based periodic table. In this section, we fill the table by determining the *ground-state* electron configuration of each element—the *lowest energy distribution of electrons in the levels and sublevels of its atoms*. Note especially the *recurring pattern in electron configurations, which is the basis for recurring patterns in chemical behavior*.

A useful way to determine electron configurations is based on the **aufbau principle** (German *aufbauen*, “to build up”). We start at the beginning of the periodic table and add one proton to the nucleus and one electron to the *lowest energy sublevel available*. (Of course, one or more neutrons are also added to the nucleus.)

There are two common ways to indicate the distribution of electrons in the sublevels:

- *The electron configuration.* This shorthand notation consists of the principal energy level (n value), the letter designation of the sublevel (l value), and the number of electrons (#) in the sublevel, written as a superscript:

- *The orbital diagram.* An **orbital diagram** consists of a box (or just a line) for each orbital in a given energy level, grouped by sublevel (with nl designation shown beneath), with an arrow representing each electron *and* its spin: the first electron in the orbital will be represented with $\uparrow$ and the second electron will be represented with $\downarrow$. (Throughout the text, orbital occupancy is also indicated by color intensity: no color is empty, pale color is half-filled, and full color is filled.)

Building Up Period 1

Let's begin by applying the aufbau principle to Period 1, whose ground-state elements have only the $n = 1$ level and, thus, only the $1s$ sublevel, which consists of only the $1s$ orbital.

1. *Hydrogen.* The quantum numbers for hydrogen's one electron in the $1s$ orbital are H ($Z = 1$): $n = 1$, $l = 0$, and $m_l = 0$, with an m_s value of either $+\frac{1}{2}$ or $-\frac{1}{2}$. The electron configuration (spoken “one-ess-one”) and orbital diagram are

2. *Helium.* Recall that the first electron in He has the same quantum numbers as the electron in H, but the second He electron has opposing spin (Pauli exclusion principle), giving He ($Z = 2$): $n = 1$, $l = 0$, and $m_l = 0$, with an m_s value of either $+\frac{1}{2}$ or $-\frac{1}{2}$ (if we randomly assign an m_s value of $+\frac{1}{2}$ to the first electron in He, then the second He electron would have an m_s value of $-\frac{1}{2}$). The electron configuration (spoken “one-ess-two,” *not* “one-ess-squared”) and orbital diagram are

Building Up Period 2

The Pauli exclusion principle says an orbital can hold no more than two electrons. Therefore, in He, the $1s$ orbital, the $1s$ sublevel, the $n = 1$ level, and Period 1 are filled. Filling the $n = 2$ level builds up Period 2 and begins with the $2s$ sublevel, which is the next lowest in energy (see Figure 8.4) and consists of only the $2s$ orbital. When the $2s$ sublevel is filled, we proceed to fill the $2p$.

1. *Lithium.* The first two electrons in Li fill the $1s$ sublevel, so the last added Li electron enters the $2s$ sublevel ($n = 2$, $l = 0$, $m_l = 0$). The electron configuration and orbital diagram are

Figure 8.4 Order for filling energy sublevels with electrons. In general, energies of sublevels increase with the principal quantum number n ($1 < 2 < 3$, etc.) and the angular momentum quantum number l ($s < p < d < f$). As n increases, some sublevels overlap; for example, the $4s$ sublevel is lower in energy than the $3d$. (The color of each line indicates the sublevel type.)

Figure 8.5 A vertical orbital diagram for the Li ground state.

(Note that a complete orbital diagram shows all the orbitals for the given n value, whether or not they are occupied.) To save space on a page, orbital diagrams are written horizontally, with the sublevel energy increasing left to right. But Figure 8.5 highlights the energy increase with a vertical orbital diagram for lithium.

2. *Beryllium.* The $2s$ orbital is only half-filled in Li, so the fourth electron of beryllium fills it with the electron's spin paired:

3. *Boron.* The next lowest energy sublevel is the $2p$. A p sublevel has $l = 1$, so the m_l (orientation) value can be -1 , 0 , or $+1$. The three orbitals in the $2p$ sublevel have equal energy (same n and l values), which means that the fifth electron of boron can go into any one of the $2p$ orbitals ($m_l = -1$, 0 , or $+1$).

4. *Carbon.* To minimize electron-electron repulsions, the sixth electron of carbon enters one of the unoccupied $2p$ orbitals rather than the $2p$ orbital that already holds one electron. Experiment shows that the spin of this electron is parallel to (the same as) the spin of the other $2p$ electron, a fact that can be stated as follows:

- **Hund's rule:** when orbitals of equal energy are available, the electron configuration of lowest energy has the maximum number of unpaired electrons with parallel spins.

Another way to express this is that no electrons are paired in a set of orbitals of equal energy until every orbital in the set has one electron. Thus, the sixth electron of carbon has the same n , l , and m_s value as the other $2p$ electron, but a different m_l value.

5. *Nitrogen.* Based on Hund's rule, nitrogen's seventh electron enters the last empty $2p$ orbital, with its spin parallel to the other two.

6. *Oxygen.* The eighth electron in oxygen must enter one of the three half-filled $2p$ orbitals and "pair up" with (oppose the spin of) the electron already there. We place the electron in the first half-filled $2p$ orbital:

7. *Fluorine.* Fluorine's ninth electron enters the next of the two remaining half-filled $2p$ orbitals.

8. *Neon.* Only one half-filled $2p$ orbital remains, so the tenth electron of neon occupies it and the $n = 2$ level is filled.

Figure 8.6 Depicting orbital occupancy for the first 10 elements. In addition to atomic number, atomic symbol, and ground-state electron configuration, each box shows the probability contours of the atom's orbitals. Orbital occupancy is indicated by lighter shading for half-filled (one e^-) orbitals and darker shading for filled (two e^-) orbitals.

With our attention on these notations, it's easy to forget that atoms are real objects and electrons occupy volumes with specific shapes and orientations. Figure 8.6 shows orbital contours for the first 10 elements arranged in periodic table format.

Building Up Period 3

The Period 3 elements, Na through Ar, lie directly under the Period 2 elements, Li through Ne. That is, even though the $n = 3$ level splits into $3s$, $3p$, and $3d$ sublevels, Period 3 fills only $3s$ and $3p$; as you'll see shortly, the $3d$ is filled in Period 4. Table 8.2 introduces two ways to present electron distributions more concisely:

- *Partial orbital diagrams* show only the sublevels being filled, here the $3s$ and $3p$.
- *Condensed electron configurations (rightmost column)* have the element symbol of the noble gas from the previous row in brackets, to represent its configuration,

Atomic Number	Element	Partial Orbital Diagram (3s and 3p Sublevels Only)	Full Electron Configuration	Condensed Electron Configuration
11	Na	$3s$ 	$[1s^2 2s^2 2p^6] 3s^1$	$[\text{Ne}] 3s^1$
12	Mg	$3s$ 	$[1s^2 2s^2 2p^6] 3s^2$	$[\text{Ne}] 3s^2$
13	Al	$3s$ 	$[1s^2 2s^2 2p^6] 3s^2 3p^1$	$[\text{Ne}] 3s^2 3p^1$
14	Si	$3s$ 	$[1s^2 2s^2 2p^6] 3s^2 3p^2$	$[\text{Ne}] 3s^2 3p^2$
15	P	$3s$ 	$[1s^2 2s^2 2p^6] 3s^2 3p^3$	$[\text{Ne}] 3s^2 3p^3$
16	S	$3s$ 	$[1s^2 2s^2 2p^6] 3s^2 3p^4$	$[\text{Ne}] 3s^2 3p^4$
17	Cl	$3s$ 	$[1s^2 2s^2 2p^6] 3s^2 3p^5$	$[\text{Ne}] 3s^2 3p^5$
18	Ar	$3s$ 	$[1s^2 2s^2 2p^6] 3s^2 3p^6$	$[\text{Ne}] 3s^2 3p^6$

*Colored type indicates the sublevel to which the last electron has been added.

followed by the electron configuration of filled inner sublevels and the energy level being filled. For example, the condensed electron configuration of chlorine is $[\text{Ne}] 3s^2 3p^5$, where $[\text{Ne}]$ stands for $1s^2 2s^2 2p^6$.

In Na (the second alkali metal) and Mg (the second alkaline earth metal), electrons are added to the $3s$ sublevel, which contains only the $3s$ orbital and is the next lowest energy sublevel after the $2p$, which is now full; this is directly comparable to the filling of the $2s$ sublevel in Li and Be in Period 2. Then, in the same way as the $2p$ orbitals of B, C, and N in Period 2 are half-filled, the last electrons added to Al, Si, and P in Period 3 half-fill successive $3p$ orbitals with spins parallel (Hund's rule). The last electrons added to S, Cl, and Ar then successively pair up to fill those $3p$ orbitals, and thus the $3p$ sublevel.

Building Up Period 4: The First Transition Series

Period 4 contains the first series of **transition elements**, those in which d orbitals are being filled. Let's examine three factors that affect the filling pattern in a period with a transition series; we focus on Period 4, but similar effects occur in Periods 5–7.

1. *Effects of shielding and penetration on sublevel energy.* The $3d$ sublevel is filled in Period 4, but the $4s$ sublevel is filled first. This switch in filling order is due to shielding and penetration effects:

- Based on the $3d$ radial probability distribution (see Figure 7.21), a $3d$ electron spends most of the time outside the filled inner $n = 1$ and $n = 2$ levels, so it is shielded very effectively from the nuclear charge.
- The outermost $4s$ electron, however, is subject to a greater attraction to the nucleus because it penetrates close to the nucleus part of the time (Figure 8.7).
- As a result, the $4s$ orbital is slightly lower in energy than the $3d$ and fills first.

In any period, the ns sublevel fills before the $(n - 1)d$ sublevel. Other variations in the filling pattern occur at higher values of n because sublevel energies become very close together (see Figure 8.4).

Figure 8.7 Effect of penetration on $3d$ vs. $4s$ sublevel energy.

2. *Filling the $4s$ and $3d$ sublevels.* Table 8.3 shows the partial orbital diagrams and full and condensed electron configurations for the 18 elements in Period 4. The first two elements, K and Ca, are the next alkali and alkaline earth metals, respectively; the last electron of K half-fills and that of Ca fills the $4s$ sublevel. The last electron of scandium (Sc; $Z = 21$), the first transition element, occupies any one of the five $3d$ orbitals because they are equal in energy; Sc has the electron configuration $[\text{Ar}] 4s^2 3d^1$. Filling of the $3d$ orbitals proceeds one electron at a time, as with the p orbitals, except in two cases, chromium (Cr; $Z = 24$) and copper (Cu; $Z = 29$), discussed next.

3. *Stability of half-filled and filled sublevels.* When we examine the electron configurations of the Period 4 transition elements, two exceptions stand out. The last electron of Cr does not enter a fourth empty d orbital to give $[\text{Ar}] 4s^2 3d^4$ as expected; instead, Cr has one electron in the $4s$ sublevel and five in the $3d$ sublevel, making both sublevels half-filled: $[\text{Ar}] 4s^1 3d^5$. In the next element, manganese (Mn; $Z = 25$), the $4s$ sublevel is filled again ($[\text{Ar}] 4s^2 3d^5$).

Because it follows nickel (Ni; $[\text{Ar}] 4s^2 3d^8$), copper would be expected to have the configuration $[\text{Ar}] 4s^2 3d^9$. Instead, the $4s$ sublevel of Cu is *half-filled* with 1 electron, and the $3d$ sublevel is *filled* with 10. From these two exceptions, Cr and Cu, we conclude that *half-filled and filled sublevels are unexpectedly stable (low in energy)*; we see this pattern with many other elements.

With zinc (Zn; $Z = 30$), the $4s$ sublevel is filled ($[\text{Ar}] 4s^2 3d^{10}$), and the first transition series ends. The $4p$ sublevel is filled in the next six elements, and Period 4 ends with the noble gas krypton (Kr; $Z = 36$).

Table 8.3 | Partial Orbital Diagrams and Electron Configurations* for the Elements in Period 4

*Colored type indicates sublevel(s) whose occupancy changes when the last electron is added.

General Principles of Electron Configurations

Figure 8.8 shows the partial (just the highest energy sublevels being filled) ground-state electron configurations of the 118 known elements. Let's highlight some key relationships among them.

Orbital Filling Order The elements are “built up” by filling levels and sublevels in the order of increasing energy shown in Figure 8.4. But memorizing that order is unnecessary, because it is reflected in the periodic table: reading the table from left to right, like words on a page, gives the energy order of levels and sublevels (Figure 8.9). Note the following:

- The period number is the n value of the outermost s and p sublevels.
- The period number $- 1$ is the n value of the outermost d sublevel (Periods 4–7).
- The period number $- 2$ is the n value of the outermost f sublevel (Periods 6–7).

Categories of Electrons Atoms have three categories of electrons; the electron configurations of phosphorus (P), manganese (Mn), and tellurium (Te) will be used to show examples (in color) of each category:

Figure 8.8 A periodic table of partial ground-state electron configurations.

1. **Inner (core) electrons** are those an atom has in common with the previous noble gas and any *completed* transition series. They fill all the *lower energy levels* of an atom.

10 inner electrons

18 inner electrons

46 inner electrons

2. **Outer electrons** are those in the *highest energy level* (highest n value). They spend most of their time farthest from the nucleus.

5 outer electrons

2 outer electrons

6 outer electrons

Among the main-group elements, the group number indicates the number of outer electrons; Group 1 and Group 2 elements have 1 and 2 outer electrons, respectively, Group 13 elements have 3 outer electrons, Group 14 elements have 4 outer electrons, and so forth.

3. **Valence electrons** are those involved in forming compounds:

- For main-group elements, the *valence electrons are the outer electrons*.
- For transition elements, in addition to the outer ns electrons, the $(n - 1)d$ electrons are also valence electrons, though the metals Fe ($Z = 26$) through Zn ($Z = 30$) may use only a few, if any, of their d electrons in bonding.

5 valence electrons

7 valence electrons

6 valence electrons

Figure 8.9 Orbital filling and the periodic table. This form of the periodic table shows the sublevel blocks. Pale green inset: A summary of the sublevel filling order.

Intervening Series: Transition and Inner Transition Elements

As Figure 8.9 shows, the d block and f block occur between the main-group s and p blocks.

1. **Transition series.** Periods 4, 5, 6, and 7 incorporate the $3d$, $4d$, $5d$, and $6d$ sublevels, respectively. As you've seen, the general pattern is that the $(n - 1)d$ sublevel is filled between the ns and np sublevels. Thus, in Period 5, the filling order is $5s$, then $4d$, and then $5p$.

2. **Inner transition series.** Period 6 contains the first of two series of **inner transition elements**, those in which f orbitals are being filled (see Figure 8.9). The f orbitals have $l = 3$, so the possible m_l values are -3 , -2 , -1 , 0 , $+1$, $+2$, and $+3$; that is, there are seven f orbitals, for a total of 14 elements in *each* of the two inner transition series:

- The Period 6 inner transition series, called the **lanthanides** (or **rare earths**), occurs after lanthanum (La; $Z = 57$), and in it the $4f$ orbitals are filled.
- The Period 7 inner transition series, called the **actinides**, occurs after actinium (Ac; $Z = 89$), and in it the $5f$ orbitals are filled.

Thus, in Periods 6 and 7, the filling sequence is ns , first of the $(n - 1)d$, all $(n - 2)f$, remainder of the $(n - 1)d$, and np . Period 6 ends with the $6p$ sublevel, and Period 7 ends with the $7p$ sublevel.

3. **Irregular filling patterns.** Irregularities in the filling pattern, such as those for Cr and Cu in Period 4, occur in the d and f blocks because the sublevel energies in these larger atoms differ very little. Even though occasional deviations occur in the d block, the sum of ns electrons and $(n - 1)d$ electrons always equals the group number. For instance, despite variations in Group 6—Cr, Mo, W, and Sg—the sum of ns and $(n - 1)d$ electrons is 6; for Group 10—Ni, Pd, Pt, and Ds—the sum is 10.

In summary, we will use the following guidelines to write the electron configuration of any element, keeping in mind that deviations do occur:

- Place each successive electron in the next available orbital of lowest possible energy; the order of filling is shown in Figures 8.4 and 8.9.
- Each orbital holds a maximum of 2 electrons:
 - The one s orbital in a sublevel can hold 2 electrons (s^2).
 - The three orbitals in a p sublevel can hold a total of 6 electrons (p^6).
 - The five orbitals in a d sublevel can hold a total of 10 electrons (d^{10}).
 - The seven orbitals in an f sublevel can hold a total of 14 electrons (f^{14}).
- Electrons will not pair in a set of equal energy orbitals if an empty orbital is available (Hund's rule).

Similar Electron Configurations Within Groups

As shown in Figure 8.8, there is similarity in outer electron configuration within a group of elements. Among the main-group elements—the s -block and p -block elements—outer electron configurations within a group are identical. Some variations do occur in the transition elements (d block) and inner transition elements (f block). One of the central

Figure 8.10 Similar reactivities in a group. **A**, Potassium reacting with water. **B**, Chlorine reacting with potassium. Source: Stephen Frisch/McGraw Hill

points in chemistry is that *similar outer electron configurations correlate with similar chemical behavior*. Here are examples from three of the groups:

- The Group 1 elements, Li, Na, K, Rb, Cs, and Fr, have the outer electron configuration ns^1 (where n is the quantum number of the highest energy level). All are highly reactive metals whose atoms lose the outer electron when they form ionic compounds with nonmetals, and all react vigorously with water to displace H_2 (Figure 8.10A).
- The Group 17 elements, F, Cl, Br, I, and At, have the outer electron configuration ns^2np^5 . All are reactive nonmetals that occur as diatomic molecules (X_2), and all form ionic compounds with metals (KX , MgX_2) in which their ionic charge is 1– (Figure 8.10B), covalent compounds with hydrogen (HX) that yield acidic solutions in water, and covalent compounds with carbon (CX_4).
- In Group 18, He has the electron configuration ns^2 , and all the other elements in the group have the outer configuration ns^2np^6 . Due to their *filled* energy levels, all the members are very unreactive monatomic gases.

To summarize the major connection between quantum mechanics and chemical periodicity, *sublevels are filled in order of increasing energy, which leads to outer electron configurations that recur periodically, leading to chemical properties that recur periodically*.

Student Hot Spot

Student data indicate that you may struggle with writing electron configurations. Access the eBook to view an additional Learning Resource video on this topic.

SAMPLE PROBLEM 8.1

Determining Electron Configurations

Problem Using only the periodic table (not Figure 8.8 or Table 8.3) and assuming a regular filling pattern, give the full and condensed electron configurations, partial orbital diagram showing valence electrons only, the number of unpaired electrons, and number of inner, outer, and valence electrons for the following elements:

(a) Potassium (K; $Z = 19$) (b) Technetium (Tc; $Z = 43$) (c) Lead (Pb; $Z = 82$)

Plan The atomic number tells us the number of electrons, and the periodic table shows the order for filling sublevels. In the partial orbital diagrams, we include all electrons added after the previous noble gas *except* those in *filled* inner sublevels. The number of inner electrons is the sum of those in the previous noble gas and in filled d and f sublevels. The outer electrons are those in the orbitals with the highest n value. For main-group elements, the outer electrons are also valence electrons; for transition elements, the valence electrons are outer ns electrons and $(n - 1)d$ electrons.

Solution (a) For K ($Z = 19$), the full electron configuration is $1s^22s^22p^63s^23p^64s^1$. The condensed configuration is $[Ar] 4s^1$.

The partial orbital diagram showing valence electrons is

There is **one unpaired electron**. The inner electrons in K are those in the [Ar] part of the condensed electron configuration; there are **18 inner electrons**. There is **1 outer electron and 1 valence electron** (the $4s^1$ electron).

(b) For Tc ($Z = 43$), assuming the expected pattern, the full electron configuration is $1s^2 2s^2 2p^6 3s^2 3p^6 4s^2 3d^{10} 4p^6 5s^2 4d^5$.

The condensed electron configuration is [Kr] $5s^2 4d^5$.

The partial orbital diagram showing valence electrons is

There are **five unpaired electrons**. The inner electrons in Tc are those in the [Kr] part of the condensed electron configuration; there are **36 inner electrons**. There are **2 outer electrons** (the $5s^2$ electrons) and **7 valence electrons** ($5s^2 4d^5$ electrons).

(c) For Pb ($Z = 82$), the full electron configuration is $1s^2 2s^2 2p^6 3s^2 3p^6 4s^2 3d^{10} 4p^6 5s^2 4d^{10} 5p^6 6s^2 4f^{14} 5d^{10} 6p^2$.

The condensed electron configuration is [Xe] $6s^2 4f^{14} 5d^{10} 6p^2$.

The partial orbital diagram showing valence electrons (no filled inner sublevels) is

There are **two unpaired electrons**. The inner electrons in Pb are the 54 electrons represented by [Xe] plus the 14 electrons in the filled $4f$ sublevel plus the 10 electrons in the filled $5d$ sublevel, for a total of **78 inner electrons**. There are **4 outer electrons and 4 valence electrons** (the $6s^2$ and $6p^2$ electrons).

Check Be sure that the sum of the superscripts (numbers of electrons) in the full electron configuration equals the atomic number and that the number of *valence* electrons in the condensed configuration equals the number of electrons in the partial orbital diagram.

FOLLOW-UP PROBLEMS

Brief Solutions for all Follow-up Problems appear at the end of the chapter.

8.1A Without referring to Table 8.3 or Figure 8.8, give full and condensed electron configurations, partial orbital diagrams showing valence electrons only, the number of unpaired electrons, and number of inner, outer, and valence electrons for the following elements:

(a) Ni ($Z = 28$) (b) Sr ($Z = 38$) (c) Po ($Z = 84$)

8.1B From each partial orbital diagram (valence electrons only), identify the element and give its full and condensed electron configuration and the number of inner, outer, and valence electrons. Use only the periodic table, without referring to Table 8.3 or Figure 8.8.

SOME SIMILAR PROBLEMS 8.21–8.36

Summary of Section 8.2

- › In applying the aufbau principle, one electron is added to an atom of each successive element in accord with the Pauli exclusion principle (no two electrons can have the same set of quantum numbers) and Hund's rule (orbitals of equal energy become half-filled, with electron spins parallel, before any pairing of spins occurs).

Figure 8.11 Defining atomic size. **A**, The metallic radius of aluminum. **B**, The covalent radius of chlorine. **C**, Known covalent radii and distances between nuclei can be used to find unknown radii.

- › For the main-group elements, valence electrons (those involved in reactions) are in the outer (highest energy) level only. For transition elements, $(n - 1)d$ electrons are also considered valence electrons.
- › Because of shielding of d electrons by electrons in inner sublevels and penetration by the ns electron, the $(n - 1)d$ sublevel fills after the ns and before the np sublevels.
- › In Periods 6 and 7, $(n - 2)f$ orbitals fill between the first and second $(n - 1)d$ orbitals.
- › The elements of a group have similar outer electron configurations and similar chemical behavior.

8.3 TRENDS IN THREE ATOMIC PROPERTIES

In this section, we focus on three atomic properties directly influenced by electron configuration and effective nuclear charge: atomic size, ionization energy, and electron affinity. Most importantly, these properties are *periodic*, which means they generally exhibit consistent changes, or *trends*, within a group or period.

Trends in Atomic Size

Recall from Chapter 7 that we often represent atoms with spherical contours in which the electrons spend 90% of their time. We *define atomic size* (the extent of the spherical contour for a given atom) in terms of how closely one atom lies next to another. But, in practice, as we discuss in Chapter 12, we measure the distance between atomic nuclei in a sample of an element and divide that distance in half. Because atoms do not have hard surfaces, the size of an atom in a given compound depends somewhat on the atoms near it. In other words, *atomic size varies slightly from substance to substance*.

Figure 8.11 shows two common definitions of atomic size:

1. **Metallic radius.** Used mostly for *metals*, it is one-half the shortest distance between nuclei of adjacent, individual atoms in a crystal of the element (see Figure 8.11A).
2. **Covalent radius.** Used for elements occurring as molecules, mostly *nonmetals*, it is one-half the shortest distance between nuclei of bonded atoms (see Figure 8.11B).

Radii measured for some elements are used to determine the radii of other elements from the distances between the atoms in compounds. For instance, in a carbon-chlorine compound, the distance between nuclei in a C—Cl bond is 177 pm. Using the known covalent radius of Cl (100 pm), we find the covalent radius of C (177 pm – 100 pm = 77 pm) (see Figure 8.11C).

Periodicity of Atomic Size Figure 8.12 shows the atomic radii of the main-group elements and most of the transition elements. Atomic size varies within both groups and periods as a result of two opposing influences:

1. *Changes in n .* As the principal quantum number (n) increases, the probability that outer electrons spend most of their time farther from the nucleus increases as well; thus, *atomic size increases*.
2. *Changes in Z_{eff} .* As the effective nuclear charge (Z_{eff}) increases, outer electrons are pulled closer to the nucleus; thus, *atomic size decreases*.

The net effect of these influences depends on how effectively the inner electrons shield the increasing nuclear charge:

1. *Down a group, n dominates.* As we move down a main group, each member has *one more level of inner electrons that shield the outer electrons very effectively*. Even

Figure 8.12 Atomic radii of the main-group and transition elements. Atomic radii (in picometers) are shown for the main-group elements (*tan*) and the transition elements (*blue*). (Values for the noble gases are calculated.)

though additional protons do moderately increase Z_{eff} for the outer electrons, the atoms get larger as a result of the increasing n value:

*Atomic radius generally **increases** down a group.*

2. *Across a period, Z_{eff} dominates.* Across a period from left to right, electrons are added to the *same* outer level, so the shielding by inner electrons does not change. Despite greater electron repulsions, outer electrons shield each other only slightly, so Z_{eff} rises significantly, and the outer electrons are pulled closer to the nucleus:

*Atomic radius generally **decreases** across a period (left to right).*

Figure 8.13 shows the variation in atomic size with atomic number. Note the up-and-down pattern as size drops across a period to the noble gas (*purple*) and then leaps up to the alkali metal (*brown*) that begins the next period. Also note the deviations from the smooth size decrease in each transition (*blue*) and inner transition (*green*) series. The reasons for these deviations will be discussed in Chapter 23.

Figure 8.13 Periodicity of atomic radius.**SAMPLE PROBLEM 8.2** | Ranking Elements by Atomic Size

Problem Using only the periodic table (not Figure 8.12), rank each set of main-group elements in order of *decreasing* atomic size:

- (a) Ca, Mg, Sr (b) K, Ga, Ca (c) Br, Rb, Kr (d) Sr, Ca, Rb

Plan To rank the elements by atomic size, we find them in the periodic table. Size increases down a group and decreases across a period.

Solution (a) $\text{Sr} > \text{Ca} > \text{Mg}$. These three elements are in Group 2, and size increases down the group.

(b) $\text{K} > \text{Ca} > \text{Ga}$. These three elements are in Period 4, and size decreases across a period.

(c) $\text{Rb} > \text{Br} > \text{Kr}$. Rb is largest because it has one more energy level (Period 5) and is farthest to the left. Kr is smaller than Br because Kr is farther to the right in Period 4.

(d) $\text{Rb} > \text{Sr} > \text{Ca}$. Ca is smallest because it has one fewer energy level. Sr is smaller than Rb because it is farther to the right.

Check From Figure 8.12, we see that the rankings are correct.

FOLLOW-UP PROBLEMS

8.2A Using only the periodic table, rank the elements in each set in order of *increasing* size: (a) Se, Br, Cl; (b) I, Xe, Ba.

8.2B Using only the periodic table, rank the elements in each set in order of *decreasing* size: (a) As, Cs, S; (b) F, P, K.

SOME SIMILAR PROBLEMS 8.50 and 8.51

Trends in Ionization Energy

The **ionization energy (IE)** is the energy required for the *complete removal* of 1 mol of electrons from 1 mol of gaseous atoms or ions. Pulling an electron away from a nucleus *requires* energy to overcome electrostatic attraction between the negatively charged electron and the positively charged protons in the nucleus. Because energy flows *into* the system, the ionization energy is always positive (like ΔH of an endothermic reaction).

Figure 8.14 Periodicity of first ionization energy (IE₁). This trend is the *inverse* of the trend in atomic size (see Figure 8.13).

Many-electron atoms can lose more than one electron. The *first* ionization energy (IE₁) removes an outermost electron (one in the highest energy sublevel) from a gaseous atom:

The ionization energy is a key factor in an element's reactivity:

- Atoms with a low IE tend to form cations during reactions.
- Atoms with a high IE (except the noble gases) tend to form anions.

Periodicity of First Ionization Energy Figure 8.14 shows the variation in first ionization energy with atomic number. This up-and-down pattern—IE₁ rising across a period to the noble gas (purple) and then dropping down to the next alkali metal (brown)—is the *inverse* of the variation in atomic size (see Figure 8.13):

- As size decreases, it takes more energy to remove an electron because the nucleus is closer to the electron, so IE₁ increases.

Let's examine the group and period trends and their exceptions:

1. *Down a group.* As we move down a main group, the *n* value increases, so atomic size does as well. As the distance from nucleus to outer electron increases, the attraction between nucleus and outer electron lessens, so the electron is easier to remove (Figure 8.15):

*Ionization energy generally **decreases** down a group.*

The only significant exception occurs in Group 13: IE₁ decreases from boron (B) to aluminum (Al), but not for the rest of the group. Filling the transition series in Periods 4, 5, and 6 causes a much higher *Z*_{eff} and an unusually small change in size, so outer electrons in the larger Group 13 members are held tighter.

2. *Across a period.* As we move left to right across a period, *Z*_{eff} increases and atomic size decreases. The attraction between nucleus and outer electron increases, so the electron is harder to remove:

*Ionization energy generally **increases** across a period.*

Figure 8.15 First ionization energies of the main-group elements.

There are two exceptions to the otherwise smooth increase in IE_1 across periods:

- In Periods 2 and 3, there are dips in IE at the Group 13 elements, B and Al. These elements have the first np electrons, which are removed more easily because the resulting ion has a filled (stable) ns sublevel. For Al, for example,

- In Periods 2 and 3, once again, there are dips at the Group 16 elements, O and S. These elements have a fourth np electron, the first to pair up with another np electron, and electron-electron repulsions raise the orbital energy. The fourth np electron is easier to remove because doing so relieves the repulsions and leaves a half-filled (stable) np sublevel. For S, for example,

**SAMPLE PROBLEM 8.3****Ranking Elements by First Ionization Energy**

Problem Using the periodic table only, rank the elements in each set in order of decreasing IE_1 :

(a) Kr, He, Ar

(b) Sb, Te, Sn

(c) K, Ca, Rb

(d) I, Xe, Cs

Plan We find the elements in the periodic table and then apply the general trends of decreasing IE_1 down a group and increasing IE_1 across a period.

Solution (a) $He > Ar > Kr$. These are in Group 18, and IE_1 decreases down a group.

(b) $Te > Sb > Sn$. These are in Period 5, and IE_1 increases across a period.

(c) $Ca > K > Rb$. IE_1 of K is larger than IE_1 of Rb because K is higher in Group 1. IE_1 of Ca is larger than IE_1 of K because Ca is farther to the right in Period 4.

(d) $Xe > I > Cs$. IE_1 of I is smaller than IE_1 of Xe because I is farther to the left. IE_1 of I is larger than IE_1 of Cs because I is farther to the right and in the previous period.

Check Because trends in IE_1 are generally the opposite of the trends in size, you can rank the elements by size and check that you obtain the reverse order.

FOLLOW-UP PROBLEMS

8.3A Rank the elements in each set in order of *increasing* IE_1 :

(a) Sb, Sn, I (b) Na, Mg, Cs

8.3B Rank the elements in each set in order of *decreasing* IE_1 :

(a) O, As, Rb (b) Sn, Cl, Si

SOME SIMILAR PROBLEMS 8.52 and 8.53

Successive Ionization Energies The *second* ionization energy (IE_2) removes a second electron. Since this electron is pulled away from a positive ion, more energy is required for its removal and IE_2 is always larger than IE_1 :

For a given element, IE_1 , IE_2 , and so on increase because each electron is pulled away from a species with a higher positive charge. This increase includes an enormous jump *after* the outer (valence) electrons have been removed because *much* more energy is needed to remove an inner (core) electron (Figure 8.16).

Table 8.4 shows successive ionization energies for Period 2 and the first element in Period 3. Move across the row of values for any element, and you reach a point that separates relatively low from relatively high IE values (*shaded area*). For example, follow the values for boron (B): IE_1 (0.80 MJ/mol) is lower than IE_2 (2.43 MJ/mol), which is lower than IE_3 (3.66 MJ/mol), which is *much* lower than IE_4 (25.02 MJ/mol). From this jump, we know that boron has three electrons in the highest energy level ($1s^2 2s^2 2p^1$). Because they are so difficult to remove, *core electrons are not involved in reactions*.

Figure 8.16 The first three ionization energies of beryllium. Beryllium has two valence electrons, so IE_3 is much larger than IE_2 .

Table 8.4 Successive Ionization Energies of the Elements Lithium Through Sodium

Z	Element	Number of Valence Electrons	Ionization Energy (MJ/mol)*									
			IE_1	IE_2	IE_3	IE_4	IE_5	IE_6	IE_7	IE_8	IE_9	IE_{10}
3	Li	1	0.52	7.30	11.81							
4	Be	2	0.90	1.76	14.85	21.01						
5	B	3	0.80	2.43	3.66	25.02	32.82					
6	C	4	1.09	2.35	4.62	6.22	37.83	47.28				
7	N	5	1.40	2.86	4.58	7.48	9.44	53.27	64.36			
8	O	6	1.31	3.39	5.30	7.47	10.98	13.33	71.33	84.08

*MJ/mol, or megajoules per mole = 10^3 kJ/mol.

SAMPLE PROBLEM 8.4 | Identifying an Element from Its Ionization Energies

Problem Name the Period 3 element with the following ionization energies (kJ/mol), and write its full electron configuration:

IE ₁	IE ₂	IE ₃	IE ₄	IE ₅	IE ₆
1012	1903	2910	4956	6278	22,230

Plan We look for a large jump in the IE values, which occurs after all valence electrons have been removed. Then we refer to the periodic table to find the Period 3 element with this number of valence electrons and write its electron configuration.

Solution The large jump occurs after IE₅, indicating that the element has five valence electrons; the element is in Group 15 since the elements in that group have a valence shell electron configuration of ns^2np^3 and thus have 5 valence electrons. This Period 3 element is phosphorus (P; $Z = 15$). Its full electron configuration is $1s^22s^22p^63s^23p^3$.

FOLLOW-UP PROBLEMS

8.4A Element Q is in Period 3 and has the following ionization energies (in kJ/mol):

IE ₁	IE ₂	IE ₃	IE ₄	IE ₅	IE ₆
577	1816	2744	11,576	14,829	18,375

Name element Q, and write its full electron configuration.

8.4B Write the condensed electron configurations of the elements Rb, Sr, and Y. Which has the *highest* IE₂? Which has the highest IE₃?

SOME SIMILAR PROBLEMS 8.54–8.57

Trends in Electron Affinity

The **electron affinity (EA)** is the energy change accompanying the *addition* of 1 mol of electrons to 1 mol of gaseous atoms or ions. The *first electron affinity* (EA₁) refers to the formation of 1 mol of monovalent (1−) gaseous anions:

As with ionization energy, there is a first electron affinity, a second, and so forth. The first electron is *attracted* by the atom's nucleus, so, in most cases, EA₁ is *negative* (energy is released), analogous to the negative ΔH for an exothermic reaction.* But the second electron affinity (EA₂) is always positive because energy must be *absorbed* to overcome electrostatic repulsions and add another electron to a negative ion.

Factors other than Z_{eff} and atomic size affect electron affinities, so trends are not regular, as are those for size and IE₁. The many exceptions arise from changes in sublevel energy and electron-electron repulsion:

- *Down a group.* We might expect a smooth decrease (smaller negative number) down a group because atomic size increases, and the nucleus is farther away from an electron being added. But only Group 1 exhibits this behavior (Figure 8.17).
- *Across a period.* We might expect a regular increase (larger negative number) across a period because atomic size decreases, and higher Z_{eff} should attract the electron being added more strongly. There is an overall left-to-right increase, but it is not at all regular.

1						18
H −72.8	2					He (0.0)
Li −59.6	Be ≤0					Ne (+29)
Na −52.9	Mg ≤0					Ar (+35)
K −48.4	Ca −2.37					Kr (+39)
Rb −46.9	Sr −5.03					Xe (+41)
Cs −45.5	Ba −13.95					Rn (+41)
		13	14	15	16	17
		B −26.7	C −122	N +7	O −141	F −328
		Al −42.5	Si −134	P −72.0	S −200	Cl −349
		Ga −28.9	Ge −119	As −78.2	Se −195	Br −325
		In −28.9	Sn −107	Sb −103	Te −190	I −295
		Tl −19.3	Pb −35.1	Bi −91.3	Po −183	At −270

Figure 8.17 Electron affinities of the main-group elements (in kJ/mol). Values for Group 18 are estimates, which is indicated by parentheses.

*Some tables of EA₁ values list them as positive values because that quantity of energy would be *absorbed* to remove an electron from the anion.

Despite these irregularities, relative values of IE and EA show three general behavior patterns:

1. *Reactive nonmetals.* Members of Group 16 and especially Group 17 (the halogens) have high IEs and highly negative (exothermic) EAs: these elements lose electrons with difficulty but attract them strongly. Therefore, *in their ionic compounds, they form negative ions.*
2. *Reactive metals.* Members of Groups 1 and 2 have low IEs and slightly negative (exothermic) EAs: they lose electrons easily but attract them weakly, if at all. Therefore, *in their ionic compounds, they form positive ions.*
3. *Noble gases.* Members of Group 18 have very high IEs and slightly positive (endothermic) EAs: *they tend **not** to lose or gain electrons.* In fact, only the larger members of the group (Kr, Xe, and Rn) form compounds at all.

Summary of Section 8.3

- › Trends in three atomic properties are summarized in Figure 8.18.
- › Atomic size (half the distance between nuclei of adjacent atoms) increases down a main group and decreases across a period. In a transition series, size remains relatively constant.
- › First ionization energy (the energy required to remove a mole of electrons from a mole of gaseous atoms or ions) is inversely related to atomic size: IE_1 decreases down a main group and increases across a period.
- › Successive ionization energies of an element show a very large increase after all valence electrons have been removed, because the first inner (core) electron is in an orbital of much lower energy and so is held very tightly.
- › Electron affinity (the energy involved in adding a mole of electrons to a mole of gaseous atoms or ions) shows many variations from expected trends.
- › Based on the relative sizes of IEs and EAs, Group 1 and 2 elements tend to form cations, and Group 16 and 17 elements tend to form anions in ionic compounds. Group 18 elements are very unreactive.

Figure 8.18 Trends in three atomic properties. For electron affinity, the dashed arrows indicate that there are numerous exceptions to the expected trends.

8.4

ATOMIC PROPERTIES AND CHEMICAL REACTIVITY

All physical and chemical behaviors of the elements and their compounds are based on electron configuration and effective nuclear charge. In this section, you'll see how atomic properties determine metallic behavior and the properties of ions.

Trends in Metallic Behavior

The three general classes of elements have distinguishing properties:

- *Metals*, found in the left and lower three-quarters of the periodic table, are typically shiny solids, have moderate to high melting points, are good conductors of heat and electricity, can be machined into wires and sheets, and lose electrons to nonmetals.
- *Nonmetals*, found in the upper right quarter of the table, are typically not shiny, have relatively low melting points, are poor conductors, are mostly crumbly solids or gases, and tend to gain electrons from metals.
- *Metalloids*, found between the other two classes, have intermediate properties.

Thus, *metallic behavior decreases from left to right across a period and increases down a group in the periodic table* (Figure 8.19).

Remember, though, that some elements don't fit these categories: as graphite, non-metallic carbon is a good electrical conductor; the nonmetal iodine is shiny; metallic gallium melts in your hand; mercury is a liquid; and iron is brittle. Despite such exceptions, in this discussion, we'll make several generalizations about metallic behavior and its applications to redox behavior and the acid-base properties of oxides.

Figure 8.19 Trends in metallic behavior. (Hydrogen appears next to helium.)

Relative Tendency to Lose or Gain Electrons

Metals tend to lose electrons to nonmetals during reactions:

1. *Down a main group.* The increase in metallic behavior

Figure 8.20 Metallic behavior in Group 15 and Period 3. Moving down from N to Bi, there is an *increase* in metallic behavior. Moving across from Na to Cl, there is a *decrease* in metallic behavior.

Source: Stephen Frisch/McGraw Hill

down a group is consistent with an increase in size and a decrease in IE and is most obvious in groups with more than one class of element, such as Group 15 (Figure 8.20, *vertical*): *elements at the top can form anions, and those at the bottom can form cations.* Nitrogen (N) is a gaseous nonmetal, and phosphorus (P) is a soft nonmetal; both occur occasionally as 3− anions in their compounds. Arsenic (As) and antimony (Sb) are metalloids, with Sb the more metallic, and neither forms ions readily.

Bismuth (Bi) is a typical metal, forming a 3+ cation in its mostly ionic compounds. Groups 13, 14, and 16 show a similar trend. But, even in Group 2, which contains only metals, the tendency to form cations increases down the group: beryllium (Be) forms covalent compounds with nonmetals, whereas all compounds of barium (Ba) are ionic.

2. *Across a period.* The decrease in metallic behavior across a period is consistent with a decrease in size, an increase in IE, and a more favorable (more negative) EA. Consider Period 3 (see Figure 8.20, *horizontal*): *elements at the left tend to form cations, and those at the right tend to form anions.* Sodium and magnesium are metals that occur as Na⁺ and Mg²⁺ in seawater, minerals, and organisms. Aluminum is metallic physically and occurs as Al³⁺ in some compounds, but it bonds covalently in most others. Silicon (Si) is a shiny metalloid that does not occur as a monatomic ion. Phosphorus is a white, waxy nonmetal that occurs rarely as P^{3−}, whereas crumbly, yellow sulfur exists as S^{2−} in many compounds, and gaseous, yellow-green chlorine occurs in nature almost always as Cl[−].

Redox Behavior of the Main-Group Elements

Closely related to an element's tendency to lose or gain electrons is its redox behavior—that is, whether it behaves as an oxidizing or reducing agent. Redox behavior is closely related to atomic properties:

- With their low IEs and small EAs, the members of Groups 1 and 2 lose electrons readily, so they are *strong reducing agents* and become oxidized.
- With their high IEs and large EAs, nonmetals in Groups 16 and 17 gain electrons readily, so they are *strong oxidizing agents* and become reduced.

Acid-Base Behavior of Oxides Metals are also distinguished from nonmetals by the acid-base behavior of their oxides in water:

- Most main-group metals *transfer* electrons to oxygen, so their *oxides are ionic*. In water, these oxides act as *bases*, producing OH^- ions from O^{2-} and reacting with acids. Calcium oxide is an example (Figure 8.21).
- Nonmetals *share* electrons with oxygen, so *nonmetal oxides are covalent*. They react with water to form *acids*, producing H^+ ions and reacting with bases. Tetraphosphorus decoxide is an example (see Figure 8.21).

Some metals and many metalloids form oxides that are **amphoteric**: they can act as acids *or* bases in water.

In Figure 8.22, the acid-base behavior of some common oxides of elements in Group 15 and Period 3 is shown, with a gradient from blue (basic) to red (acidic):

1. As elements become more metallic down a group (larger size and smaller IE), their oxides become more basic. In Group 15, dinitrogen pentoxide, N_2O_5 , forms the strong acid HNO_3 :

Tetraphosphorus decoxide, P_4O_{10} , forms the weaker acid H_3PO_4 :

The oxide of the metalloid arsenic is weakly acidic, whereas that of the metalloid antimony is weakly basic. Bismuth, the most metallic of the group, forms a basic oxide that is insoluble in water but reacts with acid to yield a salt and water:

2. As the elements become less metallic across a period (smaller size and higher IE), their oxides become more acidic. In Period 3, Na_2O and MgO are strongly basic, and amphoteric aluminum oxide (Al_2O_3) reacts with acid or with base:

Silicon dioxide is weakly acidic, forming a salt and water with base:

The common oxides of phosphorus, sulfur, and chlorine form acids of increasing strength: H_3PO_4 , H_2SO_4 , and HClO_4 .

Properties of Monatomic Ions

So far, we have focused on the reactants—the atoms—in the process of electron loss and gain. Now we focus on the products—the ions—considering their electron configurations, magnetic properties, and sizes.

Figure 8.21 Oxide acidity. In water, metal oxides are basic (left), and nonmetal oxides are acidic (right). The colors are due to the presence of acid-base indicators. Source: Stephen Frisch/McGraw Hill

4			Kr	Rb		5
5	I		Xe	Cs	Ba	6
	Gain electrons			Lose electrons		

Figure 8.23 Main-group elements whose ions have noble gas electron configurations.

Electron Configurations of Main-Group Ions Atoms of the noble gases have very low reactivity because their highest energy level is *filled* (ns^2np^6). Thus, atoms of other elements tend to lose or gain electrons to obtain a filled outer level—a noble gas configuration. Elements at either end of a period form ions that are **isoelectronic** (Greek, *iso*, “same”) with the nearest noble gas (Figure 8.23; see also Figure 2.16).

- **Anions.** Nonmetal atoms *gain electrons* in the p orbitals of highest n value. Elements in Group 16 *gain two* electrons and elements in Group 17 *gain one* electron and become isoelectronic with the *next* noble gas. For oxygen and bromine, for example:

- **Cations of s -block metals.** The Group 1 and 2 metals *lose all electrons* with the highest n value to become isoelectronic with the *previous* noble gas. Group 1 elements lose one electron while Group 2 elements lose two electrons, as shown for Na and Sr:

- **Cations of p -block metals.** Metals in Groups 13 through 15 *lose np electrons* before losing ns electrons. For the heavier elements in these groups, there are two possible cations; one cation is formed when only the np electrons are lost and a second cation results when the ns electrons are also lost. For example, for tin, Sn:

When both ns and np electrons are lost, as in Sn^{4+} , the metal atom attains the stability of empty ns and np sublevels and a filled inner $(n-1)d$ sublevel. Alternatively, when the metal atom loses just its np electrons, as in Sn^{2+} , the stability of a filled ns and $(n-1)d$ sublevels is obtained.

Note that while aluminum in Group 13 loses its ns and np electrons to form Al^{3+} , which is isoelectronic with Ne, the other metals in Groups 13–15 lose ns and np electrons, but they do not lose the $(n-1)d$ electrons and thus are not isoelectronic with a noble gas.

SAMPLE PROBLEM 8.5

Writing Electron Configurations of Main-Group Ions

Problem Using condensed electron configurations, write equations representing the formation of the ion(s) of the following elements:

(a) Iodine ($Z = 53$)

(b) Potassium ($Z = 19$)

(c) Indium ($Z = 49$)

Plan We identify the element's position in the periodic table and recall that

- Ions of elements in Groups 1, 2, 16, and 17 are isoelectronic with the nearest noble gas.
- Metals in Groups 13 to 15 lose the ns and np electrons or just the np .

Solution (a) Iodine is in Group 17, so it gains one electron, and I^- is isoelectronic with xenon:

(b) Potassium is in Group 1, so it loses one electron; K^+ is isoelectronic with argon:

(c) Indium is in Group 13, so it loses either three electrons to form In^{3+} or one to form In^+ :

Check Be sure that the number of electrons in the ion's electron configuration, plus the number gained or lost to form the ion, equals Z .

FOLLOW-UP PROBLEMS

8.5A Using condensed electron configurations, write equations representing the formation of the ion(s) of the following elements:

- (a) Ba ($Z = 56$) (b) S ($Z = 16$) (c) Pb ($Z = 82$)

8.5B Using condensed electron configurations, write equations representing the formation of the ion(s) of the following elements:

- (a) F ($Z = 9$) (b) Tl ($Z = 81$) (c) Mg ($Z = 12$)

SOME SIMILAR PROBLEMS 8.71–8.74

Electron Configurations of Transition Metal Ions In contrast to many main-group ions, *transition metal ions rarely attain a noble gas configuration*. Aside from the Period 4 elements scandium, which forms Sc^{3+} , and titanium, which occasionally forms Ti^{4+} , *a transition element typically forms more than one cation by losing all of its ns and some of its $(n - 1)d$ electrons*.

Because the $(n - 1)d$ electrons are held tightly and shield those in the outer sublevel, *the ns electrons of a transition metal are lost before the $(n - 1)d$ electrons*. Thus, ns electrons are added before $(n - 1)d$ electrons to form the *atom* and are lost before them to form the *ion*, the so-called first-in, first-out rule.

For example, consider the formation of Fe^{2+} and Fe^{3+} ions:

Magnetic Properties of Transition Metal Ions We learn a great deal about an element's electron configuration from atomic spectra, and magnetic studies provide additional evidence.

Recall that electron spin generates a tiny magnetic field (see Figure 7.18); because of this, an atom or ion with at least one unpaired electron is attracted to an external magnetic field and is said to be **paramagnetic**. A species with all of its electrons paired is **diamagnetic**: it is not attracted (and is slightly repelled) by the magnetic field (Figure 8.24). Many transition metals and their compounds are paramagnetic because their atoms and ions have unpaired electrons.

Let's consider three examples of how magnetic studies provide evidence for a proposed electron configuration:

1. *The Ti^{2+} ion.* Spectral analysis of titanium metal yields the electron configuration $[\text{Ar}] 4s^2 3d^2$, and experiment shows that the metal is paramagnetic, which indicates the presence of unpaired electrons. Spectral analysis shows that the Ti^{2+} ion is $[\text{Ar}] 3d^2$, indicating loss of the $4s$ electrons. In support of the spectra, magnetic studies show that Ti^{2+} compounds are paramagnetic:

The partial orbital diagrams are

If Ti lost its $3d$ electrons to form Ti^{2+} , its compounds would be diamagnetic.

Figure 8.24 Measuring the magnetic behavior of a sample. The substance is weighed with the external magnetic field “off.” **A**, If the substance is diamagnetic (has all *paired* electrons), its apparent mass is unaffected (or slightly reduced) with the field “on.” **B**, If the substance is paramagnetic (has *unpaired* electrons), its apparent mass increases.

2. *The Fe^{3+} ion.* An increase in paramagnetism occurs when iron metal (Fe) becomes Fe^{3+} in compounds, which indicates an increase in the number of unpaired electrons. This fact is consistent with Fe losing its 4s pair and one electron of a 3d pair:

3. *The Cu^+ and Zn^{2+} ions.* Copper (Cu) metal is paramagnetic, but zinc (Zn) is diamagnetic. The Cu^+ and Zn^{2+} ions are diamagnetic, too. These observations are consistent with the ions being isoelectronic, which means 4s electrons were lost:

Student Hot Spot

Student data indicate that you may struggle with writing electron configurations of ions. Access the eBook to view an additional Learning Resource video on this topic.

SAMPLE PROBLEM 8.6

Writing Electron Configurations and Predicting Magnetic Behavior of Transition Metal Ions

Problem Use condensed electron configurations to write an equation for the formation of each transition metal ion, and predict whether it is paramagnetic:

- (a) Co^{3+} ($Z = 27$) (b) Cr^{3+} ($Z = 24$) (c) Hg^{2+} ($Z = 80$)

Plan We first write the condensed electron configuration of the atom, recalling the irregularity for Cr. Then we remove electrons, beginning with ns electrons, to attain the ion charge. If unpaired electrons are present, the ion is paramagnetic.

Solution

There are four unpaired e^{-} , so Co^{3+} is **paramagnetic**.

There are three unpaired e^{-} , so Cr^{3+} is **paramagnetic**.

The 4f and 5d sublevels are filled, so there are no unpaired e^{-} : Hg^{2+} is **not paramagnetic**.

Check We removed the ns electrons first, and the sum of the lost electrons and those in the electron configuration of the ion equals Z .

FOLLOW-UP PROBLEMS

8.6A Write the condensed electron configuration of each transition metal ion, and predict whether it is paramagnetic:

- (a) V^{3+} ($Z = 23$) (b) Ni^{2+} ($Z = 28$) (c) La^{3+} ($Z = 57$)

8.6B Write the condensed electron configuration of each transition metal ion, and give the number of unpaired electrons:

- (a) Zr^{2+} ($Z = 40$) (b) Os^{3+} ($Z = 76$) (c) Co^{2+} ($Z = 27$)

SOME SIMILAR PROBLEMS 8.78–8.80

Ionic Size vs. Atomic Size The **ionic radius** is a measure of the size of an ion and is obtained from the distance between the nuclei of adjacent ions in a crystalline ionic compound (Figure 8.25). From the relation between effective nuclear charge (Z_{eff}) and atomic size, we can predict the size of an ion relative to its parent atom:

- *Cations are smaller than parent atoms.* When a cation forms, electrons are *removed* from the outer level. The resulting decrease in shielding allows the nucleus to pull the remaining electrons closer.
- *Anions are larger than parent atoms.* When an anion forms, electrons are *added* to the outer level. The increases in shielding and electron repulsions mean the electrons occupy more space.

Figure 8.26 shows the radii of some main-group ions and their parent atoms; we can make the following observations:

1. *Down a group, ionic size increases* because n increases.
2. *Across a period, the pattern is complex.* For instance, consider Period 3:
 - *Among cations*, the increase in Z_{eff} from left to right makes Na^+ larger than Mg^{2+} , which is larger than Al^{3+} . Across a period, cation size decreases with increasing charge.
 - *From last cation to first anion*, a great jump in size occurs: we are *adding* electrons rather than removing them, so repulsions increase sharply. For instance, P^{3-} has eight more electrons than Al^{3+} .
 - *Among anions*, the increase in Z_{eff} from left to right makes P^{3-} larger than S^{2-} , which is larger than Cl^- . Across a period, anion size decreases with decreasing charge.
 - *Within an isoelectronic series*, these factors have striking results. Within the dashed outline in Figure 8.26, the ions are isoelectronic with neon. Period 2

Figure 8.25 Ionic radius. Cation radius (r^+) and anion radius (r^-) together make up the distance between nuclei.

Figure 8.26 Ionic vs. atomic radii. Atomic radii (color) and ionic radii (gray) are given in picometers. Metal atoms (blue) form smaller positive ions, and nonmetal atoms (red) form larger negative ions. Ions in the dashed outline are isoelectronic with neon.

anions are much larger than Period 3 cations because the same number of electrons are attracted by an increasing nuclear charge. The size pattern is

3. *Cation size decreases with increasing charge.* When a metal forms more than one cation, *the greater the ionic charge, the smaller the ionic radius.* With the two ions of iron, for example, Fe^{3+} has one fewer electron than Fe^{2+} , so shielding is reduced somewhat, and the same nucleus is attracting fewer electrons. As a result, Z_{eff} increases, so Fe^{3+} (65 pm) is smaller than Fe^{2+} (78 pm).

SAMPLE PROBLEM 8.7 | Ranking Ions by Size

Problem Rank each set of ions in order of *decreasing* size, and explain your ranking:

- (a) Ca^{2+} , Sr^{2+} , Mg^{2+} (b) K^+ , S^{2-} , Cl^- (c) Au^+ , Au^{3+}

Plan We find the position of each element in the periodic table and apply the ideas presented in the text.

Solution (a) Mg^{2+} , Ca^{2+} , and Sr^{2+} are all from Group 2, so their sizes decrease up the group: $\text{Sr}^{2+} > \text{Ca}^{2+} > \text{Mg}^{2+}$.

(b) The ions K^+ , S^{2-} , and Cl^- are isoelectronic. S^{2-} has a lower Z_{eff} than Cl^- , so it is larger. K^+ is a cation and has the highest Z_{eff} , so it is smallest: $\text{S}^{2-} > \text{Cl}^- > \text{K}^+$.

(c) Au^+ has a lower charge than Au^{3+} , so it is larger: $\text{Au}^+ > \text{Au}^{3+}$.

FOLLOW-UP PROBLEMS

8.7A Rank the ions in each set in order of *increasing* size:

- (a) Cl^- , Br^- , F^- (b) Na^+ , Mg^{2+} , F^- (c) Cr^{2+} , Cr^{3+}

8.7B Rank the ions in each set in order of *decreasing* size:

- (a) S^{2-} , P^{3-} , Cl^- (b) Rb^+ , K^+ , Cs^+ (c) I^- , Ba^{2+} , Cs^+

SOME SIMILAR PROBLEMS 8.83 and 8.84

Summary of Section 8.4

- › Metallic behavior correlates with large atomic size and low ionization energy. Thus, metallic behavior increases down a group and decreases from left to right across a period.
- › Elements in Groups 1 and 2 are strong reducing agents since they lose electron readily; nonmetals in Groups 16 and 17 are strong oxidizing agents since they readily gain electrons.
- › Within the main groups, metal oxides are basic and nonmetal oxides acidic. Thus, oxides become more acidic across a period and more basic down a group.
- › Many main-group elements form ions that are isoelectronic with the nearest noble gas.
- › Metals in Groups 13 to 15 lose either their np electrons or both their ns and np electrons.
- › Transition metals lose ns electrons before $(n - 1)d$ electrons and commonly form more than one ion.
- › Many transition metals and their compounds are paramagnetic because their atoms (or ions) have unpaired electrons.
- › Cations are smaller and anions larger than their parent atoms. Ionic radius increases down a group. Across a period, ionic radii generally decrease, but a large increase occurs from the last cation to the first anion.

CHAPTER REVIEW GUIDE

Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

Understand These Concepts

1. The meaning of the periodic law and the arrangement of elements by atomic number (Introduction)
2. How the Pauli exclusion principle applies to orbital filling (§8.1)
3. The effects of nuclear charge, shielding, and penetration on the splitting of energy levels; the meaning of effective nuclear charge (§8.1)
4. How the arrangement of the periodic table is based on the order of sublevel energies (§8.2)
5. How sublevels are filled in main-group and transition elements; the importance of Hund's rule (§8.2)
6. The distinction among inner, outer, and valence electrons (§8.2)
7. How outer electron configuration within a group is related to chemical behavior (§8.2)
8. The meaning of atomic radius, ionization energy, and electron affinity (§8.3)
9. How n value and effective nuclear charge give rise to the periodic trends of atomic size and ionization energy (§8.3)
10. The importance of core electrons to the pattern of successive ionization energies (§8.3)
11. How atomic properties relate to the tendency to form ions (§8.3)
12. The general properties of metals and nonmetals (§8.4)
13. How vertical and horizontal trends in metallic behavior are related to ion formation and oxide acidity (§8.4)
14. How atomic size and IE relate to redox behavior (§8.4)
15. How main-group ions become isoelectronic with the nearest noble gas (§8.4)
16. How transition elements form ions by losing ns electrons first (§8.4)
17. The origin of paramagnetic and diamagnetic behavior (§8.4)
18. The relation between ionic and atomic size and the trends in ionic size (§8.4)

Master These Skills

1. Writing full and condensed electron configurations for an element (SP 8.1)
2. Using periodic trends to rank elements by atomic size and first ionization energy (SPs 8.2, 8.3)
3. Identifying an element from its successive ionization energies (SP 8.4)
4. Writing electron configurations of main-group and transition metal ions and predicting magnetic behavior of transition metal ions (SPs 8.5, 8.6)
5. Using periodic trends to rank ions by size (SP 8.7)

Key Terms

Page numbers appear in parentheses.

actinides (337)	electron affinity (EA) (346)	isoelectronic (350)	penetration (330)
amphoteric (349)	electron configuration (327)	lanthanides (rare earths) (337)	periodic law (327)
atomic size (340)	Hund's rule (332)	metallic radius (340)	shielding (329)
aufbau principle (331)	inner (core) electrons (336)	orbital diagram (331)	transition elements (334)
covalent radius (340)	inner transition elements (337)	outer electrons (336)	valence electrons (336)
diamagnetic (351)	ionic radius (353)	paramagnetic (351)	
effective nuclear charge (Z_{eff}) (329)	ionization energy (IE) (342)	Pauli exclusion principle (328)	

Key Equations and Relationships

Page numbers appear in parentheses.

8.1 Defining the energy order of sublevels in terms of the angular momentum quantum number (l value) (330):

Order of sublevel energies: $s < p < d < f$

8.2 Meaning of the first ionization energy (343):

CHAPTER PRACTICE TEST

The answers to the Practice Test problems are shown below and the full solutions can be found in the e-book.

1. Choose all of the statements below that are correct.

- I. Larger atoms generally have smaller ionization energy values.

II. An element with the following ionization energies (in MJ/mol) has three valence electrons:

$$\text{IE}_1 = 0.80 \quad \text{IE}_2 = 2.43 \quad \text{IE}_3 = 3.66 \quad \text{IE}_4 = 25.02$$

III. Potassium's second ionization energy is larger than calcium's second ionization energy.

CHAPTER PRACTICE TEST (continued)

- (a) I (b) II (c) III (d) II and III
(e) I and III (f) I, II, and III

2. Which of the following atoms could have a valence electron with the quantum numbers $n = 3$, $l = 2$, $m_l = -1$, $m_s = +\frac{1}{2}$?

- (a) S (b) Cl (c) Ti (d) Br (e) Pd

3. Select a possible correct set of quantum numbers (n , l , m_l , m_s) for the first electron removed in the formation of a cation for strontium, Sr.

- (a) 5, 1, 0, $-\frac{1}{2}$ (b) 5, 1, 0, $+\frac{1}{2}$ (c) 5, 0, 1, $+\frac{1}{2}$
(d) 4, 0, 0, $+\frac{1}{2}$ (e) 5, 0, 0, $-\frac{1}{2}$

4. How many electrons can be described by the quantum numbers $n = 4$, $l = 2$, $m_s = +\frac{1}{2}$?

- (a) 1 (b) 2 (c) 3 (d) 5 (e) 10

5. Which of the following species are isoelectronic?

Γ^- , Pb^{4+} , Xe , Ba^{2+} and Sn^{2+}

- (a) Γ^- , Xe , and Ba^{2+} (b) Γ^- , Pb^{4+} , Xe , and Ba^{2+}
(c) Pb^{4+} and Sn^{2+} (d) Pb^{4+} and Ba^{2+}
(e) None (f) All of them

6. Which of the following cations has two unpaired electrons?

- (a) Ni^{2+} (b) Sn^{2+} (c) Pb^{4+} (d) Fe^{3+} (e) Ca^{2+}

7. Place the following ions in order from smallest to largest size: S^{2-} , Na^+ , Cl^- , Mg^{2+} , and K^+ .

- (a) $\text{K}^+ < \text{Mg}^{2+} < \text{Na}^+ < \text{Cl}^- < \text{S}^{2-}$
(b) $\text{Mg}^{2+} < \text{Na}^+ < \text{K}^+ < \text{Cl}^- < \text{S}^{2-}$
(c) $\text{K}^+ < \text{Mg}^{2+} < \text{S}^{2-} < \text{Na}^+ < \text{Cl}^-$
(d) $\text{Na}^+ < \text{S}^{2-} < \text{Cl}^- < \text{Mg}^{2+} < \text{K}^+$
(e) $\text{Cl}^- < \text{S}^{2-} < \text{Mg}^{2+} < \text{Na}^+ < \text{K}^+$

8. An atom of Sn has _____ inner (core) electrons, _____ outer electrons, and _____ valence electrons.

- (a) 36, 10, 4 (b) 46, 2, 4 (c) 46, 4, 4 (d) 36, 2, 12
(e) 46, 2, 12

9. Which element has exactly 13 electrons in p orbitals?

- (a) K (b) Nb (c) Fr (d) Ga (e) Al

10. What is the condensed ground-state electron configuration for At ($Z = 85$)?

- (a) $[\text{Xe}] 6s^2 5f^{14} 6d^{10} 6p^5$ (b) $[\text{Xe}] 6s^2 5d^{10} 6p^5$
(c) $[\text{Xe}] 7s^2 4f^{14} 5d^{10} 7p^5$ (d) $[\text{Xe}] 6s^2 5f^{14} 5d^{10} 6p^5$
(e) $[\text{Xe}] 6s^2 4f^{14} 5d^{10} 6p^5$

Answers: 1. f; 2. c; 3. e; 4. d; 5. a; 6. a; 7. b; 8. c; 9. d; 10. e

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

8.1A (a) For Ni, $1s^2 2s^2 2p^6 3s^2 3p^6 4s^2 3d^8$; $[\text{Ar}] 4s^2 3d^8$

Ni has 2 unpaired electrons and 18 inner, 2 outer, and 10 valence electrons.

(b) For Sr, $1s^2 2s^2 2p^6 3s^2 3p^6 4s^2 3d^{10} 4p^6 5s^2$; $[\text{Kr}] 5s^2$

Sr has no unpaired electrons and 36 inner, 2 outer, and 2 valence electrons.

(c) For Po, $1s^2 2s^2 2p^6 3s^2 3p^6 4s^2 3d^{10} 4p^6 5s^2 4d^{10} 5p^6 6s^2 4f^{14} 5d^{10} 6p^4$; $[\text{Xe}] 6s^2 4f^{14} 5d^{10} 6p^4$

Po has 2 unpaired electrons and 78 inner, 6 outer, and 6 valence electrons.

8.1B (a) As; $1s^2 2s^2 2p^6 3s^2 3p^6 4s^2 3d^{10} 4p^3$; $[\text{Ar}] 4s^2 3d^{10} 4p^3$;

As has 28 inner, 5 outer, and 5 valence electrons.

(b) Zr; $1s^2 2s^2 2p^6 3s^2 3p^6 4s^2 3d^{10} 4p^6 5s^2 4d^2$; $[\text{Kr}] 5s^2 4d^2$;

Zr has 36 inner, 2 outer, and 4 valence electrons.

(c) I; $1s^2 2s^2 2p^6 3s^2 3p^6 4s^2 3d^{10} 4p^6 5s^2 4d^{10} 5p^5$; $[\text{Kr}] 5s^2 4d^{10} 5p^5$;

I has 46 inner, 7 outer, and 7 valence electrons.

8.2A (a) $\text{Cl} < \text{Br} < \text{Se}$; (b) $\text{Xe} < \text{I} < \text{Ba}$

8.2B (a) $\text{Cs} > \text{As} > \text{S}$; (b) $\text{K} > \text{P} > \text{F}$

8.3A (a) $\text{Sn} < \text{Sb} < \text{I}$; (b) $\text{Cs} < \text{Na} < \text{Mg}$

8.3B (a) $\text{O} > \text{As} > \text{Rb}$; (b) $\text{Cl} > \text{Si} > \text{Sn}$

8.4A The large jump occurs after IE_3 , indicating that the element has three valence electrons and is in Group 13. Q is aluminum: $1s^2 2s^2 2p^6 3s^2 3p^1$.

8.4B Rb: $[\text{Kr}] 5s^1$; Sr: $[\text{Kr}] 5s^2$; Y: $[\text{Kr}] 5s^2 4d^1$ Highest IE_2 : Rb, since the second electron removed is a core electron, which is much more difficult to remove. Highest IE_3 : Sr, since the third electron removed is a core electron.

8.5A (a) $\text{Ba}([\text{Xe}] 6s^2) \rightarrow \text{Ba}^{2+}([\text{Xe}]) + 2e^-$

(b) $\text{S}([\text{Ne}] 3s^2 3p^4) + 2e^- \rightarrow \text{S}^{2-}([\text{Ne}] 3s^2 3p^6)$ (same as Ar)

(c) $\text{Pb}([\text{Xe}] 6s^2 4f^{14} 5d^{10} 6p^2) \rightarrow \text{Pb}^{2+}([\text{Xe}] 6s^2 4f^{14} 5d^{10}) + 2e^-$
 $\text{Pb}([\text{Xe}] 6s^2 4f^{14} 5d^{10} 6p^2) \rightarrow \text{Pb}^{4+}([\text{Xe}] 4f^{14} 5d^{10}) + 4e^-$

8.5B (a) $\text{F}([\text{He}] 2s^2 2p^5) + e^- \rightarrow \text{F}^-([\text{He}] 2s^2 2p^6)$ (same as Ne)

(b) $\text{Tl}([\text{Xe}] 6s^2 4f^{14} 5d^{10} 6p^1) \rightarrow \text{Tl}^+([\text{Xe}] 6s^2 4f^{14} 5d^{10}) + e^-$

$\text{Tl}([\text{Xe}] 6s^2 4f^{14} 5d^{10} 6p^1) \rightarrow \text{Tl}^{3+}([\text{Xe}] 4f^{14} 5d^{10}) + 3e^-$

(c) $\text{Mg}([\text{Ne}] 3s^2) \rightarrow \text{Mg}^{2+}([\text{Ne}]) + 2e^-$

8.6A (a) V: $[\text{Ar}] 4s^2 3d^3$; V^{3+} : $[\text{Ar}] 3d^3$; paramagnetic

(b) Ni: $[\text{Ar}] 4s^2 3d^8$; Ni^{2+} : $[\text{Ar}] 3d^8$; paramagnetic

(c) La: $[\text{Xe}] 6s^2 5d^1$; La^{3+} : $[\text{Xe}]$; not paramagnetic (diamagnetic)

8.6B (a) Zr: $[\text{Kr}] 5s^2 4d^2$; Zr^{2+} : $[\text{Kr}] 4d^2$; 2 unpaired electrons

(b) Os: $[\text{Xe}] 6s^2 4f^{14} 5d^6$; Os^{3+} : $[\text{Xe}] 4f^{14} 5d^5$; 5 unpaired electrons

(c) Co: $[\text{Ar}] 4s^2 3d^7$; Co^{2+} : $[\text{Ar}] 3d^7$; 3 unpaired electrons

8.7A (a) $\text{F}^- < \text{Cl}^- < \text{Br}^-$ Ion size increases down a group.

(b) $\text{Mg}^{2+} < \text{Na}^+ < \text{F}^-$ Across a period, cation size decreases with increasing charge; in a series of isoelectronic ions, anions are larger than the cations.

(c) $\text{Cr}^{3+} < \text{Cr}^{2+}$ Cation size decreases with increasing charge.

8.7B (a) $\text{P}^{3-} > \text{S}^{2-} > \text{Cl}^-$ Anion size decreases with decreasing charge.

(b) $\text{Cs}^+ > \text{Rb}^+ > \text{K}^+$ Ion size increases down a group.

(c) $\text{I}^- > \text{Cs}^+ > \text{Ba}^{2+}$ Across a period, cation size decreases with increasing charge; in a series of isoelectronic ions, anions are larger than the cations.

PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. Comprehensive Problems are based on material from any section or previous chapter.

Introduction

Concept Review Questions

8.1 What would be your reaction to a claim that a new element had been discovered and it fit between tin (Sn) and antimony (Sb) in the periodic table?

8.2 Based on results of his study of atomic x-ray spectra, Moseley discovered a relationship that replaced atomic mass as the criterion for ordering the elements. By what criterion are the elements now ordered in the periodic table? Give an example of a sequence of element order that was confirmed by Moseley's findings.

Skill-Building Exercises (grouped in similar pairs)

8.3 Before Mendeleev published his periodic table, German scientist Johann Döbereiner grouped elements with similar properties into "triads," in which the unknown properties of one member could be predicted by averaging known values of the properties of the others. To test this idea, predict the values of the following quantities:

- (a) The atomic mass of K from the atomic masses of Na and Rb
- (b) The melting point of Br_2 from the melting points of Cl_2 (-101.0°C) and I_2 (113.6°C) (actual value = -7.2°C)

8.4 To test Döbereiner's idea (Problem 8.3), predict:

- (a) The boiling point of HBr from the boiling points of HCl (-84.9°C) and HI (-35.4°C) (actual value = -67.0°C)
- (b) The boiling point of AsH_3 from the boiling points of PH_3 (-87.4°C) and SbH_3 (-17.1°C) (actual value = -55°C)

Characteristics of Many-Electron Atoms

Concept Review Questions

8.5 State the Pauli exclusion principle. What does it imply about the number and spin of electrons in an atomic orbital?

8.6 What is the key distinction between sublevel energies in one-electron species, such as the H atom, and those in many-electron species, such as the C atom? What factors lead to this distinction? Would you expect the pattern of sublevel energies in Be^{3+} to be more like that in H or that in C? Explain.

8.7 Define *shielding* and *effective nuclear charge*. What is the connection between the two?

8.8 What is penetration? How is it related to shielding? Use the penetration effect to explain the difference in relative orbital energies of a $3p$ and a $3d$ electron in the same atom.

Skill-Building Exercises (grouped in similar pairs)

8.9 How many electrons in an atom can have each of the following quantum numbers or sublevel designations?

- (a) $n = 2, l = 1$
- (b) $3d$
- (c) $4s$

8.10 How many electrons in an atom can have each of the following quantum numbers or sublevel designations?

- (a) $n = 2, l = 1, m_l = 0$
- (b) $5p$
- (c) $n = 4, l = 3$

8.11 How many electrons in an atom can have each of the following quantum numbers or sublevel designations?

- (a) $4p$
- (b) $n = 3, l = 1, m_l = +1$
- (c) $n = 5, l = 3$

8.12 How many electrons in an atom can have each of the following quantum numbers or sublevel designations?

- (a) $2s$
- (b) $n = 3, l = 2$
- (c) $6d$

The Quantum-Mechanical Model and the Periodic Table

(Sample Problem 8.1)

Concept Review Questions

8.13 State the periodic law, and explain its relation to electron configuration. (Use Na and K in your explanation.)

8.14 State Hund's rule in your own words, and show its application in the orbital diagram of the nitrogen atom.

8.15 How does the aufbau principle, in connection with the periodic law, lead to the format of the periodic table?

8.16 For main-group elements, are outer electron configurations similar or different within a group? Within a period? Explain.

8.17 For which blocks of elements are outer electrons the same as valence electrons? For which elements are d electrons often included among the valence electrons?

8.18 What is the electron capacity of the n th energy level? What is the capacity of the fourth energy level?

Skill-Building Exercises (grouped in similar pairs)

8.19 Write a full set of possible quantum numbers for each of the following:

- (a) The outermost electron in an Rb atom
- (b) The electron gained when an S^- ion becomes an S^{2-} ion
- (c) The electron lost when an Ag atom ionizes
- (d) The electron gained when an F^- ion forms from an F atom

8.20 Write a full set of possible quantum numbers for each of the following:

- (a) The outermost electron in an Li atom
- (b) The electron gained when a Br atom becomes a Br^- ion
- (c) The electron lost when a Cs atom ionizes
- (d) The highest energy electron in the ground-state B atom

8.21 Write the full ground-state electron configuration for each:

- (a) Rb
- (b) Ge
- (c) Ar

8.22 Write the full ground-state electron configuration for each:

- (a) Br
- (b) Mg
- (c) Se

8.23 Write the full ground-state electron configuration for each:

- (a) Cl
- (b) Si
- (c) Sr

8.24 Write the full ground-state electron configuration for each:

- (a) S
- (b) Kr
- (c) Cs

8.25 Draw a partial (valence-level) orbital diagram, and write the condensed ground-state electron configuration for each:

- (a) Ti
- (b) Cl
- (c) V

8.26 Draw a partial (valence-level) orbital diagram, and write the condensed ground-state electron configuration for each:

- (a) Ba (b) Co (c) Ag

8.27 Draw a partial (valence-level) orbital diagram, and write the condensed ground-state electron configuration for each:

- (a) Mn (b) P (c) Fe

8.28 Draw a partial (valence-level) orbital diagram, and write the condensed ground-state electron configuration for each:

- (a) Ga (b) Zn (c) Sc

8.29 Draw the partial (valence-level) orbital diagram, and write the symbol, group number, and period number of the element:

- (a) [He] $2s^2 2p^4$ (b) [Ne] $3s^2 3p^3$

8.30 Draw the partial (valence-level) orbital diagram, and write the symbol, group number, and period number of the element:

- (a) [Kr] $5s^2 4d^{10}$ (b) [Ar] $4s^2 3d^8$

8.31 Draw the partial (valence-level) orbital diagram, and write the symbol, group number, and period number of the element:

- (a) [Ne] $3s^2 3p^5$ (b) [Ar] $4s^2 3d^{10} 4p^3$

8.32 Draw the partial (valence-level) orbital diagram, and write the symbol, group number, and period number of the element:

- (a) [Ar] $4s^2 3d^5$ (b) [Kr] $5s^2 4d^2$

8.33 From each partial (valence-level) orbital diagram, write the condensed electron configuration and group number:

8.34 From each partial (valence-level) orbital diagram, write the condensed electron configuration and group number:

8.35 How many inner, outer, and valence electrons are present in an atom of each of the following elements?

- (a) O (b) Sn (c) Ca (d) Fe (e) Se

8.36 How many inner, outer, and valence electrons are present in an atom of each of the following elements?

- (a) Br (b) Cs (c) Cr (d) Sr (e) F

8.37 Identify each element below, and give the symbols of the other elements in its group:

- (a) [He] $2s^2 2p^1$ (b) [Ne] $3s^2 3p^4$ (c) [Xe] $6s^2 5d^1$

8.38 Identify each element below, and give the symbols of the other elements in its group:

- (a) [Ar] $4s^2 3d^{10} 4p^4$ (b) [Xe] $6s^2 4f^{14} 5d^2$ (c) [Ar] $4s^2 3d^5$

8.39 Identify each element below, and give the symbols of the other elements in its group:

- (a) [He] $2s^2 2p^2$ (b) [Ar] $4s^2 3d^3$ (c) [Ne] $3s^2 3p^3$

8.40 Identify each element below, and give the symbols of the other elements in its group:

- (a) [Ar] $4s^2 3d^{10} 4p^2$ (b) [Ar] $4s^2 3d^7$ (c) [Kr] $5s^2 4d^5$

Problems in Context

8.41 After an atom in its ground state absorbs energy, it exists in an excited state. Spectral lines are produced when the atom returns to its ground state. The yellow-orange line in the sodium spectrum, for example, is produced by the emission of energy when excited sodium atoms return to their ground state. Write the electron configuration and the orbital diagram of the first excited state of sodium. (*Hint:* The outermost electron is excited.)

8.42 One reason spectroscopists study excited states is to gain information about the energies of orbitals that are unoccupied in an atom's ground state. Each of the following electron configurations represents an atom in an excited state. Identify the element, and write its condensed ground-state configuration:

- (a) $1s^2 2s^2 2p^6 3s^1 3p^1$ (b) $1s^2 2s^2 2p^6 3s^2 3p^4 4s^1$
(c) $1s^2 2s^2 2p^6 3s^2 3p^6 4s^2 3d^4 4p^1$ (d) $1s^2 2s^2 2p^5 3s^1$

Trends in Three Atomic Properties

(Sample Problems 8.2 to 8.4)

Concept Review Questions

8.43 If the exact outer limit of an isolated atom cannot be measured, what criterion can we use to determine atomic radii? What is the difference between a covalent radius and a metallic radius?

8.44 Given the following partial (valence-level) electron configurations, (a) identify each element, (b) rank the four elements in order of increasing atomic size, and (c) rank them in order of increasing ionization energy:

8.45 In what region of the periodic table will you find elements with relatively high IEs? With relatively low IEs?

8.46 (a) Why do successive IEs of a given element always increase? (b) When the difference between successive IEs of a given element is exceptionally large (for example, between IE_1 and IE_2 of K), what do we learn about the element's electron configuration? (c) The bars represent the relative magnitudes of the first five ionization energies of an atom:

Identify the element, and write its complete electron configuration, assuming it comes from (i) Period 2; (ii) Period 3; (iii) Period 4.

8.47 In a plot of IE_1 for the Period 3 elements (see Figure 8.14), why do the values for elements in Groups 13 and 16 drop slightly below the generally increasing trend?

8.48 Which group in the periodic table has elements with high (endothermic) IE_1 and very negative (exothermic) first electron affinities (EA_1)? Give the charge on the ions these atoms form.

8.49 The EA_2 of an oxygen atom is positive, even though its EA_1 is negative. Why does this change of sign occur? Which other elements exhibit a positive EA_2 ? Explain.

Skill-Building Exercises (grouped in similar pairs)

8.50 Arrange each set in order of *increasing* atomic size:

- (a) Rb, K, Cs (b) C, O, Be
(c) Cl, K, S (d) Mg, K, Ca

8.51 Arrange each set in order of *decreasing* atomic size:

- (a) Ge, Pb, Sn (b) Sn, I, Sr
(c) F, Ne, Na (d) Be, Mg, Na

8.52 Arrange each set of atoms in order of *increasing* IE_1 :

- (a) Sr, Ca, Ba (b) N, B, Ne
(c) Br, Rb, Se (d) As, Sb, Sn

8.53 Arrange each set of atoms in order of *decreasing* IE_1 :

- (a) Na, Li, K (b) Be, F, C
(c) Cl, Ar, Na (d) Cl, Br, Se

8.54 Write the full electron configuration of the Period 2 element with the following successive IEs (in kJ/mol):

$$IE_1 = 801 \quad IE_2 = 2427 \quad IE_3 = 3659 \\ IE_4 = 25,022 \quad IE_5 = 32,822$$

8.55 Write the full electron configuration of the Period 3 element with the following successive IEs (in kJ/mol):

$$IE_1 = 738 \quad IE_2 = 1450 \quad IE_3 = 7732 \\ IE_4 = 10,539 \quad IE_5 = 13,628$$

8.56 Which element in each of the following sets would you expect to have the *highest* IE_2 ?

- (a) Na, Mg, Al (b) Na, K, Fe
(c) Sc, Be, Mg

8.57 Which element in each of the following sets would you expect to have the *lowest* IE_3 ?

- (a) Na, Mg, Al (b) K, Ca, Sc
(c) Li, Al, B

Atomic Properties and Chemical Reactivity

(Sample Problems 8.5 to 8.7)

Concept Review Questions

8.58 List three ways in which metals and nonmetals differ.

8.59 Summarize the trend in metallic character as a function of position in the periodic table. Is it the same as the trend in atomic size? The trend in ionization energy?

8.60 Explain the relationship between atomic size and reducing strength in Group 1. Explain the relationship between IE and oxidizing strength in Group 17.

8.61 Summarize the acid-base behavior of the main-group metal and nonmetal oxides in water. How does oxide acidity in water change down a group and across a period?

8.62 What ions are possible for the two largest stable elements in Group 14? How does each arise?

8.63 How are measurements of paramagnetism used to support electron configurations derived spectroscopically? Use Cu(I) and Cu(II) chlorides as examples.

8.64 The charges of a set of isoelectronic ions vary from $3+$ to $3-$. Place the ions in order of increasing size.

Skill-Building Exercises (grouped in similar pairs)

8.65 Which element would you expect to be *more* metallic?

- (a) Ca or Rb (b) Mg or Ra (c) Br or I

8.66 Which element would you expect to be *more* metallic?

- (a) S or Cl (b) In or Al (c) As or Br

8.67 Which element would you expect to be *less* metallic?

- (a) Sb or As (b) Si or P (c) Be or Na

8.68 Which element would you expect to be *less* metallic?

- (a) Cs or Rn (b) Sn or Te (c) Se or Ge

8.69 Does the reaction of a main-group nonmetal oxide in water produce an acidic or a basic solution? Write a balanced equation for the reaction of a Group 16 nonmetal oxide with water.

8.70 Does the reaction of a main-group metal oxide in water produce an acidic or a basic solution? Write a balanced equation for the reaction of a Group 2 oxide with water.

8.71 Write the charge and full ground-state electron configuration of the monatomic ion most likely to be formed by each:

- (a) Cl (b) Na (c) Ca

8.72 Write the charge and full ground-state electron configuration of the monatomic ion most likely to be formed by each:

- (a) Rb (b) N (c) Br

8.73 Write the charge and full ground-state electron configuration of the monatomic ion most likely to be formed by each:

- (a) Al (b) S (c) Sr

8.74 Write the charge and full ground-state electron configuration of the monatomic ion most likely to be formed by each:

- (a) P (b) Mg (c) Se

8.75 How many unpaired electrons are present in a ground-state atom from each of the following groups?

- (a) 2 (b) 15 (c) 18 (d) 13

8.76 How many unpaired electrons are present in a ground-state atom from each of the following groups?

- (a) 14 (b) 17 (c) 1 (d) 16

8.77 Which of these atoms are paramagnetic in their ground state?

- (a) Ga (b) Si (c) Be (d) Te

8.78 Are compounds of these ground-state ions paramagnetic?

- (a) Ti^{2+} (b) Zn^{2+} (c) Ca^{2+} (d) Sn^{2+}

8.79 Write the condensed ground-state electron configurations of these transition metal ions, and state which are paramagnetic:

- (a) V^{3+} (b) Cd^{2+} (c) Co^{3+} (d) Ag^+

8.80 Write the condensed ground-state electron configurations of these transition metal ions, and state which are paramagnetic:

- (a) Mo^{3+} (b) Au^+ (c) Mn^{2+} (d) Hf^{2+}

8.81 Palladium (Pd; $Z = 46$) is diamagnetic. Draw partial orbital diagrams to show which of the following electron configurations is consistent with this fact:

- (a) $[Kr] 5s^2 4d^8$ (b) $[Kr] 4d^{10}$ (c) $[Kr] 5s^1 4d^9$

8.82 Niobium (Nb; $Z = 41$) has an anomalous ground-state electron configuration for a Group 5 element: $[\text{Kr}] 5s^1 4d^4$. What is the expected electron configuration for elements in this group? Draw partial orbital diagrams to show how paramagnetic measurements could support niobium's actual configuration.

8.83 Rank the ions in each set in order of *increasing* size, and explain your ranking:

8.84 Rank the ions in each set in order of *decreasing* size, and explain your ranking:

Comprehensive Problems

8.85 Name the element described in each of the following:

- Smallest atomic radius in Group 16
- Largest atomic radius in Period 6
- Smallest metal in Period 3
- Highest IE_1 in Group 14
- Lowest IE_1 in Period 5
- Most metallic in Group 15
- Group 13 element that forms the most basic oxide
- Period 4 element with highest energy level filled
- Condensed ground-state electron configuration of $[\text{Ne}] 3s^2 3p^2$
- Condensed ground-state electron configuration of $[\text{Kr}] 5s^2 4d^6$
- Forms $2+$ ion with electron configuration $[\text{Ar}] 3d^3$
- Period 5 main-group element that forms a $3+$ ion
- Period 4 transition element that forms $3+$ diamagnetic ion
- Period 4 transition element that forms $2+$ ion with a half-filled d sublevel
- Heaviest lanthanide
- Period 3 element whose $2-$ ion is isoelectronic with Ar
- Alkaline earth metal whose cation is isoelectronic with Kr
- Group 15 metalloid with the most acidic oxide

8.86 Use electron configurations to account for the stability of the lanthanide ions Ce^{4+} and Eu^{2+} .

8.87 When a nonmetal oxide reacts with water, it forms an oxoacid in which the nonmetal retains the same oxidation number as in the oxide. Give the name and formula of the oxide used to prepare each of these oxoacids: (a) hypochlorous acid; (b) chlorous acid; (c) chloric acid; (d) perchloric acid; (e) sulfuric acid; (f) sulfurous acid; (g) nitric acid; (h) nitrous acid; (i) carbonic acid; (j) phosphoric acid.

8.88 A fundamental relationship of electrostatics states that the energy required to separate opposite charges of magnitudes Q_1 and Q_2 that are a distance d apart is proportional to $\frac{Q_1 \times Q_2}{d}$. Use this

relationship and any other relevant factors to explain the following:

- The IE_2 of He ($Z = 2$) is *more* than twice the IE_1 of H ($Z = 1$).
- The IE_1 of He is *less* than twice the IE_1 of H.

8.89 The energy difference between the $5d$ and $6s$ sublevels in gold accounts for its color. Assuming this energy difference is about 2.7 eV (electron volts; $1 \text{ eV} = 1.6022 \times 10^{-19} \text{ J}$), explain why gold has a warm yellow color.

8.90 Write the formula and name of the compound formed from the following ionic interactions: (a) The $2+$ ion and the $1-$ ion are both isoelectronic with the atoms of a chemically unreactive Period 4 element. (b) The $2+$ ion and the $2-$ ion are both isoelectronic with the Period 3 noble gas. (c) The $2+$ ion is the smallest with a filled d sublevel; the anion forms from the smallest halogen. (d) The ions form from the largest and smallest ionizable atoms in Period 2.

8.91 The energy changes for many unusual reactions can be determined using Hess's law (Section 6.5).

- Calculate ΔE for the conversion of $\text{F}^-(g)$ into $\text{F}^+(g)$.
- Calculate ΔE for the conversion of $\text{Na}^+(g)$ into $\text{Na}^-(g)$.

8.92 Discuss each conclusion from a study of redox reactions:

- The sulfide ion functions only as a reducing agent.
- The sulfate ion functions only as an oxidizing agent.
- Sulfur dioxide functions as an oxidizing or a reducing agent.

8.93 The hot, glowing gases around the Sun, the *corona*, can reach millions of degrees Celsius, temperatures high enough to remove many electrons from gaseous atoms. Iron ions with charges as high as $14+$ have been observed in the corona. Which ions from Fe^+ to Fe^{14+} are paramagnetic? Which would be most strongly attracted to a magnetic field?

8.94 There are some exceptions to the trends of first and successive ionization energies. For each of the following pairs, explain which ionization energy would be higher:

- IE_1 of Ga or IE_1 of Ge
- IE_2 of Ga or IE_2 of Ge
- IE_3 of Ga or IE_3 of Ge
- IE_4 of Ga or IE_4 of Ge

8.95 Use Figure 8.15 to find (a) the longest wavelength of electromagnetic (EM) radiation that can ionize an alkali metal atom; (b) the longest wavelength of EM radiation that can ionize an alkaline earth metal atom; (c) the elements, other than the alkali and alkaline earth metals, that could also be ionized by the radiation in part (b); (d) the region of the EM spectrum in which these photons are found.

8.96 Rubidium and bromine atoms are depicted at right. (a) What monatomic ions do they form? (b) What electronic feature characterizes this pair of ions, and which noble gas are they related to? (c) Which pair best represents the relative ionic sizes?

8.97 Partial (valence-level) electron configurations for four different ions are shown below:

- (a) (2+ ion)
- (b) (3+ ion)
- (c) (1+ ion)
- (d) (4+ ion)

Identify the elements from which the ions are derived, and write the formula of the oxide each ion forms.

8.98 Data from the planet Zog for some main-group elements are shown below (Zoggian units are linearly related to Earth units but are not shown). Radio signals from Zog reveal that balloonium is a monatomic gas with two positive nuclear charges. Use the data to deduce the names that Earthlings give to these elements:

Name	Atomic Radius	IE ₁	EA ₁
Balloonium	10	339	0
Inertium	24	297	+4.1
Allotropium	34	143	−28.6
Brinium	63	70.9	−7.6
Canium	47	101	−15.3
Fertilium	25	200	0
Liquidium	38	163	−46.4
Utilium	48	82.4	−6.1
Crimsonium	72	78.4	−2.9

Concepts and Skills to Review Before You Study This Chapter

- › characteristics of ionic and covalent substances (Section 2.6)
- › polar covalent bonds and the polarity of water (Section 4.1)
- › Hess's law, $\Delta H_{\text{rxn}}^\circ$, and ΔH_f° (Sections 6.5 and 6.6)
- › atomic and ionic electron configurations (Sections 8.2 and 8.4)
- › trends in atomic properties and metallic behavior (Sections 8.3 and 8.4)

Why do substances behave as they do? What accounts for the wide variation in properties of elements and compounds? Metallic sodium is soft enough to cut with a knife and has a relatively low melting point; elemental chlorine exists as diatomic molecules in the gas phase at room temperature. Combine these elements and the result is a hard, crystalline solid compound, sodium chloride, with a very high melting point (*see photo*). Why do these substances behave so differently? The answer lies in the *type of bonding within each substance*. In Chapter 8, we examined the properties of individual atoms and ions. But the behavior of matter really depends on how those atoms and ions bond.

IN THIS CHAPTER . . . We examine how atomic properties give rise to three models of chemical bonding—ionic, covalent, and metallic—and how each model explains the behavior of substances.

- › We see how metals and nonmetals combine via three types of bonding and learn how to depict atoms and ions with Lewis symbols.
- › We detail the steps in the formation of an ionic solid and focus on the importance of lattice energy.
- › Covalent bonding occurs in the vast majority of compounds, so we look at how a bond forms and discuss the relations among bond order, energy, and length.
- › We explore the relationship between bond energy and the enthalpy change of a reaction, with a focus on fuels, foods, and explosives.
- › We examine periodic trends in electronegativity and learn its role in the range of bonding, from pure covalent to ionic, and in bond polarity.
- › We consider a simple bonding model that explains the properties of metals.

9.1 ATOMIC PROPERTIES AND CHEMICAL BONDS

Just as the electron configuration and the strength of nucleus-electron attractions determine the properties of an atom, the type and strength of chemical bonds determine the properties of a substance.

The Three Ways Elements Combine

Before we examine the types of chemical bonding, we should answer a fundamental question: why do atoms bond at all? In general, *bonding lowers the potential energy between positive and negative particles* (see Figure 1.3C), whether they are oppositely charged ions or nuclei and electrons.

As you saw in Chapter 8, there is, in general, a gradation from more metallic elements to more nonmetallic elements across a period *and* up a group (Figure 9.1). Three models of bonding result from the three ways atoms of these two types of elements can combine.

B

PROPERTY	METAL ATOM	NONMETAL ATOM
Atomic size	Larger	Smaller
Z_{eff}	Lower	Higher
IE	Lower	Higher
EA	Less negative	More negative

- Each nonmetal atom holds on to its own electrons tightly (high IE) and attracts other electrons as well (highly negative EA).
- The nucleus of each atom in the bond attracts the valence electrons of the other, which draws the atoms together.

A Ionic bonding

Diagram illustrating ionic bonding. It shows a sodium atom (Na, metal) and a chlorine atom (Cl, nonmetal). An electron (e^-) is transferred from Na to Cl, resulting in a sodium cation (Na^+) and a chlorine anion (Cl^-). These ions then form an ionic solid lattice.

B Covalent bonding

Diagram illustrating covalent bonding. It shows a chlorine atom (Cl, nonmetal) and a bromine atom (Br, nonmetal). An electron is shared between them, forming a covalent bond ($Cl-Br$). Below, separate molecules of Cl_2 and Br_2 are shown.

C Metallic bonding

Diagram illustrating metallic bonding. It shows multiple sodium atoms (Na, metal). Electrons are pooled together, forming a sea of electrons (e^- sea) around the metal-ion cores.

- The shared electron pair is typically *localized* between the two atoms, linking them in a covalent bond of a particular length and strength. In most cases, separate molecules result when atoms bond covalently.
- Note that the chemical formula of a covalent substance is the *molecular formula* because it gives the actual numbers of atoms in each molecule.

3. Metal with metal: electron pooling and metallic bonding (Figure 9.2C).

We observe metals sharing their electrons, not by covalent bonding but by **metallic bonding**:

- Their atoms are relatively large, and the few outer electrons are well shielded by filled inner levels (core electrons). Thus, metals lose outer electrons easily (low IE) and do not gain them readily (slightly negative or positive EA).
- The enormous number of atoms in a sample of a metal *pool* their valence electrons in a “sea” of electrons that “flows” between and around each metal-ion core (nucleus plus inner electrons), thereby attracting and holding them together.
- Unlike the localized electrons in covalent bonding, electrons in metallic bonding are *delocalized*, moving freely throughout the entire piece of metal.

In the world of real substances, there are exceptions to these idealized models, so you can’t always predict bond type from positions of the elements in the periodic table. For example, when the metal beryllium (Group 2) combines with the nonmetal chlorine (Group 17), the bonding fits the covalent model better than the ionic model. And the ionic compound NH_4NO_3 has a polyatomic cation composed of nonmetals instead of a cation of a metallic element. Just as we see gradations in atomic behavior within a group or period, we see a *gradation in bonding from one type to another between atoms from different groups and periods* (Figure 9.3).

Figure 9.3 Gradations in bond type among Period 3 (black type) and Group 14 (red type) elements.

Lewis Symbols and the Octet Rule

Before examining each of the models in greater detail, we consider a method for depicting the valence electrons of interacting atoms that predicts how they bond. In a **Lewis electron-dot symbol** (named for the American chemist G. N. Lewis), the element symbol represents the nucleus *and* inner electrons, and dots around the symbol represent the valence electrons (Figure 9.4). Note that the pattern of dots is the same for elements within a group.

	1	2						
	ns^1	ns^2	13	14	15	16	17	18
			ns^2np^1	ns^2np^2	ns^2np^3	ns^2np^4	ns^2np^5	ns^2np^6
Period 2	• Li	• Be •	• B •	• C •	• N •	• O •	• F •	• Ne •
Period 3	• Na	• Mg •	• Al •	• Si •	• P •	• S •	• Cl •	• Ar •

Figure 9.4 Lewis electron-dot symbols for elements in Periods 2 and 3.

We use these steps to write the Lewis symbol for any main-group element:

- Find the number of valence-electron dots needed in the electron-dot symbol by noting the group number; Groups 1 and 2 elements have 1 and 2 valence electrons, respectively, while Groups 13–18 elements have 3–8 valence electrons, respectively.
- Place one dot at a time on each of the four sides (top, right, bottom, left) of the element symbol.
- Keep adding dots, pairing them, until all are used up.

The specific placement of dots is not important; that is, in addition to the one shown in Figure 9.4, the Lewis symbol for nitrogen can *also* be written as

The Lewis symbol provides information about an element’s bonding behavior:

- For a *metal*, the *total* number of dots is the number of electrons an atom loses to form a cation; for example, Mg loses two to form Mg^{2+} .

- For a *nonmetal*, the number of *unpaired* dots equals either the number of electrons an atom *gains* to form an anion (F gains one to form F^-) or the number it *shares* to form covalent bonds.

The Lewis symbol for carbon illustrates the last point. Rather than one pair of dots and two unpaired dots, as its electron configuration seems to call for ($[\text{He}] 2s^2 2p^2$), carbon has four unpaired dots because it forms four bonds. Larger nonmetals can form as many bonds as the number of dots in their Lewis symbol (Chapter 10).

In his pioneering studies, Lewis generalized much of bonding behavior into a relatively simple rule:

- **Octet rule:** *when atoms bond, they lose, gain, or share electrons to attain a filled-outer level of eight electrons (or two, for H and Li).*

The octet rule holds for nearly all of the compounds of Period 2 elements and a large number of others as well.

› Summary of Section 9.1

- › Nearly all naturally occurring substances consist of atoms or ions bonded to others. Chemical bonding allows atoms to lower their energy.
- › Ionic bonding occurs when metal atoms transfer electrons to nonmetal atoms, and the resulting ions attract each other and form an ionic solid.
- › Covalent bonding is most common between nonmetal atoms and usually results in individual molecules. Bonded atoms share one or more pairs of electrons that are localized between them.
- › Metallic bonding occurs when many metal atoms pool their valence electrons into a delocalized electron “sea” that holds all the atoms in the sample together.
- › The Lewis electron-dot symbol of a main-group atom shows valence electrons as dots surrounding the element symbol.
- › The octet rule says that, when bonding, many atoms lose, gain, or share electrons to attain a filled outer level of eight (or two) electrons.

9.2 THE IONIC BONDING MODEL

The central idea of the ionic bonding model is the *transfer of electrons from metal atoms to nonmetal atoms to form ions that attract each other and form a solid compound*. In most cases, for the main groups, the ion that forms has a filled outer level of either two or eight electrons (octet rule), the number in the nearest noble gas. In other words:

- a metal will lose the number of electrons needed to achieve the configuration of the noble gas that precedes it in the periodic table;
- a nonmetal will gain the number of electrons needed to achieve the configuration of the noble gas at the end of its period.

The transfer of an electron from a lithium atom to a fluorine atom is depicted in three ways in Figure 9.5. In each, Li loses its single outer electron and is left with a filled $n = 1$ level (two e^-), while F gains a single electron to fill its $n = 2$ level (eight e^-). In this case, each atom is one electron away from the configuration of its nearest noble gas, so the number of electrons lost by each Li equals the number gained by each F. Therefore, equal numbers of Li^+ and F^- ions form, as the formula

Figure 9.5 Three ways to depict electron transfer in the formation of Li^+ and F^- . The electron being transferred is shown in red.

LiF indicates. However, the formula of the ionic compound calcium fluoride is CaF_2 ; since Ca has two valence electrons to transfer and F gains only a single electron, two F atoms are needed to gain the two electrons lost by one Ca atom:

In Section 2.7, we found that, when writing formulas of ionic compounds, the positive charges of the cation must balance the negative charges of the anions. Now we can state that another way: in ionic bonding, *the total number of electrons lost by the metal atom(s) equals the total number of electrons gained by the nonmetal atom(s)*.

SAMPLE PROBLEM 9.1 | Depicting Ion Formation

Problem Use partial orbital diagrams and Lewis symbols to depict the formation of Na^+ and O^{2-} ions from the atoms, and give the formula of the compound formed.

Plan We write the electron configurations and we draw the orbital diagrams and Lewis symbols for Na and O atoms. To attain filled outer levels (noble gas configurations), Na loses one electron and O gains two. To make the number of electrons lost equal the number gained, two Na atoms are needed for each O atom.

Solution Na: $1s^2 2s^2 2p^6 3s^1$ or $[\text{Ne}] 3s^1$; O: $1s^2 2s^2 2p^4$ or $[\text{He}] 2s^2 2p^4$

The formula is Na_2O .

FOLLOW-UP PROBLEMS

Brief Solutions for all Follow-up Problems appear at the end of the chapter.

9.1A Use condensed electron configurations, partial orbital diagrams (ns and np only), and Lewis symbols to depict the formation of Mg^{2+} and Cl^- ions from the atoms, and give the formula of the compound formed.

9.1B Use condensed electron configurations, partial orbital diagrams (ns and np only), and Lewis symbols to depict the formation of Ca^{2+} and O^{2-} ions, and give the formula of the compound formed.

SOME SIMILAR PROBLEMS 9.20 and 9.21

Why Ionic Compounds Form: The Importance of Lattice Energy

You may be surprised to learn that energy is actually *absorbed* during electron transfer. So why does it occur? And, given this absorption of energy, why do ionic substances exist at all? As you'll see, the answer involves the enormous quantity of energy *released* after electron transfer, as the ions form a solid.

1. *The electron-transfer process.* Consider just the electron-transfer process for the formation of lithium fluoride, which involves a gaseous Li atom losing an electron and a gaseous F atom gaining it:

- The first ionization energy (IE_1) of Li is the energy absorbed when 1 mol of gaseous Li atoms loses 1 mol of valence electrons:

- The first electron affinity (EA_1) of F is the energy released when 1 mol of gaseous F atoms gains 1 mol of electrons:

- Taking the sum shows that electron transfer *by itself* requires energy:

2. *Other steps that absorb energy.* The total energy needed prior to ion formation is added to the sum of IE_1 and EA_1 : energy must be absorbed to vaporize metallic Li to gaseous Li atoms (161 kJ/mol), and energy must be absorbed to break the bond in F_2 molecules to produce separate F atoms (79.5 kJ/mol).

3. *Steps that release energy.* Despite these endothermic steps, the standard enthalpy of formation (ΔH_f°) of solid LiF is -617 kJ/mol ; that is, 617 kJ is *released* when 1 mol of LiF(s) forms from its elements. Formation of LiF is typical of reactions between active metals and nonmetals: ionic solids form readily (Figure 9.6).

Figure 9.6 The exothermic formation of sodium bromide. **A**, Sodium (in beaker under mineral oil) and bromine. **B**, The reaction is rapid and vigorous.

Source: Stephen Frisch/McGraw Hill

If the overall reaction releases energy, there must be some step that is exothermic enough to outweigh the endothermic steps. This step involves the *strong attraction between pairs of oppositely charged ions*.

When 1 mol of $Li^+(g)$ and 1 mol of $F^-(g)$ coalesce into a crystalline solid in which each ion attracts several oppositely charged ions, a large quantity of energy is released:

The negative of this enthalpy change is 1050 kJ, the lattice energy of LiF. The **lattice energy** ($\Delta H_{\text{lattice}}^\circ$) is the enthalpy change that accompanies the reverse of the process in the previous equation—1 mol of ionic solid separating into gaseous ions:

Determining Lattice Energy with a Born-Haber Cycle The magnitude of the lattice energy is a measure of the strength of the ionic interactions and influences macroscopic properties, such as melting point, hardness, and solubility. Despite playing this crucial role in the formation of ionic compounds, lattice energy is usually *not* measured directly. One way to determine it applies Hess's law (see Section 6.5) in a **Born-Haber cycle**, a series of steps from elements to ionic solid for which all the enthalpies* are known except the lattice energy.

Let's go through a Born-Haber cycle for the formation of lithium fluoride to calculate $\Delta H_{\text{lattice}}^\circ$. Figure 9.7 shows two possible paths, a direct combination reaction (ΔH_f° ; *black arrow*) and a multistep path (*orange arrows*) in which one step is the unknown $\Delta H_{\text{lattice}}^\circ$. Hess's law tells us both paths involve the same overall enthalpy change:

$$\Delta H_f^\circ \text{ of LiF(s)} = \text{sum of } \Delta H^\circ \text{ values for multistep path}$$

*Strictly speaking, ionization energy (IE) and electron affinity (EA) are internal energy changes (ΔE), not enthalpy changes (ΔH), but in these steps, $\Delta H = \Delta E$ because $\Delta V = 0$ (Section 6.2).

Figure 9.7 The Born-Haber cycle for lithium fluoride. The formation of LiF(s) from its elements can happen in one combination reaction (*black arrow*) or in five steps (*orange arrows*). The unknown enthalpy change is $\Delta H^\circ_{\text{step 5}}$ ($-\Delta H^\circ_{\text{lattice}}$ of LiF).

We identify each ΔH° by its step number in Figure 9.7:

Step	Chemical Equation	Energy (ΔH°) Value
1. From solid Li to gaseous Li (sublimation): breaking metallic bonds and vaporizing the atoms	$\text{Li(s)} \rightarrow \text{Li(g)}$	$\Delta H^\circ_{\text{step 1}} = 161 \text{ kJ}$
2. From F_2 molecules to F atoms: breaking the covalent bond in F_2 (bond energy, BE); production of 1 mol of LiF requires $\frac{1}{2}$ mol of F_2	$\frac{1}{2} \text{F}_2(\text{g}) \rightarrow \text{F(g)}$	$\Delta H^\circ_{\text{step 2}} = \frac{1}{2}(\text{BE of F}_2)$ $= \frac{1}{2}(159 \text{ kJ})$ $= 79.5 \text{ kJ}$
3. From Li to Li^+ : remove the 2s electron.	$\text{Li(g)} \rightarrow \text{Li}^+(\text{g}) + \text{e}^-$	$\Delta H^\circ_{\text{step 3}} = \text{IE}_1 = 520 \text{ kJ}$
4. From F to F^- : add an electron	$\text{F(g)} + \text{e}^- \rightarrow \text{F}^-(\text{g})$	$\Delta H^\circ_{\text{step 4}} = \text{EA}_1 = -328 \text{ kJ}$
5. From gaseous ions to ionic solid ($-\Delta H^\circ_{\text{lattice}}$)	$\text{Li}^+(\text{g}) + \text{F}^-(\text{g}) \rightarrow \text{LiF(s)}$	$\Delta H^\circ_{\text{step 5}} = ?$
Overall reaction (combination reaction):	$\text{Li(s)} + \frac{1}{2} \text{F}_2(\text{g}) \rightarrow \text{LiF(s)}$	$\Delta H^\circ_{\text{f}} = -617 \text{ kJ}$

According to Hess's law:

$$\Delta H^\circ_{\text{f}} = \Delta H^\circ_{\text{step 1}} + \Delta H^\circ_{\text{step 2}} + \Delta H^\circ_{\text{step 3}} + \Delta H^\circ_{\text{step 4}} + \Delta H^\circ_{\text{step 5}}$$

Solving for $\Delta H^\circ_{\text{step 5}}$ gives

$$\begin{aligned} \Delta H^\circ_{\text{step 5}} &= \Delta H^\circ_{\text{f}} - (\Delta H^\circ_{\text{step 1}} + \Delta H^\circ_{\text{step 2}} + \Delta H^\circ_{\text{step 3}} + \Delta H^\circ_{\text{step 4}}) \\ &= -617 \text{ kJ} - [161 \text{ kJ} + 79.5 \text{ kJ} + 520 \text{ kJ} + (-328 \text{ kJ})] \\ &= -1050 \text{ kJ} \end{aligned}$$

Since $\Delta H^\circ_{\text{step 5}} = -\Delta H^\circ_{\text{lattice}}$, $-(-1050 \text{ kJ}) = 1050 \text{ kJ} = \Delta H^\circ_{\text{lattice}}$.

Note that *the lattice energy is, by far, the largest component of the multistep process.* (Problems 9.30 and 9.31 are among several that focus on Born-Haber cycles.)

The Born-Haber cycle shows that the energy *required* for elements to form ions is *supplied* by the attraction among the ions in the solid. And the “take-home lesson” is that *ionic solids exist only because the lattice energy far exceeds the total energy needed to form the ions.*

Periodic Trends in Lattice Energy

The lattice energy results from electrostatic interactions among ions, so its magnitude depends on ionic size, ionic charge, and the arrangement of the ions in the solid. Therefore, we expect to see periodic trends in lattice energy.

Explaining the Trends with Coulomb's Law Coulomb's law states that the electrostatic energy between particles A and B is directly proportional to the product of their charges and inversely proportional to the distance between them:

$$\text{Electrostatic energy} \propto \frac{\text{charge A} \times \text{charge B}}{\text{distance}}$$

Lattice energy is directly proportional to electrostatic energy. In an ionic solid, cations and anions lie as close to each other as possible, so the distance between them is the sum of the ionic radii (see Figure 8.25):

$$\text{Electrostatic energy} \propto \frac{\text{cation charge} \times \text{anion charge}}{\text{cation radius} + \text{anion radius}} \propto \Delta H_{\text{lattice}}^{\circ} \quad (9.1)$$

Figure 9.8 The effects of ionic size and ionic charge on the magnitude of lattice energy.

This relationship helps us explain the effects of ionic size and charge on trends in lattice energy (Figure 9.8):

1. *Effect of ionic size.* Smaller ions attract each other more strongly than larger ions, because the charges are closer to each other. As we move down a group, ionic radii increase, so the electrostatic energy between cations and anions decreases; thus, lattice energies should decrease as well:

ionic size increases $\uparrow$, lattice energy decreases $\downarrow$

Figure 9.9 shows that, for the alkali-metal halides, lattice energy decreases down the group whether the cation remains the same (LiF to LiI) or the anion remains the same (LiF to RbF).

Figure 9.9 Trends in lattice energy. The lattice energies are shown for compounds formed from a given Group 1 cation (*left side*) and one of the Group 17 anions (*bottom*). LiF (smallest ions) has the highest lattice energy, and RbI (largest ions) has the lowest.

2. *Effect of ionic charge.* Ions with higher charges attract each other more strongly than ions with lower charges; thus, lattice energy increases with increasing ionic charge:

ionic charge increases $\uparrow$, lattice energy increases $\uparrow$

Across a period, ionic charge changes. For example, lithium fluoride and magnesium oxide have cations and anions of about equal radii ($\text{Li}^+ = 76 \text{ pm}$ and $\text{Mg}^{2+} = 72 \text{ pm}$; $\text{F}^- = 133 \text{ pm}$ and $\text{O}^{2-} = 140 \text{ pm}$). The major difference is between singly charged Li^+ and F^- ions and doubly charged Mg^{2+} and O^{2-} ions. The difference in the lattice energies of the two compounds is striking:

$$\Delta H^\circ_{\text{lattice}} \text{ of LiF} = 1050 \text{ kJ/mol} \quad \text{and} \quad \Delta H^\circ_{\text{lattice}} \text{ of MgO} = 3923 \text{ kJ/mol}$$

This nearly fourfold increase in $\Delta H^\circ_{\text{lattice}}$ reflects the fourfold increase in the product of the charges (1×1 vs. 2×2) in the numerator of Equation 9.1.

Student Hot Spot

Student data indicate that you may struggle with predicting relative lattice energies of ionic compounds. Access the eBook to view an additional Learning Resource video on this topic.

SAMPLE PROBLEM 9.2

Predicting Relative Lattice Energy from Ionic Properties

Problem Use ionic properties to explain which compound in each pair has the larger lattice energy: (a) RbI or NaBr; (b) KCl or CaS.

Plan To choose the compound with the larger lattice energy, we apply Coulomb's law and periodic trends in ionic radius and charge. We examine the ions in each compound: for ions of similar size, higher charge leads to a larger lattice energy; for ions with the same charge, smaller size leads to larger lattice energy because the ions can get closer together.

Solution (a) **NaBr.** All the ions have single charges, so charge is not a factor. Size increases down a group, so Rb^+ is larger than Na^+ , and I^- is larger than Br^- . Therefore, NaBr has the larger lattice energy because it consists of smaller ions.

(b) **CaS.** Size decreases from left to right across a period, so K^+ is slightly larger than Ca^{2+} , and S^{2-} is slightly larger than Cl^- . However, these small differences are not nearly as important as the charges: Ca^{2+} and S^{2-} have twice the charge of K^+ and Cl^- , so CaS has the larger lattice energy.

Check The actual lattice energies are (a) RbI = 598 kJ/mol and NaBr = 719 kJ/mol; (b) KCl = 676 kJ/mol and CaS = 3039 kJ/mol.

FOLLOW-UP PROBLEMS

9.2A Use ionic properties to explain which compound has the *smaller* lattice energy: BaF_2 or SrF_2 .

9.2B Use ionic properties to arrange the following compounds in order of *increasing* lattice energy: MgF_2 , Na_2O , CaO .

SOME SIMILAR PROBLEMS 9.26–9.29

Why Does MgO Exist? We might ask how ionic solids, like MgO, with doubly charged ions, could even form. After all, forming 1 mol of Mg^{2+} involves the sum of the first *and* second ionization energies:

And, whereas forming 1 mol of O^- ions is exothermic (first electron affinity, EA_1), adding a second mole of electrons (second electron affinity, EA_2) is endothermic because the electron is added to a negative ion. The overall formation of O^{2-} ions is endothermic:

There are also the endothermic steps for converting Mg(s) to Mg(g) (148 kJ/mol) and breaking $\frac{1}{2}$ mol of O_2 molecules into O atoms ($\frac{1}{2}[498 \text{ kJ/mol}] = 249 \text{ kJ}$). Thus, the total energy that must be absorbed in the formation of the compound is significant: $2188 + 737 + 148 + 249 \text{ kJ} = 3322 \text{ kJ}$. Nevertheless, the 2+ and 2- ionic charges make the lattice energy so large ($\Delta H^\circ_{\text{lattice}} = 3923 \text{ kJ/mol}$) that MgO forms readily whenever Mg burns in air ($\Delta H^\circ_f = -601 \text{ kJ/mol}$; Figure 3.6).

Figure 9.10 Why ionic compounds crack. **A**, Ionic compounds crack when struck with enough force. **B**, When a force moves like charges near each other, repulsions cause a crack.

Source: (A) Stephen Frisch/McGraw Hill

How the Model Explains the Properties of Ionic Compounds

The central role of any model is to explain the facts. With atomic-level views, we can see how the ionic bonding model accounts for the properties of ionic solids.

1. *Physical behavior.* As a typical ionic compound, a piece of rock salt (NaCl) is *hard* (does not dent), *rigid* (does not bend), and *brittle* (cracks without deforming). These properties arise from the strong attractive forces that hold the ions *in specific positions*. Moving them out of position requires overcoming these forces, so rock salt does not dent or bend. If enough force *is* applied, ions of like charge are brought next to each other, and repulsions between them crack the sample suddenly (Figure 9.10).

2. *Electrical conductivity.* Ionic compounds typically *do not* conduct electricity in the solid state but *do* conduct when melted or dissolved. According to the model, the solid consists of fixed ions, which cannot move out of position, but when the solid melts or dissolves, the ions can move and carry a current (Figure 9.11).

3. *Melting and boiling point.* Large amounts of energy are needed to free the ions from their positions and separate them. Thus, we expect ionic compounds to have high melting points and much higher boiling points (Table 9.1). In fact, the interionic

Figure 9.11 Electrical conductivity and ion mobility.

Source: Stephen Frisch/McGraw Hill

attraction is so strong that a vaporized ionic compound consists of **ion pairs**, gaseous ionic molecules, rather than individual ions (Figure 9.12). In their normal state, as you know, *ionic compounds are solid arrays of ions, and no separate molecules exist.*

Summary of Section 9.2

- › In ionic bonding, a metal transfers electrons to a nonmetal, and the resulting ions attract each other to form a solid.
- › Main-group elements often attain a filled outer level (either eight electrons or two electrons) by forming ions that have the electron configuration of the nearest noble gas.
- › Ion formation by itself *absorbs* energy, but more than that quantity of energy is *released* when the ions form a solid. The high lattice energy of an ionic solid, the energy required to separate the solid into gaseous ions, is the reason the compound forms.
- › The lattice energy is determined by applying Hess's law in a Born-Haber cycle.
- › Lattice energies increase with higher ionic charge and decrease with larger ionic radius (Coulomb's law).
- › According to the ionic bonding model, the strong electrostatic attractions that keep ions in position explain why ionic solids are hard, conduct a current only when melted or dissolved, and have high melting and boiling points.
- › Ion pairs form when an ionic compound vaporizes.

Table 9.1 Melting and Boiling Points of Some Ionic Compounds		
Compound	mp (°C)	bp (°C)
CsBr	636	1300
NaI	661	1304

9.3 THE COVALENT BONDING MODEL

The number of covalent compounds dwarfs the number of ionic compounds. Covalent substances range from diatomic hydrogen to biological and synthetic macromolecules with many thousands of atoms and even to some minerals that have covalent bonds throughout the sample. And covalent bonds occur in all polyatomic ions, too. Without doubt, *sharing electrons is the main way that atoms interact.*

The Formation of a Covalent Bond

Why does hydrogen gas consist of H₂ molecules and not separate H atoms? Figure 9.13 plots the potential energy of a system of two isolated H atoms versus the distance

Figure 9.13 Covalent bond formation in H₂. The energy difference between points 1 and 3 is the H₂ bond energy (432 kJ/mol). The internuclear distance at point 3 is the H₂ bond length (74 pm).

Figure 9.14 Distribution of electron density in H_2 . **A**, Electron density (blue shading) is high around and between the nuclei. Electron density doubles with each concentric curve. **B**, The highest regions of electron density are shown as peaks.

between their nuclei (see also Figure 2.17). Let's start at the right end of the curve and move along it to the left, as the atoms get closer:

- At point 1, the atoms are far apart, and each acts as though the other were not present.
- At point 2, the distance between the atoms has decreased enough for each nucleus to start attracting the other atom's electron, which lowers the potential energy. As the atoms get closer, these attractions increase, but so do repulsions between the nuclei and between the electrons.
- At point 3 (bottom of the energy "well"), the maximum attraction is achieved in the face of the increasing repulsion, and the system has its minimum energy.
- At point 4, if it were reached, the atoms would be too close, and the rise in potential energy from increasing repulsions between the nuclei and between the electrons would push them apart toward point 3 again.

Thus, a **covalent bond** arises from the balance between the nuclei attracting the electrons and electrons and nuclei repelling each other, as shown in the blow-up of the structure at point 3. (We'll return to Figure 9.13 shortly.)

*Formation of a covalent bond always results in greater electron density **between** the nuclei.* Figure 9.14 depicts this fact with an *electron density contour map* (A) and an *electron density relief map* (B).

Bonding Pairs and Lone Pairs

Unlike ionic compounds in which atoms gain or lose enough electrons to obtain an octet of electrons, atoms in covalent compounds share electrons. To achieve a full outer (valence) level of electrons, *each atom in a covalent bond "counts" the shared electrons as belonging entirely to itself.* Thus, the two shared electrons in H_2 simultaneously fill the outer level of *both* H atoms, as clarified by the blue circles. The **bonding pair**, or **shared pair**, is represented by a pair of dots or a line.

An outer-level electron pair that is *not* involved in bonding is called a **lone pair**, or **unshared pair**. The bonding pair in HF fills the outer level of the H atom *and*, together with three lone pairs, fills the outer level of the F atom as well. In F_2 , the bonding pair and three lone pairs fill the outer level of *each* F atom so that each has an octet of electrons. (This text generally shows bonding pairs as lines and lone pairs as dots.)

Properties of a Covalent Bond: Order, Energy, and Length

A covalent bond has three important properties that are closely related to one another and to the compound's reactivity—bond order, bond energy, and bond length.

1. **Bond order.** The **bond order** is the number of electron pairs being shared by a given pair of atoms:

- A **single bond**, as shown in H_2 , HF, or F_2 in the previous subsection, is the most common bond and consists of one bonding pair of electrons: *a single bond has a bond order of 1.*
- Many molecules (and ions) contain *multiple bonds*, in which more than one pair is shared between two atoms. Multiple bonds usually involve C, O, and/or N atoms. A **double bond** consists of two bonding electron pairs, four electrons shared

between two atoms, so *the bond order is 2*. Ethylene (C_2H_4) contains a carbon-carbon double bond and four carbon-hydrogen single bonds. *Each carbon “counts” the four electrons in the double bond and the four in its two single bonds to hydrogen atoms to attain an octet.*

- A **triple bond** consists of three shared pairs: two atoms share six electrons, so *the bond order is 3*. The N_2 molecule has a triple bond, and each N atom also has a lone pair. Six shared and two unshared electrons give *each* N atom an octet.

2. **Bond energy.** The strength of a covalent bond depends on the magnitude of the attraction between the nuclei and shared electrons. The **bond energy (BE)** (also called *bond enthalpy* or *bond strength*) is the energy needed to overcome this attraction and is defined as *the standard enthalpy change for breaking the bond in 1 mol of gaseous molecules*. Bond breakage is an *endothermic* process, so *bond energy is always positive*:

The bond energy is the difference in energy between separated and bonded atoms (the potential energy difference between points 1 and 3—the energy “well”—in Figure 9.13). *The same quantity of energy absorbed to break the bond is released when the bond forms.* Bond formation is an *exothermic* process, so *the sign of its enthalpy change is always negative*:

Table 9.2 lists the energies of some common bonds. By definition,

- *Stronger bonds have a larger BE because they are lower in energy (have a deeper energy well).*
- *Weaker bonds have a smaller BE because they are higher in energy (have a shallower energy well).*

The energy of a given bond varies slightly from molecule to molecule and even within the same molecule, so each value is an *average* bond energy. In other words, the C—H bond energy value of 413 kJ/mol is the average of the C—H bond energy values in all molecules containing this bond.

Table 9.2 | Average Bond Energies (kJ/mol) and Bond Lengths (pm)

Figure 9.15 Bond length and covalent radius.

3. **Bond length.** A covalent bond has a **bond length**, the distance between the nuclei of the two bonded atoms. In Figure 9.13, bond length is the distance between the nuclei at the point of minimum energy (bottom of the well), and Table 9.2 shows the lengths of some covalent bonds. Like bond energies, these values are *average* bond lengths for a bond in different substances. Bond length is related to the sum of the radii of the bonded atoms. In fact, most atomic radii are calculated from measured bond lengths (see Figure 8.11C). Bond lengths for a series of similar bonds, as in the halogens, increase with atomic size (Figure 9.15).

The order, energy, and length of a covalent bond are interrelated. Two nuclei are more strongly attracted to two shared electron pairs than to one, so double-bonded atoms are drawn closer together *and* are more difficult to pull apart than single-bonded atoms. Therefore, *for a given pair of atoms*,

- A higher bond order results in a smaller bond length. As bond order increases, bond length decreases.
- A higher bond order results in a higher bond energy. As bond order increases, bond energy also increases.

Thus, as Table 9.3 shows, for a given pair of atoms, *a shorter bond is a stronger bond*.

In some cases, we can see a relation among atomic size, bond length, and bond energy by varying one of the atoms involved in a single bond while holding the other constant:

- *Variation within a group.* The trend in carbon-halogen single bond lengths, $\text{C—I} > \text{C—Br} > \text{C—Cl} > \text{C—F}$, parallels the trend in atomic size, $\text{I} > \text{Br} > \text{Cl} > \text{F}$, and is opposite to the trend in bond energy, $\text{C—F} > \text{C—Cl} > \text{C—Br} > \text{C—I}$.
- *Variation within a period.* Looking again at single bonds involving carbon, the trend in bond lengths, $\text{C—N} > \text{C—O} > \text{C—F}$, parallels the trend in atomic size, $\text{N} > \text{O} > \text{F}$, and is opposite to the trend in bond energy, $\text{C—F} > \text{C—O} > \text{C—N}$.

In general, bond length increases (and bond energy decreases) with increasing atomic radii of the atoms in the bond.

Table 9.3 | The Relation of Bond Order, Bond Length, and Bond Energy

Bond	Bond Order	Average Bond Length (pm)	Average Bond Energy (kJ/mol)
C—O	1	143	385
C=O	2	123	748
$\text{C}\equiv\text{O}$	3	113	1077
C—C	1	154	370
C=C	2	134	602
$\text{C}\equiv\text{C}$	3	121	839
N—N	1	146	277
N=N	2	122	418
$\text{N}\equiv\text{N}$	3	110	945

SAMPLE PROBLEM 9.3 | Comparing Bond Length and Bond Strength

Problem Without referring to Table 9.2, rank the bonds in each set in order of *decreasing* bond length and *decreasing* bond strength:

- (a) S—F , S—Br , S—Cl (b) C=N , C—N , C=O

Plan (a) S is singly bonded to three different halogen atoms, so the bond order is the same. Bond length increases and bond strength decreases as the halogen's atomic radius increases. (b) To compare the single and double bonds involving N, recall that bond strength increases and bond length decreases as bond order increases. To compare the two double bonds, recall that bond length increases and bond strength decreases as the atomic radius increases.

Solution (a) Atomic size increases down a group, so $\text{F} < \text{Cl} < \text{Br}$.

Bond length: $\text{S—Br} > \text{S—Cl} > \text{S—F}$

Bond strength: $\text{S—F} > \text{S—Cl} > \text{S—Br}$

(b) Atomic size decreases across a period, so $N > O$ in size; therefore the $C=N$ bond is longer than the $C=O$ bond. The $C-N$ bond is longer than the $C=N$ bond since bond length decreases with increasing bond order. Thus,

Bond length: $C-N > C=N > C=O$

Bond strength: $C=O > C=N > C-N$

Check From Table 9.2, we see that the rankings are correct.

How the Model Explains the Properties of Covalent Substances

The covalent bonding model proposes that electron sharing between pairs of atoms leads to *strong, localized bonds*. Most, but not all, covalent substances consist of individual molecules. These *molecular* covalent substances have very different *physical* properties than *network* covalent solids do, because different types of forces give rise to the two kinds of substances.

1. *Physical properties of molecular covalent substances.* At first glance, the model seems inconsistent with physical properties of covalent substances. Most are gases (such as methane and ammonia), liquids (such as benzene and water), or low-melting solids (such as sulfur and paraffin wax). If covalent bonds are so strong (~ 200 to 500 kJ/mol), why do covalent substances melt and boil at such low temperatures? To answer this, we'll focus on two different forces:

- (1) *strong bonding forces* hold the atoms together *within* the molecule, and
- (2) *weak intermolecular forces* act *between* separate molecules in the sample.

It is the weak forces *between* one molecule and the other molecules around it that account for the physical properties of *molecular* covalent substances. For example, look what happens when pentane (C_5H_{12}) boils (Figure 9.16): weak forces *between* pentane molecules are overcome during this process; the strong $C-C$ and $C-H$ covalent bonds *within* each pentane molecule are *not* broken.

2. *Physical properties of network covalent solids.* Some covalent substances do not consist of separate molecules. Rather, these *network covalent solids* are held together by covalent bonds *between atoms throughout the sample*, and their properties *do* reflect the strength of covalent bonds. Two examples are quartz and diamond (Figure 9.17). Quartz (SiO_2 ; *top*) has silicon-oxygen covalent bonds in three dimensions; no separate SiO_2 molecules exist. It is very hard and melts at $1550^\circ C$. Diamond (*bottom*) has covalent bonds connecting each carbon atom to four others. It is the hardest natural substance known and melts at around $3550^\circ C$. Thus, covalent bonds *are* strong, but most covalent substances consist of separate molecules with weak forces between them. (We discuss intermolecular forces in detail in Chapter 12.)

3. *Electrical conductivity.* An electric current is carried by either mobile electrons or mobile ions. Most covalent substances are poor electrical conductors, whether melted or dissolved, because their electrons are localized as either shared or unshared pairs and are not mobile, and no ions are present.

The Tools of the Laboratory essay describes a technique used widely for studying the types of bonds in covalent substances.

Figure 9.16 Strong forces within molecules and weak forces between them.

Source: Stephen Frisch/McGraw Hill

Figure 9.17 Covalent bonds of network covalent solids: quartz and diamond.

Infrared (IR) spectroscopy is an instrumental technique most often used to study covalently bonded molecules. The key components of an IR spectrometer are the same as those of other types of spectrometers (see Figure B7.3). The source emits radiation of many wavelengths, but only those in the IR region are selected. The sample is typically a pure liquid or solid that absorbs varying amounts of different IR wavelengths. An IR spectrum consists of peaks that indicate these various absorptions.

Molecular Vibrations and IR Absorption

In addition to moving through space and rotating about several axes, the molecules in a sample also undergo vibrations between bonded atoms: each pair of atoms is vibrating as though the bonds were springs that stretch and bend, as shown in Figure B9.1 for some diatomic and triatomic molecules; larger molecules vibrate in many more ways.

Each vibration has an energy and frequency based on the type of motion, masses of the atoms, and strength of the bond. These vibrational energies and frequencies correspond to IR wavelengths between 2.5 and 25 μm . Just as an atom can absorb a photon whose energy equals the difference between *electron* energy levels, a molecule can absorb an IR photon whose energy equals the difference between *vibrational* energy levels. The result is an IR spectrum that consists of peaks that indicate the various absorptions.

Compound Identification

An IR spectrum can be used to identify a compound:

1. *Each kind of bond absorbs a specific range of wavelengths.* That is, a C—C bond absorbs a different range than does a C=C bond, a C—H bond, a C=O bond, and so forth.
2. *Each compound has a unique spectrum.* The IR spectrum acts as a fingerprint to identify the compound, because the quantity of each wavelength absorbed depends on the detailed molecular structure. For example, no other compound has the IR spectrum of acrylonitrile, a compound used to make plastics (Figure B9.2).

Problems

B9.1 In Figure B9.2, the peak labeled “C=C stretch” occurs at a shorter wavelength (higher wavenumber) than that labeled “C—C stretch,” as it does in the IR spectrum of any substance with those bonds. Explain the relative positions of these peaks. In what relative position along the wavelength scale of Figure B9.2 would you expect to find a peak for a C≡C stretch? Explain.

Figure B9.1 Vibrational motions in general diatomic and triatomic molecules.

B9.2 Atmospheric CO_2 absorbs IR radiation and re-emits it, thus warming the atmosphere. The vibrations of a CO_2 molecule are symmetrical stretch, bend, and asymmetrical stretch (see Figure B9.1), with frequencies of $4.02 \times 10^{13} \text{ s}^{-1}$, $2.00 \times 10^{13} \text{ s}^{-1}$, and $7.05 \times 10^{13} \text{ s}^{-1}$, respectively.

- (a) What wavelengths correspond to these vibrations?
- (b) Calculate the energy (in J) of each vibration. Which uses the least energy?

Figure B9.2 The infrared (IR) spectrum of acrylonitrile. In this typical IR spectrum, many absorption bands appear as downward-projecting “peaks” of differing depths and sharpness. Most correspond to a particular type of vibration (stretch, bend, rock, wag, or twist). Some broad peaks (e.g., “combination band”) represent several overlapping vibrations. The bottom axis identifies the wavenumber, the inverse of wavelength, which has the unit cm^{-1} . (The scale expands to the right of 2000 cm^{-1} .)

› Summary of Section 9.3

- › A shared, localized pair of valence electrons holds the nuclei of two atoms together in a covalent bond, filling each atom’s outer level.
- › Bond order is the number of shared pairs between two atoms. Bond energy (strength) is the energy absorbed to separate the atoms; the same quantity of energy is released when the bond forms. Bond length is the distance between the nuclei of the two atoms.
- › For a given pair of atoms, bond order is directly related to bond energy and inversely related to bond length.
- › Molecular covalent substances are soft and low melting because of the weak forces *between* the molecules, not the strong bonding forces *within* them. Network covalent solids are hard and high melting because covalent bonds join all the atoms in the sample.
- › Most covalent substances have low electrical conductivity because their electrons are localized and ions are absent.
- › Atoms in a covalent bond vibrate, and the energies of these vibrations are studied with IR spectroscopy.

9.4 BOND ENERGY AND CHEMICAL CHANGE

The relative strengths of the bonds in reactants and products determine whether heat is released or absorbed in a chemical reaction. In Chapter 20, you’ll see that the change in bond energy is one of two factors determining whether the reaction occurs at all. In this section, we’ll discuss the origin of the enthalpy of reaction, use bond energies to calculate it, and look at the energy available from fuels, foods, and explosives.

Changes in Bond Energy: Where Does $\Delta H_{\text{rxn}}^\circ$ Come From?

In Chapter 6, we discussed the heat involved in a chemical change but never asked a central question: where does the enthalpy of reaction ($\Delta H_{\text{rxn}}^\circ$) come from?

For example, when 1 mol of H_2 and 1 mol of F_2 react to form 2 mol of HF at 1 atm and 298 K,

where does the 546 kJ that is released come from? We find the answer by looking closely at the energies of the molecules involved. A system's total internal energy is composed of its kinetic energy and potential energy. Let's see how these change during the formation of HF :

- **Kinetic energy.** The most important contributions to kinetic energy are the molecules' movements through space and their rotations and vibrations. However, since kinetic energy is proportional to temperature, which is constant at 298 K, it shows no net change during this formation reaction.
- **Potential energy.** The most important contributions to potential energy are phase changes and changes in the attraction between vibrating atoms, between nucleus and electrons (and between electrons) in each atom, between protons and neutrons in each nucleus, and between nuclei and the shared electron pair in each bond. In this reaction, there are no phase changes, vibrational forces vary only slightly as the bonded atoms change, and forces within the atoms and nuclei don't change at all. The only major change in potential energy comes from changes in the attraction between the nuclei and the shared electron pair—the bond energies—of H_2 , F_2 , and HF .

Thus, our answer to “where does $\Delta H^\circ_{\text{rxn}}$ come from?” is that it doesn't really “come from” anywhere: *the heat released or absorbed during a chemical change is due to differences between reactant bond energies and product bond energies.*

Using Bond Energies to Calculate $\Delta H^\circ_{\text{rxn}}$

Recall that Hess's law (Section 6.5) allows us to think of any reaction as a two-step process, whether or not it actually occurs that way:

1. A certain quantity of heat is absorbed ($\Delta H^\circ > 0$) to break the reactant bonds and form separate atoms.
2. A different quantity of heat is then released ($\Delta H^\circ < 0$) when the atoms form product bonds.

The sum (symbolized by Σ) of these enthalpy changes is the enthalpy of reaction, $\Delta H^\circ_{\text{rxn}}$:

$$\Delta H^\circ_{\text{rxn}} = \Sigma \Delta H^\circ_{\text{reactant bonds broken}} + \Sigma \Delta H^\circ_{\text{product bonds formed}} \quad (9.2)$$

- In an exothermic reaction, the energy released during the formation of bonds in the product molecules is *greater* than the energy required to break bonds in the reactant molecules; the magnitude of $\Delta H^\circ_{\text{product bonds formed}}$ is greater than that of $\Delta H^\circ_{\text{reactant bonds broken}}$, so the sum, $\Delta H^\circ_{\text{rxn}}$, is *negative* (heat is released).
- In an endothermic reaction, the opposite situation is true: the energy released during bond formation in the product molecules is *smaller* than the energy required to break bonds in the reactant molecules; the magnitude of $\Delta H^\circ_{\text{product bonds formed}}$ is smaller than that of $\Delta H^\circ_{\text{reactant bonds broken}}$, so $\Delta H^\circ_{\text{rxn}}$ is *positive* (heat is absorbed).

An equivalent form of Equation 9.2 uses bond energies:

$$\Delta H^\circ_{\text{rxn}} = \Sigma \text{BE}_{\text{reactant bonds broken}} - \Sigma \text{BE}_{\text{product bonds formed}}$$

(We need the minus sign because all bond energies are positive.)

In reality, only certain bonds break and form during a typical reaction, but we can apply Hess's law and use the following simpler method for calculating $\Delta H^\circ_{\text{rxn}}$:

1. Break *all* the reactant bonds to obtain individual atoms.
2. Use the atoms to form *all* the product bonds.
3. Add the bond energies, with appropriate signs, to obtain the enthalpy of reaction.

(This method assumes reactants and products do not change physical state; additional heat is involved when phase changes occur. We address this topic in Chapter 12.)

Let's use the method to calculate $\Delta H_{\text{rxn}}^\circ$ for two reactions:

1. *Formation of HF.* When 1 mol of H—H bonds and 1 mol of F—F bonds absorb energy and break, the 2 mol of H atoms and 2 mol of F atoms form 2 mol of H—F bonds, which releases energy. We find the bond energy values in Table 9.2 and use a positive sign for bonds broken and a negative sign for bonds formed:

Bonds broken	$\Delta H_{\text{reactant bonds broken}}^\circ$	Bonds formed	$\Delta H_{\text{product bonds formed}}^\circ$
1 $\times$ H—H	(1 mol)(436 kJ/mol) = 436 kJ	2 $\times$ H—F	(2 mol)(−570 kJ/mol) = −1140 kJ
1 $\times$ F—F	(1 mol)(159 kJ/mol) = 159 kJ		
$\Sigma \Delta H_{\text{reactant bonds broken}}^\circ = 595 \text{ kJ}$		$\Sigma \Delta H_{\text{product bonds formed}}^\circ = -1140 \text{ kJ}$	

Applying Equation 9.2 gives

$$\begin{aligned} \Delta H_{\text{rxn}}^\circ &= \Sigma \Delta H_{\text{reactant bonds broken}}^\circ + \Sigma \Delta H_{\text{product bonds formed}}^\circ \\ &= 595 \text{ kJ} + (-1140 \text{ kJ}) = -545 \text{ kJ} \end{aligned}$$

The small discrepancy between this value (−545 kJ) and the value from tabulated ΔH_f° values (−547 kJ) is due to variations in experimental method.

2. *Combustion of CH₄.* For this more complicated reaction, we assume that all the bonds in CH₄ and O₂ break, and the atoms form all the bonds in CO₂ and H₂O (Figure 9.18):

Once again, we use Table 9.2 and appropriate signs for bonds broken and bonds formed:

Bonds broken	$\Delta H^\circ_{\text{reactant bonds broken}}$	Bonds formed	$\Delta H^\circ_{\text{product bonds formed}}$
4 × C—H	(4 mol)(413 kJ/mol) = 1652 kJ	2 × C=O	(2 mol)(−532 kJ/mol) = −1064 kJ
2 × O=O	(2 mol)(498 kJ/mol) = 996 kJ	4 × O—H	(4 mol)(−497 kJ/mol) = −1988 kJ
$\Sigma \Delta H^\circ_{\text{reactant bonds broken}} = 2648 \text{ kJ}$		$\Sigma \Delta H^\circ_{\text{product bonds formed}} = -3052 \text{ kJ}$	

Applying Equation 9.2 gives

$$\begin{aligned}\Delta H^\circ_{\text{rxn}} &= \Sigma \Delta H^\circ_{\text{reactant bonds broken}} + \Sigma \Delta H^\circ_{\text{product bonds formed}} \\ &= 2648 \text{ kJ} + (-3052 \text{ kJ}) = -404 \text{ kJ}\end{aligned}$$

In addition to variations in experimental method, there is a more basic reason for the discrepancy between the $\Delta H^\circ_{\text{rxn}}$ obtained from bond energies (−404 kJ) and the value obtained by calorimetry (−802 kJ; Section 6.3) for the combustion of methane. A bond energy is an *average* value for a given bond in many compounds. The value *in a particular substance* is usually close, but not equal, to the average. For example, the C—H bond energy of 413 kJ/mol is the average for C—H bonds in many molecules. In fact, 415 kJ is actually required to break 1 mol of C—H bonds in methane, or 1660 kJ for 4 mol of these bonds. Thus, it isn't surprising to find discrepancies between $\Delta H^\circ_{\text{rxn}}$ values obtained in different ways.

SAMPLE PROBLEM 9.4 | Using Bond Energies to Calculate $\Delta H^\circ_{\text{rxn}}$

Problem Calculate $\Delta H^\circ_{\text{rxn}}$ for the chlorination of methane to form chloroform:

Plan All the reactant bonds break, and *all* the product bonds form. We find the bond energies in Table 9.2 and substitute the two sums, with correct signs, into Equation 9.2.

Solution Finding the standard enthalpy changes for bonds broken and for bonds formed: for bonds broken, the standard enthalpy change values are positive:

$$\begin{aligned}4 \times \text{C}-\text{H} &= (4 \text{ mol})(413 \text{ kJ/mol}) = 1652 \text{ kJ} \\ 3 \times \text{Cl}-\text{Cl} &= (3 \text{ mol})(243 \text{ kJ/mol}) = 729 \text{ kJ} \\ \Sigma \Delta H^\circ_{\text{bonds broken}} &= 2381 \text{ kJ}\end{aligned}$$

For bonds formed, the standard enthalpy change values are negative:

$$\begin{aligned}3 \times \text{C}-\text{Cl} &= (3 \text{ mol})(-350 \text{ kJ/mol}) = -1050 \text{ kJ} \\ 1 \times \text{C}-\text{H} &= (1 \text{ mol})(-413 \text{ kJ/mol}) = -413 \text{ kJ} \\ 3 \times \text{H}-\text{Cl} &= (3 \text{ mol})(-431 \text{ kJ/mol}) = -1293 \text{ kJ} \\ \Sigma \Delta H^\circ_{\text{bonds formed}} &= -2756 \text{ kJ}\end{aligned}$$

Calculating $\Delta H^\circ_{\text{rxn}}$:

$$\Delta H^\circ_{\text{rxn}} = \Sigma \Delta H^\circ_{\text{bonds broken}} + \Sigma \Delta H^\circ_{\text{bonds formed}} = 2381 \text{ kJ} + (-2756 \text{ kJ}) = -375 \text{ kJ}$$

Check The signs of the enthalpy changes are correct: $\Sigma \Delta H^\circ_{\text{bonds broken}} > 0$, and $\Sigma \Delta H^\circ_{\text{bonds formed}} < 0$. More energy is released than absorbed, so $\Delta H^\circ_{\text{rxn}}$ is negative:

$$\sim 2400 \text{ kJ} + [(-2800 \text{ kJ})] = -400 \text{ kJ}$$

SOME SIMILAR PROBLEMS 9.47–9.50

Bond Strengths and the Heat Released from Fuels, Foods, and Explosives

A fuel is a material that reacts with O_2 to release energy. The most common fuels are hydrocarbons (propane and octane, for example) and coal. These fuels contain organic molecules with many C—C and C—H bonds and fewer C—O and O—H bonds. During combustion, the bonds in the fuel molecules break and new bonds are formed in the products (CO_2 and H_2O). Because less energy is needed to break the weaker bonds in the fuel than is released when the stronger bonds in CO_2 and H_2O are formed, the combustion reaction is exothermic.

Fuels with more weak bonds yield more energy than fuels with fewer weak bonds. When a hydrocarbon (alkane) burns, C—C and C—H bonds break; when an alcohol burns, C—O and O—H bonds break as well. Table 9.2 shows that the sum for C—C and C—H bonds (783 kJ/mol) is less than the sum for C—O and O—H bonds (882 kJ/mol). Therefore, it takes more energy to break the bonds of a fuel with a lot of C—O and O—H bonds. Thus, in general, *a fuel with fewer bonds to O releases more energy* (Figure 9.19).

Fats and carbohydrates serve as fuels for organisms; these high-energy foods consist of chains or rings of C atoms attached to H atoms, with some C—O, C=O, and O—H bonds (shown in red below):

Fats have more of the weaker C—C and C—H bonds whereas carbohydrates have fewer chains of C atoms and bonds to H and more bonds to O, which are stronger. Therefore, fats provide more energy (“contain more Calories”) per gram than carbohydrates because fats have fewer bonds to O (Table 9.4).

Explosives are compounds that react very rapidly, releasing a large quantity of energy, and producing a large quantity of gaseous products. Several common explosives, such as nitroglycerin and trinitrotoluene (TNT), contain N atoms. During the reaction, extremely strong bonds form in the products N_2 ($N\equiv N$; BE = 945 kJ/mol) and CO ($C\equiv O$; BE = 1077 kJ/mol). Since weaker bonds break and significantly stronger bonds form, these reactions are highly exothermic; the decomposition reaction of TNT is shown below:

Summary of Section 9.4

- › The only component of internal energy that changes significantly during a reaction is the bond energies of reactants and products, and this change appears as the enthalpy of reaction, $\Delta H^\circ_{\text{rxn}}$.
- › A reaction involves breaking reactant bonds and forming product bonds. Applying Hess's law, we use tabulated bond energies to calculate $\Delta H^\circ_{\text{rxn}}$.
- › Bonds in fuels are weaker than bonds in the combustion products. Fuels with more weak bonds release more energy than fuels with fewer. Bonds in explosives are weaker than the bonds of the decomposition products, so a large quantity of energy is released.

Figure 9.19 Relative bond strength and energy from fuels.

BETWEEN THE EXTREMES:
ELECTRONEGATIVITY AND BOND POLARITY

Scientific models are idealized descriptions of reality. The ionic and covalent bonding models portray compounds as formed by *either* complete electron transfer *or* complete electron sharing. But, in real substances, most atoms are joined by bonds that are between pure ionic and pure covalent. In this section, we explore the “in-between” nature of these bonds and its importance for the properties of substances.

Electronegativity

To explain why some bonds are between pure ionic and pure covalent, we need to examine the following property of elements:

- **Electronegativity (EN)** is the relative ability of a bonded atom to attract shared electrons.*

The more electronegative an atom is, the greater its attraction for the shared electrons in the bond. From studies with many compounds, the chemist Linus Pauling derived a scale of *relative EN values* based on fluorine having the highest EN value, 4.0 (Figure 9.20).

Trends in Electronegativity In general, *electronegativity is inversely related to atomic size* because the nucleus of a smaller atom is closer to the shared pair than the nucleus of a larger atom, so it attracts the electrons more strongly (Figure 9.21):

- *Down a main group*, electronegativity (height of post) decreases as atomic size (hemisphere on top of post) increases.
- *Across a period of main-group elements*, electronegativity increases.
- Nonmetals are *more* electronegative than metals.

*Electronegativity refers to a bonded atom attracting a shared pair; *electron affinity* refers to a gaseous atom gaining an electron to form an anion. Elements with a high EN also have a highly negative EA.

Figure 9.20 The Pauling electronegativity (EN) scale. The height of each post is proportional to the EN, which is shown on top. The key has several EN cutoffs. In the main groups, EN *increases* across and *decreases* down. The transition and inner transition elements show little change in EN. Here hydrogen is placed near elements with similar EN values.

Figure 9.21 Electronegativity and atomic size.

The most electronegative element is fluorine, with oxygen a close second. Thus, except when it bonds with fluorine, oxygen always pulls bonding electrons toward itself. The least electronegative element (also referred to as the most *electropositive*) is francium (Fr), in the lower left corner of the periodic table, but it is radioactive and extremely rare, so, for all practical purposes, cesium (Cs) is the most electropositive.

Bond Polarity and Partial Ionic Character

Whenever atoms having different electronegativities form a bond, such as H (EN = 2.1) and F (EN = 4.0) in HF, the bonding pair is shared *unequally* as the more electronegative atom attracts the shared pair more strongly than the less electronegative atom. This unequal distribution of electron density results in a **polar covalent bond**. The unequal distribution is indicated by a polar arrow, $\rightarrow$, pointing toward the partially negative pole (the more electronegative atom) or by the symbols $\delta+$ and $\delta-$ (see Figure 4.4):

In the H—H and F—F bonds, where the atoms are identical, the bonding pair is shared *equally*, and a **nonpolar covalent bond** results. In Figure 9.22, electron density models and relief maps show the distribution of electron density in H₂, F₂, and HF.

Figure 9.22 Electron density distributions for H₂, F₂, and HF. In HF, the electron density shifts from H to F. In the electron density models, regions of high negative charge are shown in red and regions of high positive charge are shown in blue. (The electron density peak for F has been cut off in the relief maps to limit the figure height.)

Figure 9.23 ΔEN ranges for classifying the partial ionic character of bonds.

The Importance of Electronegativity Difference (ΔEN) The **electronegativity difference (ΔEN)**, the difference between the EN values of the bonded atoms, is directly related to a bond's polarity. It ranges from 0.0 in a diatomic element, such as H_2 , O_2 , or Cl_2 , all the way up to 3.3, the difference between the most electronegative atom, F (4.0), and the most electropositive, Cs (0.7), in the ionic compound CsF.

Another parameter closely related to ΔEN is the **partial ionic character** of a bond: *a greater ΔEN results in larger partial charges and higher partial ionic character*. Consider three Cl-containing gaseous molecules:

$LiCl(g):$	$\Delta EN = 3.0 - 1.0 = 2.0$	↓ ionic character decreases
$HCl(g):$	$\Delta EN = 3.0 - 2.1 = 0.9$	
$Cl_2(g):$	$\Delta EN = 3.0 - 3.0 = 0.0$	

The bond in $LiCl$ has more ionic character than the one in HCl , which has more than the one in Cl_2 .

Here are two approaches for quantifying ionic character. Both use arbitrary cut-offs, which is not really consistent with the actual gradation in bonding:

1. **ΔEN range.** This approach divides bonds into mostly ionic, polar covalent, mostly covalent, and nonpolar covalent based on a range of ΔEN values (Figure 9.23).
2. **Percent ionic character.** This approach is based on the behavior of a gaseous diatomic molecule in an electric field. A plot of *percent ionic character* vs. ΔEN for several molecules shows that, as expected, *percent ionic character generally increases with ΔEN* (Figure 9.24A). A value of 50% divides ionic from covalent bonds. Note that a substance like $Cl_2(g)$ has 0% ionic character, but none has 100% ionic character: *electron sharing occurs to some extent in every bond, even between an ion pair of an alkali halide* (Figure 9.24B).

Figure 9.24 Percent ionic character as a function of ΔEN . **A**, ΔEN correlates with ionic character. **B**, Even in highly ionic LiF ($\Delta EN = 3.0$), some electron sharing occurs between the ions in the gaseous ion pair.

Student Hot Spot

Student data indicate that you may struggle with using electronegativity to determine bond polarity. Access the eBook to view an additional Learning Resource video on this topic.

SAMPLE PROBLEM 9.5 | Determining Bond Polarity from EN Values

Problem (a) Use a polar arrow to indicate the polarity of each bond: N—H, F—N, I—Cl.

(b) Rank the following bonds in order of *increasing* polarity and *decreasing* percent ionic character: H—N, H—O, H—C.

Plan (a) We use Figure 9.20 to find the EN values for the atoms and point the polar arrow toward the more electronegative atom, which is the negative end of the bond.

(b) To rank the bond polarity, we determine ΔEN : the higher the value, the greater the polarity. Percent ionic character is also directly related to ΔEN (and bond polarity); it decreases in the opposite order that polarity increases.

Solution (a) The EN of N = 3.0 and the EN of H = 2.1, so $\text{N} \leftarrow \text{H}$.

The EN of F = 4.0 and the EN of N = 3.0, so $\text{F} \leftarrow \text{N}$.

The EN of I = 2.5 and the EN of Cl = 3.0, so $\text{I} \rightarrow \text{Cl}$.

(b) The ΔEN values are $3.0 - 2.1 = 0.9$ for H—N, $3.5 - 2.1 = 1.4$ for H—O, and $2.5 - 2.1 = 0.4$ for H—C.

The order of *increasing* bond polarity is $\text{H—C} < \text{H—N} < \text{H—O}$.

The order of *decreasing* percent ionic character is $\text{H—O} > \text{H—N} > \text{H—C}$.

Check In (b), we can check the order of bond polarity using periodic trends. Each bond involves H and a Period 2 atom. Since atomic size decreases and EN increases across a period, the polarity is greatest for the bond to O (farthest to the right in Period 2).

Comment In Chapter 10, you'll see that the bond polarity contributes to the overall polarity of the molecule, which is a major factor in determining behavior.

FOLLOW-UP PROBLEMS

9.5A Arrange each set of bonds in order of *increasing* polarity, and indicate bond polarity with $\delta+$ and $\delta-$ symbols:

(a) Cl—F, Br—Cl, Cl—Cl (b) P—F, N—O, N—F

9.5B Arrange each set of bonds in order of *decreasing* polarity, and indicate bond polarity with a polar arrow:

(a) Se—Cl, Se—F, Se—Br (b) S—B, F—B, Cl—B

SOME SIMILAR PROBLEMS 9.60–9.63, 9.66, and 9.67

The Gradation in Bonding Across a Period

A metal and a nonmetal—elements from the left and right sides of the periodic table—have a relatively large ΔEN and typically form an ionic compound. Two nonmetals—both from the right side of the table—have a small ΔEN and form a covalent compound. When we combine chlorine with each of the Period 3 elements, starting with sodium, we observe a steady decrease in ΔEN and a gradation in bond type from ionic through polar covalent to nonpolar covalent.

Figure 9.25 shows an electron density relief map of a bond in each of the common Period 3 chlorides; note the steady increase in the height of electron density *between* the peaks—the bonding region—which indicates an *increase in electron sharing*. Figure 9.26 shows samples of common Period 3 chlorides—NaCl, MgCl_2 , AlCl_3 , SiCl_4 , PCl_3 , and SCl_2 , as well as Cl_2 —along with the change in ΔEN and two physical properties, melting point and electrical conductivity:

- **NaCl.** Sodium chloride is a white (colorless) crystalline solid with a ΔEN of 2.1, a high melting point, and high electrical conductivity when molten—ionic by any criterion. Nevertheless, just as for LiF (see Figure 9.24B), a small but significant amount of electron sharing appears in the electron density relief map for NaCl.
- **MgCl_2 .** With a ΔEN of 1.8, magnesium chloride is still ionic, but it has a lower melting point and lower conductivity, as well as slightly more electron sharing, than NaCl.
- **AlCl_3 .** Rather than being a three-dimensional lattice of Al^{3+} and Cl^- ions, aluminum chloride, with a ΔEN value of 1.5, consists of layers of highly polar Al—Cl bonds. Weak forces between layers result in a much lower melting point,

Figure 9.25 Electron density relief maps for bonds of Period 3 chlorides. The ΔEN value for each bond is under its relief map. Note the steady increase in electron sharing from NaCl to Cl_2 .

Figure 9.26 Properties of Period 3 chlorides. As ΔEN decreases, melting point (mp) and electrical conductivity decrease because the bond type changes from ionic to polar covalent to nonpolar covalent.

Source: Stephen Frisch/McGraw Hill

and the low conductivity implies few free ions. Electron density between the nuclei is even higher than in $MgCl_2$. $AlCl_3$ has less ionic character than $NaCl$ or $MgCl_2$.

- $SiCl_4$, PCl_3 , SCl_2 , and Cl_2 . The trend toward bonding that is more covalent continues through the remaining substances. The three compounds, with polar covalent bonds, occur as separate molecules, which have no conductivity (no ions) and such weak forces *between* them that melting points are below $0^\circ C$. In Cl_2 , the bond is nonpolar ($\Delta EN = 0.0$). The relief maps show the increasing electron density in the bonding region.

Thus, as ΔEN decreases, the bond becomes more covalent, and the character of the substance changes from ionic solid to covalent gas.

Summary of Section 9.5

- › Electronegativity is the ability of a bonded atom to attract shared electrons, which generates opposite partial charges at the ends of the bond and contributes to the bond energy.
- › Electronegativity increases across a period and decreases down a group, the reverse of the trends in atomic size.
- › The larger the ΔEN for two bonded atoms, the more polar the bond is and the greater its ionic character.
- › For Period 3 chlorides, there is a gradation in bond type from ionic to polar covalent to nonpolar covalent.

9.6 AN INTRODUCTION TO METALLIC BONDING

In this section, you'll see how a simple, qualitative model for metallic bonding accounts for the properties of metals; a more detailed model is presented in Chapter 12.

The Electron-Sea Model

Metals can transfer electrons to nonmetals and form ionic solids, such as NaCl. And experiments with metals in the gas phase show that two metal atoms can even share their valence electrons to form gaseous, diatomic molecules, such as Na₂. But what holds the atoms together in a chunk of Na metal? The **electron-sea model** of metallic bonding proposes that all the metal atoms in the sample contribute their valence electrons to form a delocalized electron “sea” throughout the piece, with the metal ions (nuclei and core electrons) lying in an orderly array (see Figure 9.2C). *All the atoms in the sample share the electrons*, and the piece is held together by the mutual attraction of the metal cations for the mobile valence electrons. Thus, bonding in metals is fundamentally different than the other two types:

- *In contrast to ionic bonding*, no anions are present, and the metal ions are not held in place as rigidly.
- *In contrast to covalent bonding*, no particular pair of metal atoms is bonded through a localized electron pair.
- *Instead of forming compounds*, two or more metals typically form **alloys**, solid mixtures of variable composition. Alloys appear in car and airplane bodies, bridges, coins, jewelry, dental fillings, and many other familiar objects; brass, bronze, and stainless steel are common alloys.

How the Model Explains the Properties of Metals

The physical properties of metals vary over a wide range. Two features of the electron-sea model that account for these properties are (1) the *regularity*, without rigidity, of the metal-ion array and (2) the *number* and *mobility* of the valence electrons.

1. **Melting and boiling points.** Nearly all metals are solids with moderate to high melting points and much higher boiling points (Table 9.5). These properties are related to the energy of the metallic bonding. Melting points are only moderately high because the cations can move without disrupting their attraction to the surrounding electrons. Boiling points are very high because each cation and its valence electron(s) must break away from the others to vaporize. Gallium provides a striking example: it can melt in your hand (mp 29.8°C) but doesn't boil until over 2400°C.

Periodic trends are consistent with the strength of the bonding:

- *Down a group*, melting points decrease because the larger metal ions have a weaker attraction to the electron sea.
- *Across a period*, melting points increase. Alkaline earth metals (Group 2) have higher melting points than alkali metals (Group 1) because their 2+ cations have stronger attractions to twice as many valence electrons (Figure 9.27).

Table 9.5 Melting and Boiling Points of Some Metals

Element	mp (°C)	bp (°C)
Lithium (Li)	180	1347
Tin (Sn)	232	2623
Aluminum (Al)	660	2467
Barium (Ba)	727	1850
Silver (Ag)	961	2155
Copper (Cu)	1083	2570
Uranium (U)	1130	3930

Figure 9.27 Melting points of Group 1 and Group 2 metals.**Figure 9.28** Why metals dent and bend rather than crack.

Source: Stephen Frisch/McGraw Hill

2. *Mechanical properties.* When a piece of metal is deformed by a hammer, the metal ions do not repel each other, but rather slide past each other through the electron sea and end up in new positions; thus, metals dent and bend, as shown in Figure 9.28. Compare this behavior with the interionic repulsions that occur when an ionic solid is struck (see Figure 9.10).

The common Group 11 metals—copper, silver, and gold—are all soft enough to be machined into sheets (malleable) and wires (ductile), but gold is in a class by itself. One gram of gold, about the size of a small ball-bearing, can be drawn into a wire 20 μm thick and 165 m long or hammered into a 1.0- m^2 sheet that is 230 atoms (about 70 nm) thick (see photo)!

**How thin is gold leaf?**Source: Creativ Studio Heinemann/
Westend61 GmbH/Alamy Stock Photo

3. *Electrical conductivity.* Unlike ionic and covalent substances, metals are good conductors of electricity in both the solid and liquid states because of their mobile electrons. When a piece of metal wire is attached to a battery, electrons flow from the negative terminal into the wire, replacing the electrons that flow from the wire into the positive terminal. Foreign atoms disrupt the array of metal atoms and reduce conductivity. Copper used in electrical wiring is over 99.99% pure because traces of other atoms drastically restrict electron flow.

4. *Thermal conductivity.* Mobile electrons also make metals good conductors of heat. Place your hand on a piece of metal and a piece of wood that are both at room temperature. The metal feels colder because it conducts heat away from your hand much faster than the wood. The mobile, delocalized electrons in the metal disperse the heat from your hand more quickly than the localized electron pairs in the covalent bonds of wood.

› Summary of Section 9.6

- › According to the electron-sea model, the valence electrons of the metal atoms in a sample are highly delocalized and attract all the metal cations, holding them together.
- › Metals have only moderately high melting points because the metal ions remain attracted to the electrons in the electron sea, even if their relative positions change.

- › Vaporization involves complete separation of individual cations with their valence electrons from all the others, so metals have very high boiling points.
- › Metals can be deformed because the electron sea prevents repulsions among the cations.
- › Metals conduct electricity and heat because their electrons are mobile.

CHAPTER REVIEW GUIDE

Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

Understand These Concepts

1. How differences in atomic properties lead to differences in bond type; the basic distinctions among the three types of bonding (§9.1)
2. The essential features of ionic bonding: electron transfer to form ions, and their electrostatic attraction to form a solid (§9.2)
3. How lattice energy is ultimately responsible for the formation of ionic compounds (§9.2)
4. How ionic compound formation is conceptualized as occurring in steps (a Born-Haber cycle) to calculate the lattice energy (§9.2)
5. How Coulomb's law explains the periodic trends in lattice energy (§9.2)
6. Why ionic compounds are brittle and high melting and conduct electricity only when molten or dissolved in water (§9.2)
7. How nonmetal atoms form a covalent bond (§9.3)
8. How bonding and lone electron pairs fill the outer (valence) level of each atom in a molecule (§9.3)
9. The interrelationships among bond order, bond length, and bond energy (§9.3)
10. How the distinction between bonding and nonbonding forces explains the properties of covalent molecules and network covalent solids (§9.3)
11. How changes in bond energy account for the enthalpy of reaction (§9.4)
12. How a reaction can be divided conceptually into bond-breaking and bond-forming steps (§9.4)

13. The periodic trends in electronegativity and the inverse relationship of EN values to atomic sizes (§9.5)
14. How bond polarity arises from differences in the electronegativities of the bonded atoms; the direction of bond polarity (§9.5)
15. The relation of partial ionic character to ΔEN and the change from ionic to polar covalent to nonpolar covalent bonding across a period (§9.5)
16. The role of delocalized electrons in metallic bonding (§9.6)
17. How the electron-sea model explains why metals bend, have very high boiling points, and conduct electricity in solid or molten form (§9.6)

Master These Skills

1. Using Lewis electron-dot symbols to depict main-group atoms (§9.1)
2. Depicting the formation of ions with partial orbital diagrams and Lewis symbols, and writing the formula of the ionic compound (SP 9.1)
3. Calculating lattice energy from the enthalpies of the steps to ionic compound formation (§9.2)
4. Ranking lattice energies from ionic properties (SP 9.2)
5. Ranking similar covalent bonds according to their length and strength (SP 9.3)
6. Using bond energies to calculate $\Delta H^\circ_{\text{rxn}}$ (SP 9.4)
7. Determining bond polarity from EN values (SP 9.5)

Key Terms

Page numbers appear in parentheses.

alloy (389)	covalent bond (374)	infrared (IR) spectroscopy (378)	metallic bonding (365)
bond energy (BE) (375)	covalent bonding (364)	ion pairs (373)	nonpolar covalent bond (385)
bond length (376)	double bond (374)	ionic bonding (364)	octet rule (366)
bond order (374)	electronegativity (EN) (384)	lattice energy ($\Delta H^\circ_{\text{lattice}}$) (368)	partial ionic character (386)
bonding (shared) pair (374)	electronegativity difference (ΔEN) (386)	Lewis electron-dot symbol (365)	polar covalent bond (385)
Born-Haber cycle (368)	electron-sea model (389)	lone (unshared) pair (374)	single bond (374)
Coulomb's law (370)			triple bond (375)

Key Equations and Relationships

Page numbers appear in parentheses.

9.1 Relating the energy of attraction to the lattice energy (370):

$$\text{Electrostatic energy} \propto \frac{\text{cation charge} \times \text{anion charge}}{\text{cation radius} + \text{anion radius}} \propto \Delta H^\circ_{\text{lattice}}$$

9.2 Calculating enthalpy of reaction from bond enthalpies or bond energies (380):

$$\Delta H^\circ_{\text{rxn}} = \Sigma \Delta H^\circ_{\text{reactant bonds broken}} + \Sigma \Delta H^\circ_{\text{product bonds formed}}$$

or

$$\Delta H^\circ_{\text{rxn}} = \Sigma \text{BE}_{\text{reactant bonds broken}} - \Sigma \text{BE}_{\text{product bonds formed}}$$

CHAPTER PRACTICE TEST

The answers to the Practice Test problems are shown below and the full solutions can be found in the e-book.

1. ΔEN for elements A and B is 2.1. This indicates that

- (a) A and B are both metallic elements.
- (b) compound AB has a low melting point.
- (c) the bond in compound AB is a coordinate covalent bond.
- (d) the bond in compound AB is principally covalent in character.
- (e) the bond in compound AB is principally ionic in character.

2. Which of the following bonds is the most polar?

- (a) C—F
- (b) C—Cl
- (c) N—F
- (d) N—Cl
- (e) O—F
- (f) O—Cl

3. In which of the following pairs of ionic compounds is the compound with the higher lattice energy listed first?

- (a) NaBr vs. MgS
- (b) BaCl₂ vs. SrCl₂
- (c) AlBr₃ vs. AlCl₃
- (d) Cs₂S vs. KBr
- (e) RbCl vs. KCl

4. Which of the following **two** substances most likely have polar covalent bonds? Select **both** correct answers.

- (a) SrCl₂
- (b) CO₂
- (c) S₈
- (d) TiF₂
- (e) ClF
- (f) CsCl

5. Which of the following statements about an endothermic reaction is always true?

- (a) Weak bonds break and strong bonds form.
- (b) More energy is required to break bonds than is released in bond formation.
- (c) Energy is released as the reaction takes place.
- (d) Less energy is required to break bonds than is released in bond formation.
- (e) Double bonds are always broken in an endothermic reaction.
- (f) Fewer bonds form in the products than are broken in the reactants.

6. A N≡N bond has a _____ bond order, _____ bond length, and _____ bond energy than a N=O bond.

- (a) higher, longer, smaller
- (b) higher, shorter, greater
- (c) higher, longer, greater
- (d) lower, longer, smaller
- (e) lower, shorter, greater
- (f) lower, longer, greater

7. Use bond energies from Table 9.2 to calculate the enthalpy of reaction ($\Delta H_{\text{rxn}}^\circ$) for the following reaction:

- (a) -1634 kJ
- (b) 1494 kJ
- (c) -1668 kJ
- (d) 1012 kJ
- (e) -826 kJ
- (f) -268 kJ

8. Which of the following lists the bonds from longest to shortest bond (decreasing bond length)?

- (a) C=O > C—S > C—O > C—F
- (b) C=O > C—F > C—O > C—S
- (c) C—O > C—F > C=O > C—S
- (d) C—O > C—S > C—F > C=O
- (e) C—S > C—O > C—F > C=O
- (f) C—S > C—F > C=O > C—O

9. Analysis of an unknown substance showed that it has a high boiling point and is brittle. It conducts electricity when melted, but not in the solid form. Which of the following substances would have those characteristics?

- (a) HCl
- (b) Al
- (c) KBr
- (d) SiF₄
- (e) I₂

10. Which of the following has bonds with the greatest percentage ionic character?

- (a) HF
- (b) H₂O
- (c) CH₄
- (d) O₂
- (e) NH₃

Answers: 1. e; 2. a; 3. d; 4. b, e; 5. b; 6. b; 7. c; 8. e; 9. c; 10. a

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

9.2A BaF_2 . The only difference between these compounds is the size of the cation: the Ba^{2+} ion is larger than the Sr^{2+} ion (ionic size increases down the group), so the lattice energy of BaF_2 is smaller than that of SrF_2 .

9.2B $\text{Na}_2\text{O} < \text{MgF}_2 < \text{CaO}$. In Na_2O , the ions are Na^+ and O^{2-} ; the ions in MgF_2 are Mg^{2+} and F^- . The products of the cation charge and anion charge (Equation 9.1) are the same for these two compounds (1×2 and 2×1); however, since Na^+ is larger than Mg^{2+} , and O^{2-} is larger than F^- , Na_2O has the smaller lattice energy. In CaO , the ions are Ca^{2+} and O^{2-} . The larger product of cation and anion charge (2×2 for CaO) results in a larger lattice energy for CaO . In nearly every case, charge is more important than size.

9.3A (a) All three bonds have a bond order of 3. Since atomic size decreases left to right across a period, $\text{C} > \text{N} > \text{O}$.

Bond length: $\text{C}\equiv\text{N} > \text{N}\equiv\text{N} > \text{N}\equiv\text{O}$

Bond strength: $\text{N}\equiv\text{O} > \text{N}\equiv\text{N} > \text{C}\equiv\text{N}$

(b) All three bonds have a bond order of 1. Since atomic size increases down a group, $\text{I} > \text{Br} > \text{F}$.

Bond length: $\text{P—I} > \text{P—Br} > \text{P—F}$

Bond strength: $\text{P—F} > \text{P—Br} > \text{P—I}$

9.3B (a) All three bonds have a bond order of 1. Since atomic size decreases left to right across a period and increases down a group, $\text{F} < \text{O} < \text{S}$.

Bond length: $\text{Si—F} < \text{Si—O} < \text{Si—S}$

Bond strength: $\text{Si—S} < \text{Si—O} < \text{Si—F}$

(b) As bond order decreases, bond length increases and bond strength decreases.

Bond length: $\text{N}\equiv\text{N} < \text{N}=\text{N} < \text{N—N}$

Bond strength: $\text{N—N} < \text{N}=\text{N} < \text{N}\equiv\text{N}$

9.4A

$$\begin{aligned}\Sigma\Delta H_{\text{bonds broken}}^{\circ} &= 1 \text{ N}\equiv\text{N} + 3 \text{ H—H} \\ &= (1 \text{ mol})(945 \text{ kJ/mol}) + (3 \text{ mol})(436 \text{ kJ/mol}) \\ &= 2253 \text{ kJ}\end{aligned}$$

$$\Sigma\Delta H_{\text{bonds formed}}^{\circ} = 6 \text{ N—H} = (6 \text{ mol})(-391 \text{ kJ/mol}) = -2346 \text{ kJ}$$

$$\begin{aligned}\Delta H_{\text{rxn}}^{\circ} &= \Sigma\Delta H_{\text{bonds broken}}^{\circ} + \Sigma\Delta H_{\text{bonds formed}}^{\circ} \\ &= 2253 \text{ kJ} + (-2346 \text{ kJ}) = -93 \text{ kJ}\end{aligned}$$

9.4B

$$\begin{aligned}\Sigma\Delta H_{\text{bonds broken}}^{\circ} &= 2 \text{ O—F} + 2 \text{ O—H} \\ &= (2 \text{ mol})(215 \text{ kJ/mol}) + (2 \text{ mol})(497 \text{ kJ/mol}) \\ &= 1424 \text{ kJ}\end{aligned}$$

$$\begin{aligned}\Sigma\Delta H_{\text{bonds formed}}^{\circ} &= 2 \text{ H—F} + 1 \text{ O}=\text{O} \\ &= (2 \text{ mol})(-570 \text{ kJ/mol}) + (1 \text{ mol})(-498 \text{ kJ/mol}) \\ &= -1638 \text{ kJ}\end{aligned}$$

$$\begin{aligned}\Delta H_{\text{rxn}}^{\circ} &= \Sigma\Delta H_{\text{bonds broken}}^{\circ} + \Sigma\Delta H_{\text{bonds formed}}^{\circ} \\ &= 1424 \text{ kJ} + (-1638 \text{ kJ}) = -214 \text{ kJ}\end{aligned}$$

9.5A (a) Cl—F : $\Delta\text{EN} = 4.0 - 3.0 = 1.0$;

Br—Cl : $\Delta\text{EN} = 3.0 - 2.8 = 0.2$; Cl—Cl : $\Delta\text{EN} = 3.0 - 3.0 = 0$

$\text{Cl—Cl} < \overset{\delta+}{\text{Br}}-\overset{\delta-}{\text{Cl}} < \overset{\delta+}{\text{Cl}}-\overset{\delta-}{\text{F}}$

(b) P—F : $\Delta\text{EN} = 4.0 - 2.1 = 1.9$; N—O : $\Delta\text{EN} = 3.5 - 3.0 = 0.5$;

N—F : $\Delta\text{EN} = 4.0 - 3.0 = 1.0$

$\overset{\delta+}{\text{N}}-\overset{\delta-}{\text{O}} < \overset{\delta+}{\text{N}}-\overset{\delta-}{\text{F}} < \overset{\delta+}{\text{P}}-\overset{\delta-}{\text{F}}$

9.5B (a) Se—Cl : $\Delta\text{EN} = 3.0 - 2.4 = 0.6$;

Se—F : $\Delta\text{EN} = 4.0 - 2.4 = 1.6$; Se—Br : $\Delta\text{EN} = 2.8 - 2.4 = 0.4$

$\text{Se—F} > \text{Se—Cl} > \text{Se—Br}$

(b) S—B : $\Delta\text{EN} = 2.5 - 2.0 = 0.5$; F—B : $\Delta\text{EN} = 4.0 - 2.0 = 2.0$;

Cl—B : $\Delta\text{EN} = 3.0 - 2.0 = 1.0$

$\text{F—B} > \text{Cl—B} > \text{S—B}$

PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

Atomic Properties and Chemical Bonds

Concept Review Questions

9.1 In general terms, how does each of the following atomic properties influence the metallic character of the main-group elements in a period?

- | | |
|-------------------------------|------------------------------|
| (a) Ionization energy | (b) Atomic radius |
| (c) Number of outer electrons | (d) Effective nuclear charge |

9.2 Three solids are represented below. What is the predominant type of bonding in each?

9.3 What is the relationship between the tendency of a main-group element to form a monatomic ion and its position in the periodic table? In what part of the table are the main-group elements that typically form cations? Anions?

Skill-Building Exercises (grouped in similar pairs)

9.4 Which member of each pair is *more* metallic?

- (a) Na or Cs (b) Mg or Rb (c) As or N

9.5 Which member of each pair is *less* metallic?

- (a) I or O (b) Be or Ba (c) Se or Ge

9.6 State the type of bonding—ionic, covalent, or metallic—you would expect in each:

- (a) CsF(s) (b) N₂(g) (c) Na(s)

9.7 State the type of bonding—ionic, covalent, or metallic—you would expect in each:

- (a) ICl₃(s) (b) N₂O(g) (c) LiCl(s)

9.8 State the type of bonding—ionic, covalent, or metallic—you would expect in each:

- (a) O₃(g) (b) MgCl₂(s) (c) BrO₂(g)

9.9 State the type of bonding—ionic, covalent, or metallic—you would expect in each:

- (a) Cr(s) (b) H₂S(g) (c) CaO(s)

9.10 Draw a Lewis electron-dot symbol for each atom:

- (a) Rb (b) Si (c) I

9.11 Draw a Lewis electron-dot symbol for each atom:

- (a) Ba (b) Kr (c) Br

9.12 Draw a Lewis electron-dot symbol for each:

- (a) Sr (b) P (c) S

9.13 Draw a Lewis electron-dot symbol for each:

- (a) As (b) Se (c) Ga

9.14 Give the group number and condensed electron configuration of an element corresponding to each electron-dot symbol:

- (a) $\cdot\ddot{X}:$ (b) $\ddot{X}\cdot$

9.15 Give the group number and condensed electron configuration of an element corresponding to each electron-dot symbol:

- (a) $\cdot\ddot{X}:$ (b) $\ddot{X}\cdot$

The Ionic Bonding Model

(Sample Problems 9.1 and 9.2)

Concept Review Questions

9.16 If energy is required to form monatomic ions from metals and nonmetals, why do ionic compounds exist?

9.17 (a) In general, how does the lattice energy of an ionic compound depend on the charges and sizes of the ions?

(b) Ion arrangements of three general salts are represented below. Rank them in order of increasing lattice energy.

9.18 When gaseous Na⁺ and Cl[−] ions form ion pairs, 548 kJ/mol of energy is released. Why, then, does NaCl occur as a solid under ordinary conditions?

9.19 To form S^{2−} ions from gaseous sulfur atoms requires 214 kJ/mol, but these ions exist in solids such as K₂S. Explain.

Skill-Building Exercises (grouped in similar pairs)

9.20 Use condensed electron configurations and Lewis electron-dot symbols to depict the ions formed from each of the following atoms, and predict the formula of their compound:

- (a) Ba and Cl (b) Sr and O (c) Al and F (d) Rb and O

9.21 Use condensed electron configurations and Lewis electron-dot symbols to depict the ions formed from each of the following atoms, and predict the formula of their compound:

- (a) Cs and S (b) O and Ga (c) N and Mg (d) Br and Li

9.22 For each ionic compound formula, identify the main group to which X belongs:

- (a) XF₂ (b) MgX (c) X₂SO₄

9.23 For each ionic compound formula, identify the main group to which X belongs:

- (a) X₃PO₄ (b) X₂(SO₄)₃ (c) X(NO₃)₂

9.24 For each ionic compound formula, identify the main group to which X belongs:

- (a) X₂O₃ (b) XCO₃ (c) Na₂X

9.25 For each ionic compound formula, identify the main group to which X belongs:

- (a) CaX₂ (b) Al₂X₃ (c) XPO₄

9.26 For each pair, choose the compound with the larger lattice energy, and explain your choice:

- (a) BaS or CsCl (b) LiCl or CsCl

9.27 For each pair, choose the compound with the larger lattice energy, and explain your choice:

- (a) CaO or CaS (b) BaO or SrO

9.28 For each pair, choose the compound with the smaller lattice energy, and explain your choice:

- (a) CaS or BaS (b) NaF or MgO

9.29 For each pair, choose the compound with the smaller lattice energy, and explain your choice:

- (a) NaF or NaCl (b) K₂O or K₂S

9.30 Use the following to calculate $\Delta H^\circ_{\text{lattice}}$ of NaCl:

Compared with the lattice energy of LiF (1050 kJ/mol), is the magnitude of the value for NaCl what you expected? Explain.

9.31 Use the following to calculate $\Delta H^\circ_{\text{lattice}}$ of MgF_2 :

Compared with the lattice energy of LiF (1050 kJ/mol) or the lattice energy you calculated for NaCl in Problem 9.30, does the relative magnitude of the value for MgF_2 surprise you? Explain.

Problems in Context

9.32 Aluminum oxide (Al_2O_3) is a widely used industrial abrasive (known as emery or corundum), for which the specific application depends on the hardness of the crystal. What does this hardness imply about the magnitude of the lattice energy? Would you have predicted from the chemical formula that Al_2O_3 is hard? Explain.

9.33 Born-Haber cycles were used to obtain the first reliable values for electron affinity by considering the EA value as the unknown and using a theoretically calculated value for the lattice energy. Use a Born-Haber cycle for KF and the following values to calculate a value for the electron affinity of fluorine:

The Covalent Bonding Model

(Sample Problem 9.3)

Concept Review Questions

9.34 Describe the interactions that occur between individual chlorine atoms as they approach each other and form Cl_2 . What combination of forces gives rise to the energy holding the atoms together and to the final internuclear distance?

9.35 Define *bond energy* using the H—Cl bond as an example. When this bond breaks, is energy absorbed or released? Is the accompanying ΔH value positive or negative? How do the magnitude and sign of this ΔH value relate to the value that accompanies H—Cl bond formation?

9.36 For single bonds between similar types of atoms, how does the strength of the bond relate to the sizes of the atoms? Explain.

9.37 How does the energy of the bond between a given pair of atoms relate to the bond order? Why?

9.38 When liquid benzene (C_6H_6) boils, does the gas consist of molecules, ions, or separate atoms? Explain.

Skill-Building Exercises (grouped in similar pairs)

9.39 Using the periodic table only, arrange the members of each of the following sets in order of increasing bond *strength*:

- (a) Br—Br , Cl—Cl , I—I (b) S—H , S—Br , S—Cl
(c) C=N , C—N , $\text{C}\equiv\text{N}$

9.40 Using the periodic table only, arrange the members of each of the following sets in order of increasing bond *length*:

- (a) H—F , H—I , H—Cl (b) C—S , C=O , C—O
(c) N—H , N—S , N—O

Problem in Context

9.41 Formic acid (HCOOH ; structural formula shown below) is secreted by certain species of ants when they bite.

Rank the relative strengths of

- (a) the C—O and C=O bonds and
(b) the H—C and O—H bonds. Explain these rankings.

Bond Energy and Chemical Change

(Sample Problem 9.4)

Concept Review Questions

9.42 Write a solution plan (without actual numbers but including the bond energies you would use and how you would combine them algebraically) for calculating the total enthalpy change of the following reaction:

9.43 The text points out that, for similar types of substances, one with weaker bonds is usually more reactive than one with stronger bonds. Why is this generally true?

9.44 Why is there a discrepancy between an enthalpy of reaction obtained from calorimetry and one obtained from bond energies?

Skill-Building Exercises (grouped in similar pairs)

9.45 Which of the following gases would you expect to have the greater enthalpy of reaction per mole for combustion? Why?

methane or formaldehyde

9.46 Which of the following gases would you expect to have the greater enthalpy of reaction per mole for combustion? Why?

ethanol or methanol

9.47 Use bond energies to calculate the enthalpy of reaction:

9.48 Use bond energies to calculate the enthalpy of reaction:

Problems in Context

9.49 An important industrial route to extremely pure acetic acid is the reaction of methanol with carbon monoxide:

Use bond energies to calculate the enthalpy of reaction.

9.50 Sports trainers treat sprains and soreness with ethyl bromide. It is manufactured by reacting ethylene with hydrogen bromide:

Use bond energies to find the enthalpy of reaction.

Between the Extremes: Electronegativity and Bond Polarity (Sample Problem 9.5)

Concept Review Questions

9.51 Describe the vertical and horizontal trends in electronegativity (EN) among the main-group elements. According to Pauling's scale, what are the two most electronegative elements? The two least electronegative elements?

9.52 What is the general relationship between IE_1 and EN for the elements? Why?

9.53 Is the H—O bond in water nonpolar covalent, polar covalent, or ionic? Define each term, and explain your choice.

9.54 How does electronegativity differ from electron affinity?

9.55 How is the partial ionic character of a bond in a diatomic molecule related to ΔEN for the bonded atoms? Why?

Skill-Building Exercises (grouped in similar pairs)

9.56 Using the periodic table only, arrange the elements in each set in order of *increasing* EN:

- (a) S, O, Si (b) Mg, P, As

9.57 Using the periodic table only, arrange the elements in each set in order of *increasing* EN:

- (a) I, Br, N (b) Ca, H, F

9.58 Using the periodic table only, arrange the elements in each set in order of *decreasing* EN:

- (a) N, P, Si (b) Ca, Ga, As

9.59 Using the periodic table only, arrange the elements in each set in order of *decreasing* EN:

- (a) Br, Cl, P (b) I, F, O

9.60 Use Figure 9.20 to indicate the polarity of each bond with a *polar arrow*:

- (a) N—B (b) N—O (c) C—S
(d) S—O (e) N—H (f) Cl—O

9.61 Use Figure 9.20 to indicate the polarity of each bond with *partial charges*:

- (a) Br—Cl (b) F—Cl (c) H—O
(d) Se—H (e) As—H (f) S—N

9.62 Which is the more polar bond in each of the following pairs from Problem 9.60: (a) or (b); (c) or (d); (e) or (f)?

9.63 Which is the more polar bond in each of the following pairs from Problem 9.61: (a) or (b); (c) or (d); (e) or (f)?

9.64 Are the bonds in each of the following substances ionic, nonpolar covalent, or polar covalent? Arrange the substances with polar covalent bonds in order of increasing bond polarity:

- (a) S_8 (b) RbCl (c) PF_3
(d) SCl_2 (e) F_2 (f) SF_2

9.65 Are the bonds in each of the following substances ionic, nonpolar covalent, or polar covalent? Arrange the substances

with polar covalent bonds in order of increasing bond polarity:

- (a) KCl (b) P_4
(c) BF_3 (d) SO_2
(e) Br_2 (f) NO_2

9.66 Rank the members of each set of compounds in order of *increasing* ionic character of their bonds. Use *polar arrows* to indicate the bond polarity of each:

- (a) HBr, HCl, HI
(b) H_2O , CH_4 , HF
(c) SCl_2 , PCl_3 , SiCl_4

9.67 Rank the members of each set of compounds in order of *decreasing* ionic character of their bonds. Use *partial charges* to indicate the bond polarity of each:

- (a) PCl_3 , PBr_3 , PF_3
(b) BF_3 , NF_3 , CF_4
(c) SeF_4 , TeF_4 , BrF_3

Problem in Context

9.68 The energy of the C—C bond is 370 kJ/mol, and that of the Cl—Cl bond is 243 kJ/mol. Which of the following values might you expect for the C—Cl bond energy? Explain.

- (a) 613 kJ/mol (sum of the values given)
(b) 127 kJ/mol (difference of the values given)
(c) 306 kJ/mol (average of the values given)
(d) 350 kJ/mol (greater than the average of the values given)

An Introduction to Metallic Bonding

Concept Review Questions

9.69 (a) List four physical characteristics of a solid metal.
(b) List two chemical characteristics of a metallic element.

9.70 Briefly account for the following relative values:

- (a) The melting points of Na and K are 89°C and 63°C , respectively.
(b) The melting points of Li and Be are 180°C and 1287°C , respectively.
(c) Li boils more than 1100°C higher than it melts.

9.71 Magnesium metal is easily deformed by an applied force, whereas magnesium fluoride is shattered. Why do these two solids behave so differently?

Comprehensive Problems

9.72 Geologists have a rule of thumb: when molten rock cools and solidifies, crystals of compounds with the smallest lattice energies appear at the bottom of the mass. Suggest a reason for this.

9.73 Use Lewis electron-dot symbols to represent the formation of
(a) BrF_3 from bromine and fluorine atoms
(b) AlF_3 from aluminum and fluorine atoms

9.74 Even though so much energy is required to form a metal cation with a 2+ charge, the alkaline earth metals form halides with the general formula MX_2 , rather than MX .

(a) Use the following data to calculate ΔH_f° of MgCl :

$$\Delta H_{\text{lattice}}^\circ \text{ of } \text{MgCl} = 783.5 \text{ kJ/mol}$$

- (b) Is MgCl favored energetically relative to Mg and Cl_2 ? Explain.
(c) Use Hess's law to calculate ΔH° for the conversion of MgCl to MgCl_2 and Mg (ΔH_f° of $\text{MgCl}_2 = -641.6 \text{ kJ/mol}$).
(d) Is MgCl favored energetically relative to MgCl_2 ? Explain.

9.75 Gases react explosively if the heat released when the reaction begins is sufficient to cause more reaction, which leads to a rapid expansion of the gases. Use bond energies to calculate ΔH° of each of the following reactions, and predict which occurs explosively:

- (a) $\text{H}_2(\text{g}) + \text{Cl}_2(\text{g}) \longrightarrow 2\text{HCl}(\text{g})$
 (b) $\text{H}_2(\text{g}) + \text{I}_2(\text{g}) \longrightarrow 2\text{HI}(\text{g})$
 (c) $2\text{H}_2(\text{g}) + \text{O}_2(\text{g}) \longrightarrow 2\text{H}_2\text{O}(\text{g})$

9.76 By using photons of specific wavelengths, chemists can dissociate gaseous HI to produce H atoms with certain speeds. When HI dissociates, the H atoms move away rapidly, whereas the heavier I atoms move more slowly.

- (a) What is the longest wavelength (in nm) that can dissociate a molecule of HI?
 (b) If a photon of 254 nm is used, what is the excess energy (in J) over that needed for dissociation?
 (c) If this excess energy is carried away by the H atom as kinetic energy, what is its speed (in m/s)?

9.77 In developing the concept of electronegativity, Pauling used the term *excess bond energy* for the difference between the actual bond energy of X—Y and the average bond energies of X—X and Y—Y (see the discussion of HF in Section 9.5). Based on the values in Figure 9.20, which of the following substances contain bonds with no excess bond energy?

- (a) PH_3 (b) CS_2 (c) BrCl (d) BH_3 (e) Se_8

9.78 Use condensed electron configurations to predict the relative hardnesses and melting points of rubidium ($Z = 37$), vanadium ($Z = 23$), and cadmium ($Z = 48$).

9.79 Without stratospheric ozone (O_3), harmful solar radiation would cause gene alterations. Ozone forms when the bond in O_2 breaks and each O atom reacts with another O_2 molecule. It is destroyed by reaction with the Cl atoms formed when the C—Cl bond in synthetic chemicals breaks. Find the wavelengths of light that can break the C—Cl bond and the bond in O_2 .

9.80 “Inert” xenon actually forms many compounds, especially with highly electronegative fluorine. The ΔH_f° values for xenon difluoride, tetrafluoride, and hexafluoride are -105 , -284 , and -402 kJ/mol, respectively. Find the average bond energy of the Xe—F bonds in each fluoride.

9.81 The HF bond length is 92 pm, 16% shorter than the sum of the covalent radii of H (37 pm) and F (72 pm). Suggest a reason for this difference. Similar data show that the difference becomes smaller down the group, from HF to HI. Explain.

9.82 There are two main types of covalent bond breakage. In homolytic breakage (as in Table 9.2), each atom in the bond gets one of the shared electrons. In some cases, the electronegativity of adjacent atoms affects the bond energy. In heterolytic breakage, one atom gets both electrons and the other gets none; thus, a cation and an anion form.

- (a) Why is the C—C bond in $\text{H}_3\text{C—CF}_3$ (423 kJ/mol) stronger than that in $\text{H}_3\text{C—CH}_3$ (376 kJ/mol)?
 (b) Use bond energy and any other data to calculate the enthalpy of reaction for the heterolytic cleavage of O_2 .

9.83 Find the longest wavelengths of light that can cleave the bonds in elemental nitrogen, oxygen, and fluorine.

9.84 The work function (ϕ) of a metal is the minimum energy needed to remove an electron from its surface.

- (a) Is it easier to remove an electron from a gaseous silver atom or from the surface of solid silver ($\phi = 7.59 \times 10^{-19}$ J; $\text{IE} = 731$ kJ/mol)?
 (b) Explain the results in terms of the electron-sea model of metallic bonding.

9.85 Lattice energies can also be calculated for covalent network solids using a Born-Haber cycle, and the network solid silicon dioxide has one of the highest $\Delta H_{\text{lattice}}^\circ$ values. Silicon dioxide is found in pure crystalline form as transparent rock quartz. Much harder than glass, this material was once prized for making lenses for optical devices and expensive spectacles. Use Appendix B and the following data to calculate $\Delta H_{\text{lattice}}^\circ$ of SiO_2 :

9.86 The average C—H bond energy in CH_4 is 415 kJ/mol. Use Table 9.2 and the following data to calculate the average C—H bond energy in ethane (C_2H_6 ; C—C bond), in ethene (C_2H_4 ; C=C bond), and in ethyne (C_2H_2 ; C≡C bond):

9.87 Carbon-carbon bonds form the “backbone” of nearly every organic and biological molecule. The average bond energy of the C—C bond is 370 kJ/mol. Calculate the frequency and wavelength of the least energetic photon that can break an average C—C bond. In what region of the electromagnetic spectrum is this radiation?

9.88 In a future hydrogen-fuel economy, the cheapest source of H_2 will certainly be water. It takes 497 kJ to produce 1 mol of H atoms from water. What are the frequency, wavelength, and minimum energy of a photon that can free an H atom from water?

9.89 Ethanol ($\text{CH}_3\text{CH}_2\text{OH}$) and dimethyl ether (CH_3OCH_3) have the same molecular formula, but different arrangements of bonds:

- (a) Use Table 9.2 to calculate $\Delta H_{\text{rxn}}^\circ$ for the formation of each compound as a gas from methane (CH_4) and oxygen; water vapor also forms.
 (b) State which reaction is more exothermic.
 (c) Calculate $\Delta H_{\text{rxn}}^\circ$ for the conversion of ethanol to dimethyl ether.

9.90 Enthalpies of reaction calculated from bond energies and from enthalpies of formation are often, but not always, close to each other.

- (a) Industrial ethanol ($\text{CH}_3\text{CH}_2\text{OH}$) is produced by a catalytic reaction of ethylene ($\text{CH}_2=\text{CH}_2$) with water at high pressures and temperatures. Calculate $\Delta H_{\text{rxn}}^\circ$ for this gas-phase hydration of ethylene to ethanol, using bond energies and then using enthalpies of formation.
 (b) Ethylene glycol is produced by the catalytic oxidation of ethylene to ethylene oxide, which then reacts with water to form ethylene glycol:

The $\Delta H_{\text{rxn}}^\circ$ for this hydrolysis step, based on enthalpies of formation, is -97 kJ/mol. Calculate $\Delta H_{\text{rxn}}^\circ$ for the hydrolysis using bond energies.

- (c) Why are the two values relatively close for the hydration in part (a) but not close for the hydrolysis in part (b)?

Most people love the taste of sugar, but don't love the calories that result from enjoying sugary treats and sodas. Thus, in many food products, such as diet sodas, sugar is replaced with artificial sweeteners such as aspartame and sucralose. These compounds taste sweet to us because their molecular shapes allow them to “fit” into the taste bud receptors in our tongues that signal the sweetness of sugar. The three-dimensional shape of a molecule can affect its role in chemical reactions and is an important consideration in the discovery of new pharmaceutical drugs. All the symbols, lines, and dots you've been seeing in representations of molecules thus far make it easy to forget that every molecule has a characteristic minute, three-dimensional architecture, with each atom, bonding pair, and lone pair of electrons in a specific position relative to the others. Let's focus now on examining the three-dimensional features of molecules.

IN THIS CHAPTER . . . *We learn how to picture a molecule by writing a two-dimensional structure for it and converting it to a three-dimensional shape, and we examine some effects of molecular shape on physical and biochemical behavior.*

- › We learn how to apply the octet rule to convert a molecular formula into a flat structural formula that shows atom attachments and electron-pair locations.
- › We see how electron delocalization limits our ability to depict a molecule with a single structural formula and requires us to apply the concept of resonance.
- › We introduce bond angle and apply a theory that converts two-dimensional formulas into three-dimensional shapes.
- › We describe five basic classes of shapes that many molecules adopt and consider how multiple bonds and lone pairs affect them and how to combine smaller molecular portions into the shapes of more complex molecules.
- › We discuss the relation among bond polarity, shape, and molecular polarity and the effect of polarity on behavior.
- › We describe a few examples of the influence of shape on biological function.

10.1 DEPICTING MOLECULES AND IONS WITH LEWIS STRUCTURES

The first step toward visualizing a molecule is to convert its molecular formula to its **Lewis structure** (or **Lewis formula***), which shows symbols for the atoms, the bonding electron pairs as lines, and the lone electron pairs that fill each atom's outer level (valence shell) as pairs of dots.

Applying the Octet Rule to Write Lewis Structures

To write a Lewis structure, we decide on the relative placement of the atoms in the molecule or polyatomic ion and then distribute the total number of valence electrons as bonding and lone pairs. In many, but not all, cases, the octet rule (Section 9.1)

*A Lewis *structure* does **not** indicate the three-dimensional shape, so it may be more correct to call it a Lewis *formula*, but we follow convention and use the term *structure*.

A Species with single bonds only

B Species with multiple bonds

Figure 10.1 The steps in converting a molecular formula into a Lewis structure.

guides us in distributing the electrons. Recall that the shared (bonding) electrons are counted as part of the octet of each atom in the bond, whereas lone pairs are counted only by the atom to which they belong. We begin with species that “obey” the octet rule, in which each atom fills its outer level with eight electrons (or two for hydrogen).

Molecules with Single Bonds Figure 10.1A shows the four steps for writing Lewis structures for species with only single bonds. Let’s use two species, nitrogen trifluoride, NF_3 , and the tetrafluoroborate ion, BF_4^- , to introduce the steps:

Step	NF_3	BF_4^-
Step 1. Place the atoms relative to each other. For the general molecular formula AB_n : - Place atom with the lower group number in the center (usually the atom with the lower electronegativity, EN) - If the atoms in the species have the same group number, place the atom with the higher period number (also the lower EN) in the center. - H can form only one bond, so it is never in the center.	N (Group 15) has a lower group number than F (Group 17), so it goes in the center with the three F atoms around it: $\begin{array}{c} \text{F} \\ \\ \text{F} - \text{N} - \text{F} \end{array}$	B (Group 13) has a lower group number than F (Group 17), so it goes in the center with the four F atoms around it: $\begin{array}{c} \text{F} \\ \\ \text{F} - \text{B} - \text{F} \\ \\ \text{F} \end{array}$
Step 2. Determine the number of valence electrons. <i>Molecules:</i> The group number indicates the number of valence electrons: Group 13 = 3 valence e^-, Group 14 = 4 valence e^-, etc. <i>Ions:</i> Add one e^- for each negative charge or subtract one e^- for each positive charge.	N: Group 15: 5 valence e^- F: Group 17: 7 valence e^- N: $1 \times 5 = 5e^-$ F: $3 \times 7 = 21e^-$ Total = $26e^-$	B: Group 13: 3 valence e^- F: Group 17: 7 valence e^- B: $1 \times 3 = 3e^-$ F: $4 \times 7 = 28e^-$ charge: = $1e^-$ Total = $32e^-$
Step 3. Draw single bonds between the atoms and subtract $2e^-$ for each bond from the total number of valence electrons.	The completed Lewis structure <i>must</i> contain exactly $26e^-$. $\begin{array}{c} \text{F} \\ \\ \text{F} - \text{N} - \text{F} \end{array}$ 3 N—F bonds $\times 2e^- = 6e^-$ $26e^- - 6e^- = 20e^-$ remaining	The completed Lewis structure <i>must</i> contain exactly $32e^-$. $\begin{array}{c} \text{F} \\ \\ \text{F} - \text{B} - \text{F} \\ \\ \text{F} \end{array}$ 4 B—F bonds $\times 2e^- = 8e^-$ $32e^- - 8e^- = 24e^-$ remaining

Step 4. Distribute remaining electrons in pairs so that each atom has a total of 8e⁻ (2e⁻ for H).

- Place lone pairs on surrounding (more electronegative) atoms first to give each an octet.
- If any electrons remain, place them around the central atom.

$$\begin{array}{l} \text{F: three pairs each:} \\ 3 \times 6e^- = 18e^- \\ \text{N: one pair:} \\ 1 \times 2e^- = 2e^- \\ \hline \text{Total} = 20e^- \end{array}$$

$$\begin{array}{l} \text{F: three pairs each:} \\ 4 \times 6e^- = 24e^- \\ \text{B: no electrons} \\ \text{(already has} \\ \text{an octet): } 0 \times 2e^- = 0e^- \\ \hline \text{Total} = 24e^- \end{array}$$

Check the structure.

- Ensure that all valence e⁻ are used—no less and no more.
- Ensure that each atom has an octet (8e⁻; 2e⁻ for H).
- For ions, put the structure in brackets with the ion charge as a superscript outside the brackets.

$$\begin{array}{l} 6e^- \text{ in three bonds} \\ + 20e^- \text{ in 10 lone pairs} \\ \hline 26 \text{ valence electrons} \end{array}$$

Note: Lewis structures do not indicate shape, so an equally correct depiction of NF₃ is

or any other that retains the same connections among the atoms.

$$\begin{array}{l} 8e^- \text{ in four bonds} \\ + 24e^- \text{ in 12 lone pairs} \\ \hline 32 \text{ valence electrons} \end{array}$$

Using these four steps, you can write a Lewis structure for any *singly bonded* species with a central C, N, or O atom, as well as for some species with central atoms from higher periods. In nearly all their compounds,

- Hydrogen atoms form one bond.
- Carbon atoms form four bonds.
- Nitrogen atoms form three bonds.
- Oxygen atoms form two bonds.
- Surrounding halogens form one bond; fluorine is *always* a surrounding atom.

**Student Hot Spot**

Student data indicate that you may struggle with drawing Lewis structures. Access the eBook to view an additional Learning Resource video on this topic.

SAMPLE PROBLEM 10.1**Writing Lewis Structures for Species with Single Bonds and One Central Atom**

Problem Write a Lewis structure for (a) CCl₂F₂; (b) PCl₂.

Solution (a) *Step 1.* Place the atoms relative to each other. In CCl₂F₂, carbon has the lowest group number and EN, so it is the central atom. The halogen atoms surround it, but their specific positions are not important.

Step 2. Determine the total number of valence electrons: C is in Group 14; F and Cl are in Group 17. Therefore, we have

$$[1 \times \text{C}(4e^-)] + [2 \times \text{F}(7e^-)] + [2 \times \text{Cl}(7e^-)] = 32 \text{ valence } e^-$$

Step 3. Draw single bonds to the central atom and subtract 2e⁻ for each bond:

$$4 \text{ bonds} \times 2e^- = 8e^- \quad 32e^- - 8e^- = 24e^- \text{ remaining}$$

Step 4. Distribute the 24 remaining electrons in pairs, beginning with the surrounding atoms, so that each atom has an octet. Each surrounding fluorine and chlorine atom gets three pairs (4 × 6e⁻ = 24e⁻). All atoms have an octet of electrons.

(b) *Step 1.* Place the atoms relative to each other. In PCl₂, phosphorus has the lower group number and EN, so it is the central atom. The chlorine atoms surround it.

Step 2. Determine the total number of valence electrons: P is in Group 15, and Cl is in Group 17. Add $1e^-$ to the total number of valence electrons because of the $1-$ charge:

$$[1 \times P(5e^-)] + [2 \times Cl(7e^-)] + [\text{charge}(1e^-)] = 20 \text{ valence } e^-$$

Step 3: $Cl-P-Cl$

Step 3. Draw single bonds to the central atom and subtract $2e^-$ for each bond:

$$2 \text{ bonds} \times 2e^- = 4e^- \quad 20e^- - 4e^- = 16e^- \text{ remaining}$$

Step 4: $[\text{:}\ddot{Cl}-\ddot{P}-\ddot{Cl}\text{:}]^-$

Step 4. Distribute the 16 remaining electrons in pairs, beginning with the surrounding atoms, so that each atom has an octet. Each surrounding chlorine atom gets three pairs, and the central phosphorus atom gets two pairs ($Cl: 2 \times 6e^- = 12e^-$; $P: 1 \times 4e^- = 4e^-$; total = $16e^-$). Each atom has an octet of electrons. Since this species is an ion, place brackets around the Lewis structure and indicate the $1-$ charge as a superscript negative sign outside the brackets.

Check Always check that each atom has an octet. Bonding electrons belong to each atom in the bond. In CCl_2F_2 , the total number in bonds ($8e^-$) and lone pairs ($24e^-$) equals 32 valence e^- . As expected, C has four bonds and each of the surrounding halogens has one bond. In PCl_2^- , the total number of electrons in bonds ($4e^-$) and lone pairs ($16e^-$) equals 20 valence e^- .

FOLLOW-UP PROBLEMS

Brief Solutions to all Follow-up Problems appear at the end of the chapter.

10.1A Write a Lewis structure for (a) H_2S ; (b) $AlCl_4^-$; (c) $SOCl_2$.

10.1B Write a Lewis structure for (a) OF_2 ; (b) CH_2Br_2 ; (c) IBr_2^+ .

SOME SIMILAR PROBLEMS 10.5(a), 10.5(b), 10.6(a), 10.6(c), 10.7(a), and 10.8(c)

In molecules with two or more central atoms bonded to each other, it is usually clear which atoms are central and which are surrounding.

SAMPLE PROBLEM 10.2

Writing Lewis Structures for Molecules with Single Bonds and More Than One Central Atom

Problem Write the Lewis structure for methanol (molecular formula CH_4O), an important industrial alcohol that can be used as a gasoline alternative in cars.

Solution **Step 1.** Place the atoms relative to each other. The H atoms can have only one bond, so C and O must be central and adjacent to each other. C has four bonds and O has two, so we arrange the H atoms accordingly.

Step 1: $\begin{array}{ccccc} & H & & & \\ & | & & & \\ H & C & O & H & \\ & | & & & \\ & H & & & \end{array}$

Step 2. Find the sum of valence electrons (C is in Group 14; O is in Group 16; H is in Group 1):

$$[1 \times C(4e^-)] + [1 \times O(6e^-)] + [4 \times H(1e^-)] = 14e^-$$

Step 3: $\begin{array}{c} H \\ | \\ H-C-O-H \\ | \\ H \end{array}$

Step 3. Add single bonds and subtract $2e^-$ for each bond:

$$5 \text{ bonds} \times 2e^- = 10e^- \quad 14e^- - 10e^- = 4e^- \text{ remaining}$$

Step 4. Add the remaining four electrons in pairs to fill each valence level. C already has an octet, and each H shares $2e^-$ with the C; so the remaining $4e^-$ form two lone pairs on O to give the Lewis structure for methanol.

Step 4: $\begin{array}{c} H \\ | \\ H-C-\ddot{O}-H \\ | \\ H \end{array}$

Check Each H atom has $2e^-$, and C and O each have $8e^-$. The total number of valence electrons is $14e^-$, which equals $10e^-$ in bonds plus $4e^-$ in two lone pairs. Each H has one bond, C has four, and O has two.

FOLLOW-UP PROBLEMS

10.2A Write a Lewis structure for (a) hydroxylamine (NH_3O); (b) dimethyl ether (C_2H_6O ; no $O-H$ bonds).

10.2B Write a Lewis structure for (a) hydrazine (N_2H_4); (b) methylamine (CH_3NH_2).

SOME SIMILAR PROBLEMS 10.8(a) and 10.8(b)

Molecules with Multiple Bonds After completing steps 1–4 to write the Lewis structure for a species, we may find that the central atom still does not have an octet.

In most of these cases, we need an additional step, Step 5 (Figure 10.1B). Let's draw the Lewis structure for the HCN molecule to illustrate this:

Step	HCN
Step 1. Place the atoms relative to each other. H can form only one bond, so it is never in the center.	C (Group 14) has a lower group number than N (Group 15), so it goes in the center with the H and N atoms around it: $\text{H} \quad \text{C} \quad \text{N}$
Step 2. Determine the number of valence electrons.	H: Group 1: 1 valence e^- ; $1 \times 1e^- = 1e^-$ C: Group 14: 4 valence e^- ; $1 \times 4e^- = 4e^-$ N: Group 15: 5 valence e^- ; $1 \times 5e^- = 5e^-$ $\text{Total} = 10e^-$
Step 3. Draw single bonds between the atoms and subtract $2e^-$ for each bond from the total number of valence electrons.	$\text{H}-\text{C}-\text{N}$ $\begin{array}{l} 1 \text{ H}-\text{C} \text{ bond} \times 2e^- = 2e^- \\ 1 \text{ C}-\text{N} \text{ bond} \times 2e^- = 2e^- \\ \hline \text{Total:} \quad \quad \quad = 4e^- \\ 10e^- - 4e^- = 6e^- \text{ remaining} \end{array}$
Step 4. Distribute remaining electrons in pairs so that each atom has a total of $8e^-$ ($2e^-$ for H). Place lone pairs on surrounding (more electronegative) atoms first to give each an octet.	$\text{H}-\text{C}-\ddot{\text{N}}:$ N: three pairs: $1 \times 6e^- = 6e^-$ The 6 remaining electrons are enough for N to complete its octet, but there are not enough electrons to give C an octet; so Step 5 is necessary.
Step 5. Form one or more multiple bonds. Change a lone pair on a surrounding atom into another bonding pair to the central atom, thus forming a double bond. This can be done again if necessary to form a triple bond or another double bond until the central atom has an octet.	$\text{H}-\text{C}-\ddot{\text{N}}:$ Since C needs four more electrons to obtain an octet, two lone pairs on the N atom are changed to two additional bonding pairs, for a triple bond: $\text{H}-\text{C}\equiv\text{N}:$ $\begin{array}{l} 8e^- \text{ in four bonds} \\ + 2e^- \text{ in 1 lone pair} \\ \hline 10 \text{ valence electrons} \end{array}$

SAMPLE PROBLEM 10.3

Writing Lewis Structures for Molecules with Multiple Bonds

Problem Write Lewis structures for the following:

(a) Ethylene (C_2H_4), the most important reactant in the manufacture of polymers

(b) Nitrogen (N_2), the most abundant atmospheric gas

Solution (a) *Step 1.* Place the atoms relative to each other. In C_2H_4 , the two C atoms must be bonded to each other since H atoms can have only one bond.

Step 2. Determine the total number of valence electrons (C is in Group 14; H is in Group 1):

$$[2 \times \text{C}(4e^-)] + [4 \times \text{H}(1e^-)] = 12 \text{ valence } e^-$$

Step 3. Add single bonds and subtract $2e^-$ for each bond:

$$5 \text{ bonds} \times 2e^- = 10e^- \quad \text{so} \quad 12e^- - 10e^- = 2e^- \text{ remaining}$$

Step 4. Distribute the remaining valence electrons to attain octets.

Step 5. Change a lone pair to a bonding pair. The right C has an octet, but the left C has only $6e^-$, so we change the lone pair on the right C to another bonding pair between the two C atoms.

(b) *Step 1.* Place the atoms relative to each other.

Step 2. Determine the total number of valence electrons (N is in Group 15):

$$[2 \times \text{N}(5e^-)] = 10 \text{ valence } e^-$$

Step 3. Add single bonds and subtract $2e^-$ for each bond:

$$1 \text{ bond} \times 2e^- = 2e^- \quad 10e^- - 2e^- = 8e^- \text{ remaining}$$

(a) C_2H_4

(b) N_2

Step 4. Distribute the remaining valence electrons to attain octets.

Step 5. The N on the left ends up with an octet, but the N on the right does not, so we change a lone pair to a bonding pair. In this case, moving one lone pair to make a double bond still does not give both N atoms an octet, so we move a second lone pair to make a triple bond.

Check (a) Each C has four bonds and counts the $4e^-$ in the double bond as part of its own octet. The valence electron total is $12e^-$, all in six bonds. (b) Each N counts the $6e^-$ in the triple bond as part of its own octet. The valence electron total is $10e^-$, which equals the electrons in three bonds and two lone pairs.

FOLLOW-UP PROBLEMS

10.3A Write Lewis structures for (a) CO (the only common molecule in which C has three bonds); (b) O_2 ; (c) CO_2 .

10.3B Write Lewis structures for (a) NO^+ ; (b) H_2CO ; (c) N_2H_2 .

SOME SIMILAR PROBLEMS 10.5(c), 10.6(b), 10.7(b), and 10.7(c)

Resonance: Delocalized Electron-Pair Bonding

We often find that we can write more than one Lewis structure for a molecule or polyatomic ion, where only the placement of the electrons differs. Which, if any, is correct?

The Need for Resonance Structures Let's consider the Lewis structure for ozone, O_3 .

- Since oxygen is in Group 16, there are $3 \times 6e^- = 18$ valence e^- in the molecule.
- Four electrons are used in the formation of two single O—O bonds, leaving $18e^- - 4e^- = 14e^-$.
- The remaining $14e^-$ are enough to give the surrounding O atoms (designated A and C for clarity) an octet of electrons, but not enough to complete the octet of the central O atom (designated B).
- Applying Step 5 gives two Lewis structures for the same molecule, one in which the double bond involves oxygen A and oxygen B (structure I) and one in which the double bond involves oxygen B and oxygen C (structure II).

In structure I, a lone pair on oxygen A is changed to another bonding pair so that oxygen B has a double bond to oxygen A and a single bond to oxygen C. In structure II, the single and double bonds are reversed as a lone pair on oxygen C is changed to a bonding pair. You can rotate I to get II, so these are *not* different types of ozone molecules but different Lewis structures for the *same* molecule.

Comparing the bond lengths in Lewis structures I and II with the length of the actual bonds in O_3 results in an interesting observation:

Lewis structures I and II:	one O=O double bond with bond length of 121 pm
	one O—O single bond with bond length of 148 pm
O_3 molecule:	two oxygen-oxygen bonds that are identical in length (128 pm) and energy

We explain this discrepancy as follows:

- Each bond in O_3 has properties between those of an O—O bond and an O=O bond, making it something like a “one-and-a-half” bond.
- The molecule is shown more correctly as two Lewis structures, called **resonance structures**, with a two-headed resonance arrow ($\longleftrightarrow$) between them.
- Resonance structures *have the same relative placement of atoms but different locations of bonding and lone electron pairs*. You can convert one resonance form to another by moving lone pairs to bonding positions, and vice versa:

- *Resonance structures are not real bonding depictions:* O_3 does *not* change back and forth quickly from structure I to structure II. The actual molecule is a **resonance hybrid**, an average of the resonance structures. ◀

Electron Delocalization Our need for more than one Lewis structure to depict O_3 is due to **electron-pair delocalization**. In a single, double, or triple bond, each electron pair is *localized* between the bonded atoms. In a resonance hybrid, two of the electron pairs (one bonding and one lone pair) are *delocalized*: their density is “spread” over a few adjacent atoms. (This delocalization involves just a few e^- pairs, so it is *much* less extensive than the electron delocalization in metals that we considered in Section 9.6.)

In O_3 , the result is two identical bonds, each consisting of a single bond (the localized pair) and a *partial bond* (the contribution from one of the delocalized pairs). We draw the resonance hybrid with a curved dashed line to show the delocalized pairs:

Resonance is very common. For example, benzene (C_6H_6 , shown below) has two important resonance structures in which alternating single and double bonds have different positions. The actual molecule is an average of the two structures, with six carbon-carbon bonds of equal length and three electron pairs delocalized over all six C atoms. The delocalized pairs are often shown as a dashed circle (or simply a circle):

It is difficult to depict species such as O_3 and C_6H_6 with a single Lewis structure—how do we adequately depict partial bonds? Therefore we use individual resonance structures that do not actually exist to represent the species, keeping in mind that the actual species is an average of the resonance structures.

Fractional Bond Orders Partial bonding, as in resonance hybrids, often leads to fractional bond orders. For O_3 , which has a total of three bonds (shared electron pairs) between two bonded-atom ($\text{O}-\text{O}$) pairs, we have

$$\text{Bond order} = \frac{3 \text{ shared electron pairs}}{2 \text{ bonded-atom (O—O) pairs}} = 1\frac{1}{2}$$

The bond order in the benzene ring is 9 shared electron pairs/6 bonded-atom ($\text{C}-\text{C}$) pairs, or $1\frac{1}{2}$ also. For the carbonate ion, CO_3^{2-} , three resonance structures can be drawn:

Each has 4 electron pairs shared among 3 bonded-atom ($\text{C}-\text{O}$) pairs, so the bond order is $\frac{4}{3}$, or $1\frac{1}{3}$.

A Purple Mule, Not a Blue Horse and a Red Donkey

A mule is a genetic mix, a hybrid, of a horse and a donkey; it is not a horse one instant and a donkey the next. Similarly, the color purple is a mix of red and blue, not red one instant and blue the next. In the same sense, a resonance hybrid is one molecular species, not one resonance structure this instant and another resonance structure the next. The problem is that we cannot depict the actual species, the hybrid, accurately with a single Lewis structure.

Student Hot Spot

Student data indicate that you may struggle with the concept of resonance. Access the eBook to view an additional Learning Resource video on this topic.

Formal Charge: Selecting the More Important Resonance Structure

As we have seen, a resonance hybrid is the average of the resonance structures that we can write for a species. If one resonance structure “looks” more like the resonance hybrid than the others, it “weights” the average in its favor. One way to select the more important resonance structure is by determining each atom’s **formal charge**, the charge it would have *if the bonding electrons were shared equally*. We’ll examine this concept and then see how formal charge compares with oxidation number.

Determining Formal Charge An atom’s formal charge is its total number of valence electrons minus the number of electrons associated with that atom in the Lewis structure: *all* of its unshared valence electrons and *half* of its shared valence electrons:

$$\text{Formal charge of atom} = \text{no. of valence } e^- - (\text{no. of unshared valence } e^- + \frac{1}{2} \text{ no. of shared valence } e^-) \quad (10.1)$$

For example, in O_3 , the formal charge of oxygen A in resonance structure I is

$$6 \text{ valence } e^- - (4 \text{ unshared } e^- + \frac{1}{2} \text{ of } 4 \text{ shared } e^-) = 6 - 4 - 2 = 0$$

The formal charges of all the atoms in the two O_3 resonance structures are

Structures I and II have the same formal charges but on different O atoms, so they contribute equally to the resonance hybrid. We can make the following observations about formal charges:

- If the number of electrons associated with an atom in the Lewis structure equals the number of valence electrons in the isolated atom, its formal charge is 0.
- If the number of electrons associated with an atom in the Lewis structure is greater than the number of valence electrons in the isolated atom, its formal charge is negative.
- If the number of electrons associated with an atom in the Lewis structure is less than the number of valence electrons in the isolated atom, its formal charge is positive.
- Formal charges must sum to the actual charge on the species: zero for a molecule or the ionic charge for an ion. In O_3 , the formal charges add to 0: $(+1) + (-1) + 0 = 0$.
- Only when an atom has a zero formal charge does it have its usual number of bonds. Note that, in structure I, only O_A has oxygen’s usual two bonds; O_B has three bonds and O_C has one.

Choosing the More Important Resonance Structure Three criteria help us choose the more important resonance structure:

- Smaller formal charges (positive *or* negative) are preferable to larger ones.
- The *same* nonzero formal charges on adjacent atoms are not preferred.
- A more negative formal charge should reside on a more electronegative atom.

As in the case of O_3 , the resonance structures for CO_3^{2-} and benzene both have identical atoms surrounding the central atom(s) and, thus, have identical formal charges and are equally important contributors to the resonance hybrid. But let’s apply these criteria to the cyanate ion, NCO^- , which has two *different* atoms around the central one. After distributing the valence electrons to the atoms in the ion, the C atom

does not have an octet. Three resonance structures (with formal charges) may be drawn (see margin):

From the formal charges, we can draw the following conclusions:

- Structure I is *not* an important contributor to the hybrid because it has a larger formal charge on N and a positive formal charge on the more electronegative O.
- Structures II and III have the same magnitude of charges, but III has a -1 formal charge on O, the more electronegative atom.
- Therefore, II and III are more important than I, and III is more important than II. This means that the bond between C and N should have a significant amount of triple bond character, as in structure III. The bond length between C and N in this ion is 117 pm, slightly longer than a typical $\text{C}\equiv\text{N}$ bond (115 pm).

Note that the formal charges in each structure sum to -1 , the charge of the ion.

Formal Charge vs. Oxidation Number Formal charge (used to examine resonance structures) is *not* the same as oxidation number (used to monitor redox reactions):

- For a *formal charge*, bonding electrons are *shared equally* by the atoms (as if the bonding were *nonpolar covalent*), so each atom has half of them:

$$\text{Formal charge} = \text{valence } e^- - (\text{unshared } e^- + \frac{1}{2} \text{ shared } e^-)$$

- For an *oxidation number*, bonding electrons are *transferred completely* to the more electronegative atom (as if the bonding were *pure ionic*):

$$\text{Oxidation number} = \text{valence } e^- - (\text{unshared } e^- + \text{shared } e^-)$$

Compare the two sets of numbers for the three cyanate ion resonance structures. When determining the oxidation numbers of the atoms in this ion, all electrons in the bonds between N and C are assigned to the more electronegative N atom, while all electrons in the bonds between C and O are assigned to the more electronegative O atom. For example, the oxidation number of N in the first resonance structure is

$$5 \text{ valence } e^- - (6 \text{ unshared } e^- + 2 \text{ shared } e^-) = 5 - 6 - 2 = -3$$

Notice that the oxidation numbers *do not* change from one resonance structure to another (because the electronegativities of the atoms *do not* change), but the formal charges *do* change (because the numbers of bonding and lone pairs *do* change). Neither an atom's formal charge nor its oxidation number represents an actual charge on the atom; both of these types of numbers serve simply to keep track of electrons.

Structure I

$$\text{N} [5 - 6 - \frac{1}{2}(2)] = -2$$

$$\text{C} [4 - 0 - \frac{1}{2}(8)] = 0$$

$$\text{O} [6 - 2 - \frac{1}{2}(6)] = +1$$

Structure II

$$\text{N} [5 - 4 - \frac{1}{2}(4)] = -1$$

$$\text{C} [4 - 0 - \frac{1}{2}(8)] = 0$$

$$\text{O} [6 - 4 - \frac{1}{2}(4)] = 0$$

Structure III

$$\text{N} [5 - 2 - \frac{1}{2}(6)] = 0$$

$$\text{C} [4 - 0 - \frac{1}{2}(8)] = 0$$

$$\text{O} [6 - 6 - \frac{1}{2}(2)] = -1$$

Student Hot Spot

Student data indicate that you may struggle with using formal charges to select the more important resonance structure. Access the eBook to view an additional Learning Resource video on this topic.

SAMPLE PROBLEM 10.4

Writing Resonance Structures and Assigning Formal Charges

Problem Write resonance structures for N_2O (one N is the central atom), assign formal charges to the atoms in each resonance structure, and find the bond order. Use formal charges to determine which resonance structure is most important.

Plan We write a Lewis structure, moving lone and bonding pairs to write resonance structures and connecting them with resonance arrows. We use Equation 10.1 to assign formal charges. The bond order is the number of shared electron pairs divided by the number of atom pairs. To determine the most important resonance structure, we look for low formal charges, with the more negative formal charge on the more electronegative atom.

Solution *Steps 1 and 2.* We are told that one N atom is in the center, so the other N atom and the O atom are each bonded to the central N atom. There are $[2 \times \text{N}(5e^-)] + [1 \times \text{O}(6e^-)] = 16$ valence e^- .

Steps 3 and 4 give us

Since the central N has only $4e^-$, we need two more bonds; we can change a lone pair on the other N and on the O to form two double bonds, or we can change two lone pairs on the end N atom to form a triple bond between the two N atoms, or we can change two lone pairs on the O atom to form a triple bond between the N and O atoms to obtain three resonance structures:

Formal charge of atom = no. of valence e^- – (no. of unshared valence $e^- + \frac{1}{2}$ no. of shared valence e^-).

Structure A:

$$\begin{array}{l} \text{Outside N: } [5 - 4 - \frac{1}{2}(4)] = -1 \\ \text{Central N: } [5 - 0 - \frac{1}{2}(8)] = +1 \\ \text{O: } [6 - 4 - \frac{1}{2}(4)] = 0 \end{array}$$

Structure C:

$$\begin{array}{l} \text{Outside N: } [5 - 6 - \frac{1}{2}(2)] = -2 \\ \text{Central N: } [5 - 0 - \frac{1}{2}(8)] = +1 \\ \text{O: } [6 - 2 - \frac{1}{2}(6)] = +1 \end{array}$$

Structure B:

$$\begin{array}{l} \text{Outside N: } [5 - 2 - \frac{1}{2}(6)] = 0 \\ \text{Central N: } [5 - 0 - \frac{1}{2}(8)] = +1 \\ \text{O: } [6 - 6 - \frac{1}{2}(2)] = -1 \end{array}$$

The bond order is

$$\frac{4 \text{ shared electron pairs}}{2 \text{ bonded-atoms pairs}} = 2$$

Structure C has higher formal charges than structures A and B, so structure C is not an important contributor to the resonance hybrid. Structures A and B have the same magnitude of formal charges; since structure B has the negative formal charge on O, the more electronegative atom, **structure B is the most important.**

Check Each structure has the same relative placement of atoms, an octet around each atom, and $16e^-$ (the sum of the valence electrons distributed in four bonds and four lone pairs). Each set of formal charges adds to zero as expected for a molecule.

FOLLOW-UP PROBLEMS

10.4A Write resonance structures for nitromethane, H_3CNO_2 (the H atoms are bonded to C, and the C atom is bonded to N, which is bonded to both O atoms). Assign formal charges to the atoms in each resonance structure.

10.4B Write resonance structures for the thiocyanate ion, SCN^- (C is the central atom). Use formal charges to determine which resonance structure is the most important.

SOME SIMILAR PROBLEMS 10.9–10.16

Lewis Structures for Exceptions to the Octet Rule

The octet rule applies to most molecules (and ions) with Period 2 central atoms, but not every one, and not to many with central atoms from Period 3 and higher. Three important exceptions occur for molecules with (1) electron-deficient atoms, (2) odd-electron atoms, and (3) atoms with expanded valence shells. In discussing these exceptions, you'll also see that formal charge has limitations for selecting the best resonance structure.

Molecules with Electron-Deficient Atoms In gaseous molecules containing either beryllium or boron as the central atom, that atom is often **electron deficient**: it has

fewer than eight electrons around it (an incomplete octet). The Lewis structures, with formal charges, of gaseous beryllium chloride* and boron trifluoride are

There are only four electrons around Be and only six around B. Surrounding halogen atoms don't form multiple bonds to the central atoms to give them an octet, because the halogens are much more electronegative than either Be or B. Formal charges make the following structures unlikely:

(Some data for BF_3 show a shorter than expected B—F bond. Shorter bonds indicate double-bond character, so the structure with the B=F bond may be a minor contributor to a resonance hybrid.) Electron-deficient atoms often attain an octet by forming additional bonds in reactions. When BF_3 reacts with ammonia, for instance, a compound forms in which boron attains an octet:

Molecules with Odd-Electron Atoms A few molecules contain a central atom with an odd number of valence electrons, so they cannot have all their electrons in pairs. Most of these molecules have a central atom from an odd-numbered group, such as N (Group 15) or Cl (Group 17). They are called **free radicals**, species that contain a lone (unpaired) electron, which makes them paramagnetic (Section 8.4) and extremely reactive. Free radicals are dangerous because they can bond to an H atom in a biomolecule and extract it, which forms a new free radical. This step repeats and can disrupt genes and membranes. Recent studies suggest that free radicals may be involved in cancer and even aging. Antioxidants like vitamin E interrupt free-radical proliferation.

Consider the free radical nitrogen dioxide, NO_2 , a major contributor to urban smog that is formed when the NO in auto exhaust is oxidized. NO_2 has several resonance structures. Two of them differ as to which O atom is doubly bonded to the central atom, as in the case of ozone. Two others have the lone electron residing on the N or on an O, so the resonance hybrid has the lone electron delocalized over these two atoms:

Let's see if formal charge considerations help us decide where the lone electron resides most of the time. The structure with it on the singly bonded O has zero formal charges (*right*), while the structure with it on N (*left*) has some nonzero charges. Thus, based on formal charges, the structure on the right is more important. But chemical facts suggest otherwise. Free radicals often react with each other to pair their lone electrons. When two NO_2 molecules react, the lone electrons pair up to form the N—N bond in dinitrogen tetroxide (N_2O_4) and each N attains an octet:

Thus, given the way NO_2 reacts, the lone electron may spend most of its time on N, making *that* resonance structure more important. Apparently, in this case, formal

*Even though beryllium is in Group 2, most Be compounds have considerable covalent bonding. For example, molten BeCl_2 does not conduct electricity, indicating a lack of ions.

charge is not very useful for picking the most important resonance structure; we'll see other cases in the following subsection.

Expanded Valence Shells Many molecules (and ions) have more than eight valence electrons around the central atom. *That atom expands its valence shell to form more bonds, which releases energy.* The central atom must be large and have empty orbitals that can hold the additional pairs. Therefore, **expanded valence shells** (expanded octets) occur only with *nonmetals from Period 3 or higher because they have d orbitals available*. Such a central atom may be bonded to more than four atoms, or to four or fewer.

1. *Central atom bonded to more than four atoms.* When a central atom forms bonds to more than four atoms, it will have more than eight valence electrons. Two common examples are PCl_5 , in which P forms five bonds and therefore has 10 valence electrons, and SF_6 , in which S forms six bonds and has 12 valence electrons:

Note that P and S do not always have expanded octets; in molecules such as PCl_3 and H_2S , these central atoms have the expected octet of valence electrons.

2. *Central atoms bonded to four or fewer atoms.* In some species, a central atom bonded to *four or fewer* atoms has an expanded valence shell. For example, let's consider ClF_3 , chlorine trifluoride. There are 28 valence electrons in a ClF_3 molecule, 6 in the three single $\text{Cl}-\text{F}$ bonds and 20 that complete the octets of the four atoms. The 2 remaining valence electrons are placed on the central Cl, giving it an expanded valence shell of 10 electrons:

In general, just as in ClF_3 , *any valence electrons remaining after completing the octets of all atoms in a species are given to the central atom.*

There are some species with central atoms bonded to four or fewer atoms for which Lewis structures that obey the octet rule can be drawn. But the concept of formal charge can be applied to draw other Lewis structures for these species in which an atom has an expanded valence shell. Some examples follow:

- *Sulfuric acid.* Two resonance structures of H_2SO_4 , with formal charges, are

Structure I obeys the octet rule, but it has several nonzero formal charges. In structure II, two lone pairs from two O atoms have been changed to bonding pairs; now sulfur has 12 electrons (six bonds) around it, but all atoms have zero formal charges. Thus, based on the formal charge rules alone, II contributes more than I to the resonance hybrid. More important than whether rules are followed, structure II is consistent with observation. In gaseous H_2SO_4 , the two sulfur-oxygen bonds *with* an H atom attached to the O are 157 pm long, whereas the two sulfur-oxygen bonds *without* an H attached to O are 142 pm long. This shorter bond length indicates double-bond character, and other measurements indicate greater electron density in the bonds without the attached H.

- **Sulfate ion.** When sulfuric acid loses two H^+ ions, it forms the sulfate ion, SO_4^{2-} . Measurements indicate that all the bonds in SO_4^{2-} are 149 pm long, between the length of an $\text{S}=\text{O}$ bond (~ 142 pm) and that of an $\text{S}-\text{O}$ bond (~ 157 pm). Six of the seven resonance structures consistent with these data have an expanded valence shell and zero formal charges on some of the atoms. Two of those six (*left*) and the one that obeys the octet rule (*right*) are

- **Two sulfur oxides.** Measurements show that the sulfur-oxygen bonds in SO_2 and SO_3 are all approximately 142 pm long, indicating $\text{S}=\text{O}$ bonds. Lewis structures consistent with these data have zero formal charges (*two at left*), but others (*two at right*) obey the octet rule:

3. **Limitations of Lewis structures and formal charge.** Chemistry has been a central science for well over two centuries, yet controversies often arise over interpretation of data, even in established areas like bonding and structure. We've seen that a single Lewis structure often cannot accurately depict a molecule; in such cases, we need several resonance structures to do so.

Formal charge rules have limitations, too. They were not useful in choosing the correct location for the lone electron in NO_2 . And, quantum-mechanical calculations indicate that resonance structures with expanded valence shells that have zero formal charges look *less* like the actual species than structures that follow the octet rule but have higher formal charges. Shorter bonds arise, these findings suggest, not from double-bond character but because the higher formal charges draw the bonded atoms closer. Such considerations favor the octet-rule structures for H_2SO_4 , SO_4^{2-} , SO_2 , and SO_3 . Thus, formal charge may be a useful tool for selecting the most important resonance structure, but it is far from perfect. Nevertheless, while keeping these contrary findings in mind, we will continue to draw structures based on formal charge rules because they provide a simple approach consistent with most experimental data.

SAMPLE PROBLEM 10.5

Writing Lewis Structures for Octet-Rule Exceptions

Problem Write a Lewis structure and identify the octet-rule exception for (a) XeF_4 ; (b) H_3PO_4 (draw two resonance structures and select the more important; all O atoms are bonded to P and three O atoms have H bonded to them); (c) BFCl_2 .

Plan We write each Lewis structure and examine it for exceptions to the octet rule. (a) and (b) The central atoms are in Periods 5 and 3, respectively, so they can have more than an octet. (c) The central atom is B, which can have fewer than an octet of electrons.

Solution (a) XeF_4 has a total of 36 valence electrons: 8 form the bonds and 24 complete the octets of the F atoms. The remaining 4 valence electrons are placed on the central atom, resulting in an *expanded valence shell*:

(b) H_3PO_4 has 32 valence electrons: 14 form bonds and 18 complete the octets of the O and P atoms (structure I, shown with formal charges). Another resonance structure

(structure II) can be drawn in which a lone pair from the O atom with nonzero formal charge is changed to a bonding pair.

Structure I obeys the octet rule but has nonzero formal charges. Structure II has an expanded valence shell with zero formal charges. According to formal charge rules, structure II is the more important structure.

(c) BFCl_2 has 24 valence electrons: 6 form bonds and 18 complete the octets of the F and Cl atoms. This molecule has an *electron-deficient atom (incomplete octet)*; B has only six electrons surrounding it:

Comment In (b), structure II is consistent with bond-length measurements, which show one shorter (152 pm) phosphorus-oxygen bond and three longer (157 pm) ones. Nevertheless, quantum-mechanical calculations show that structure I may be more important.

FOLLOW-UP PROBLEMS

10.5A Write a Lewis structure with minimal formal charges for (a) POCl_3 ; (b) ClO_2 ; (c) IBr_4^- .

10.5B Write a Lewis structure with minimal formal charges for (a) BeH_2 ; (b) I_3^- ; (c) XeO_3 .

SOME SIMILAR PROBLEMS 10.19–10.22

Summary of Section 10.1

- A stepwise process converts a molecular formula into a Lewis structure, a two-dimensional representation of a molecule (or ion) that shows the placement of atoms and the distribution of valence electrons among bonding and lone pairs.
- When two or more Lewis structures can be drawn for the same relative placement of atoms, the actual structure is a hybrid of those resonance structures.
- Formal charges can be useful for choosing the more important contributor to the hybrid, but experimental data always determine the choice.
- Molecules with an electron-deficient atom (central Be or B) or an odd-electron atom (free radicals) have less than an octet around the central atom but often attain an octet in reactions.
- In a molecule (or ion) with a central atom from Period 3 or higher, that atom can have more than eight valence electrons because it is larger and has empty *d* orbitals for expanding its valence shell.

10.2 VALENCE-SHELL ELECTRON-PAIR REPULSION (VSEPR) THEORY

Virtually every biochemical process hinges to a great extent on the shapes of interacting molecules. Every medicine you take, odor you smell, or flavor you taste depends on part or all of one molecule fitting together with another. Biologists have found that complex behaviors in many organisms, such as mating, defense, navigation, and feeding, often depend on one molecule's shape matching that of another. In this section, we discuss a model for predicting the shape of a molecule.

To determine the molecular shape, we will start with the Lewis structure; to convert that two-dimensional structure into a three-dimensional shape, we use

valence-shell electron-pair repulsion (VSEPR) theory. The main idea of this theory is that *each group of valence electrons around a central atom is located as far as possible from the others so that repulsions between electron groups will be minimized.* When using the VSEPR theory, note that:

- only electron groups around the *central* atom affect shape; electrons on atoms other than the central atom do not.
- a “group” of electrons can be a bond of any type (single, double, or triple), a lone (unshared) pair of electrons, or one lone electron.*

Figure 10.2 Electron-group repulsions and molecular shapes. **A**, Five geometric orientations arise when each balloon occupies as much space as possible. **B**, Mutually repelling bonding groups (gray sticks) attach a surrounding atom (dark gray) to the central atom (red). The name is the electron-group arrangement. Source: (A) Stephen Frisch/McGraw Hill

Electron-Group Arrangements and Molecular Shapes

Figure 10.2A uses balloons to show the five geometric patterns that maximize the distance between two, three, four, five, or six electron groups around a central atom. These geometric shapes illustrate the five *electron-group arrangements* seen in the great majority of molecules and polyatomic ions.

Classifying Molecular Shapes We need to make a distinction between the electron-group arrangement of a molecule or ion and its molecular shape:

- The *electron-group arrangement* is defined as the arrangement of bonding groups (shared electron pairs) *and* nonbonding electron groups (unshared electrons) around the central atom.
- The **molecular shape** is the three-dimensional arrangement of the atoms connected by bonding electron groups only.

Figure 10.2B shows the molecular shapes that occur when *all* the surrounding electron groups are *bonding* groups. When the central atom has no nonbonding electron groups, the electron-group arrangement and the molecular shape are the same. When some of the electron groups around the central atom are nonbonding groups, the electron-group arrangement and the molecular shape are different, as we shall see soon. Thus, *the same electron-group arrangement can give rise to different molecular shapes*: some with all bonding groups (as in Figure 10.2B) and others with bonding and nonbonding groups.

To classify molecular shapes, we can assign each a specific AX_mE_n designation, where m and n are integers. In such a designation,

- A is the central atom;
- X is a surrounding atom; and
- E is a nonbonding valence-electron group, either a lone pair or one lone electron.

*The two electron pairs in a double bond (or the three pairs in a triple bond) occupy separate orbitals, but they remain near each other and act as one electron group (Chapter 11).

Figure 10.3 The single molecular shape of the linear electron-group arrangement. The key (bottom) for A, X, and E also refers to Figures 10.4, 10.5, 10.7, and 10.8.

Bond Angle and Deviations from the Ideal Value The **bond angle** is the angle formed by the bonds joining the nuclei of two surrounding atoms to the nucleus of the central atom, which is at the vertex. The angles shown for the shapes in Figure 10.2B are *ideal* bond angles determined by basic geometry alone. We observe them when all the bonding groups are the same and connected to the same type of atom (structure I). When this is not the case, the real bond angles deviate from the ideal angles. Thus, deviations occur when the bonds are not the same (structure II), the surrounding atoms are not the same (structure III), or one or more of the electron groups are nonbonding groups (structure IV). We'll see examples of these deviations among the compounds discussed in this section.

The Molecular Shape with Two Electron Groups (Linear Arrangement)

The one bond angle that maximizes the distance between two electron groups attached to a central atom is 180° ; thus, the two electron groups point in opposite direction in a **linear arrangement**, which results in a molecule with a **linear shape**. Figure 10.3 shows the general form (top) and shape (middle) for VSEPR shape class AX_2 and gives the formulas of a few examples of linear molecules.

The central atoms in both $BeCl_2$ and CO_2 have two electron groups around them and thus both molecules have a linear shape. Recall that, in gaseous Be compounds, Be is electron deficient, with two single bonds around it. In carbon dioxide, the central C atom forms two double bonds with the O atom; each double bond acts as one electron group:

The lone pairs on the O atoms of CO_2 or on the Cl atoms of $BeCl_2$ are *not* involved in the molecular shape: only the two electron groups around the central C or Be atom affect the shape.

Molecular Shapes with Three Electron Groups (Trigonal Planar Arrangement)

Three electron groups around a central atom point to the corners of an equilateral triangle, which gives the **trigonal planar arrangement** and an ideal bond angle of 120° (Figure 10.4). This arrangement has two molecular shapes—one with all bonding groups and the other with one lone pair. In this case, we can see *the effects of lone pairs and double bonds on bond angles*.

1. *Three bonding groups: trigonal planar shape (AX_3)*. Boron trifluoride (BF_3), another electron-deficient species, is an example of a trigonal planar molecule. It has six electrons around the central B atom in three single bonds to F atoms. The four nuclei lie in a plane, and each F—B—F angle is 120° :

Figure 10.4 The two molecular shapes of the trigonal planar electron-group arrangement.

The nitrate ion (NO_3^-) is one of several polyatomic ions with the trigonal planar shape. One of three resonance structures of the nitrate ion is

Any of the three resonance structures of NO_3^- can be used to determine its molecular shape. Remember that the resonance hybrid has three identical bonds with bond order $1\frac{1}{3}$, so the ideal bond angle is observed.

2. *Two bonding groups and one lone pair: bent (AX_2E).* Sulfur dioxide, SO_2 , like BF_3 , has three electron groups in a trigonal plane, but one of the groups is a lone pair at any one of the triangle's corners. Therefore, the molecular shape is **bent**. A lone pair often has a major effect on bond angle. Because it is held by only one nucleus, a lone pair is less confined than a bonding pair and so exerts stronger repulsions. In general, *a lone pair repels bonding pairs more than bonding pairs repel each other, so it decreases the angle between bonding pairs*. Note the 119° bond angle in SO_2 , which is less than the ideal 120° :

Effect of Double Bonds on Bond Angle When the surrounding atoms and electron groups are not identical, the bond angles are often affected. Consider formaldehyde (CH_2O), whose uses include the manufacture of countertops and the production of methanol. The three electron groups around the central C (all bonding groups) result in a trigonal planar shape. But there are two types of surrounding atoms (O and H) and two types of electron groups (single and double bonds):

The actual $\text{H}-\text{C}-\text{H}$ bond angle is less than the ideal 120° because *the greater electron density of a double bond repels electrons in single bonds more than the single bonds repel each other*.

Molecular Shapes with Four Electron Groups (Tetrahedral Arrangement)

Shapes based on two or three electron groups lie in a plane, but four electron groups require three dimensions to maximize separation. Consider methane, whose Lewis structure (*below, left*) shows four bonds pointing to the corners of a square, which suggests 90° bond angles. But *Lewis structures do not depict shape*. In three dimensions, the four electron groups lie at the corners of a *tetrahedron*, a polyhedron with four faces made of equilateral triangles, giving bond angles of 109.5° (Figure 10.5).

A perspective drawing for methane (*above, middle*) indicates depth by using solid and dashed wedges for bonds out of the plane of the page. The normal bond lines (*blue*) are in the plane of the page; the solid wedge (*green*) is the bond from the C atom in the plane of the page to the H above that plane; and the dashed wedge (*red*) is the bond from the C to the H below the plane of the page. The ball-and-stick model (*above, right*) shows the tetrahedral shape more clearly.

TETRAHEDRAL ELECTRON-GROUP ARRANGEMENT	
Class	Shape
AX_4	 Tetrahedral
Examples: CH_4 , SiCl_4 , SO_4^{2-} , ClO_4^-	
AX_3E	 Trigonal pyramidal
Examples: NH_3 , PF_3 , ClO_3^- , H_3O^+	
AX_2E_2	 Bent
Examples: H_2O , OF_2 , SCl_2	

Figure 10.5 The three molecular shapes of the tetrahedral electron-group arrangement.

Figure 10.6 Lewis structures do not indicate molecular shape. In this model, Cl is green and F is yellow.

Source: Stephen Frisch/McGraw Hill

All molecules or ions with four electron groups around a central atom adopt the **tetrahedral arrangement** of electron groups. There are three shapes with this arrangement:

1. *Four bonding groups: tetrahedral shape (AX_4).* Methane has a tetrahedral shape, a very common geometry in organic molecules. In Sample Problem 10.1, we drew the Lewis structure for CCl_2F_2 , without regard to relative placement of the four halogen atoms around the carbon atom. Because Lewis structures are flat, it may seem like you can write two different ones for CCl_2F_2 , but they represent the same molecule, as a twist of the wrist reveals (Figure 10.6).

2. *Three bonding groups and one lone pair: trigonal pyramidal shape (AX_3E).* Ammonia (NH_3) is an example of a molecule with a **trigonal pyramidal shape**, a tetrahedron with one vertex “missing.” The lone pair can occupy any of the four corners of the tetrahedron because all of the ideal bond angles are 109.5° . Stronger repulsions by the lone pair make the $H-N-H$ bond angle slightly less than the ideal 109.5° . The lone pair forces the $N-H$ pairs closer to each other, and the bond angle is 107.3° . NF_3 , whose Lewis structure we drew at the beginning of Section 10.1, also has a trigonal pyramidal shape.

Picturing shapes is a great way to visualize a reaction. For instance, when ammonia reacts with an acid, the lone pair on N forms a bond to the H^+ and yields the ammonium ion (NH_4^+), one of many tetrahedral polyatomic ions. As the lone pair becomes a bonding pair, the $H-N-H$ angle expands from 107.3° to 109.5° :

3. *Two bonding groups and two lone pairs: bent (AX_2E_2).* Water is the most important bent molecule with the tetrahedral arrangement. [Note that, in the trigonal planar arrangement, the bent shape has two bonding groups and *one* lone pair (AX_2E), and its ideal bond angle is 120° , not 109.5° .] Repulsions from two lone pairs (which can be placed at any two corners of the tetrahedron) are greater than from one, and the $H-O-H$ bond angle is 104.5° , less than the $H-N-H$ angle in NH_3 :

Thus, for similar molecules within a given electron-group arrangement, electron-electron repulsions cause deviations from ideal bond angles in the following order:

$$\text{Lone pair-lone pair} > \text{lone pair-bonding pair} > \text{bonding pair-bonding pair} \quad (10.2)$$

Molecular Shapes with Five Electron Groups (Trigonal Bipyramidal Arrangement)

All molecules with five or six electron groups have a central atom from Period 3 or higher because only those atoms have *d* orbitals available to expand the valence shell.

Relative Positions of Electron Groups Five mutually repelling electron groups form the **trigonal bipyramidal arrangement**, in which two trigonal pyramids share a common base (Figure 10.7). This is the only case in which *there are two different positions for electron groups and two ideal bond angles*:

- Three **equatorial groups** lie in a trigonal plane that includes the central atom; a 120° bond angle separates the equatorial groups.
- Two **axial groups** lie above and below this plane; a 90° angle separates axial from equatorial groups.

Two factors come into play:

- The greater the bond angle, the weaker the repulsions, so *equatorial-equatorial* (120°) *repulsions are weaker than axial-equatorial* (90°) *repulsions*.
- The stronger repulsions from lone pairs means that, when possible, *lone pairs occupy equatorial positions*.

Shapes for the Trigonal Bipyramidal Arrangement The tendency for lone pairs to occupy equatorial positions, and thus minimize stronger axial-equatorial repulsions, governs three of the four shapes for this arrangement.

1. *Five bonding groups: trigonal bipyramidal shape (AX₅)*. Phosphorus pentachloride (PCl₅) has a trigonal bipyramidal shape. With five identical surrounding atoms, the bond angles are ideal:

2. *Four bonding groups and one lone pair: seesaw shape (AX₄E)*. Sulfur tetrafluoride (SF₄) has the **seesaw shape**; in Figure 10.7, the “seesaw” is tipped on an end. This is the first example of a *lone pair occupying an equatorial position* to minimize repulsions. The lone pair, which can be placed in any of the three equatorial positions, repels all four bonding pairs, reducing the bond angles to 101.5° and 86.8° :

3. *Three bonding groups and two lone pairs: T shape (AX₃E₂)*. Bromine trifluoride (BrF₃), one of many compounds with fluorine bonded to a larger halogen, is **T-shaped**. Since both lone pairs occupy equatorial positions, we see a greater decrease in the axial-equatorial bond angle, bringing it down to 86.2° :

4. *Two bonding groups and three lone pairs: linear shape (AX₂E₃)*. The triiodide ion (I₃⁻), which forms when I₂ dissolves in aqueous I⁻ solution, is linear. With three

equatorial lone pairs and two axial bonding pairs, the three nuclei form a straight line and a 180° X—A—X bond angle:

Molecular Shapes with Six Electron Groups (Octahedral Arrangement)

Six electron groups form the **octahedral arrangement**. An *octahedron* is a polyhedron with eight equilateral triangles for faces and six identical vertices (Figure 10.8). Each of the six groups points to a corner, giving 90° ideal bond angles.

1. *Six bonding groups: octahedral shape (AX_6).* When seesaw-shaped SF_4 reacts with more F_2 , the central S atom expands its valence shell further to form octahedral sulfur hexafluoride (SF_6):

2. *Five bonding groups and one lone pair: square pyramidal shape (AX_5E).* Iodine pentafluoride (IF_5) has a **square pyramidal shape**. Note that it makes no difference where the one lone pair resides because all the ideal bond angles are 90° . The lone pair reduces the bond angles to 81.9° :

3. *Four bonding groups and two lone pairs: square planar shape (AX_4E_2).* Xenon tetrafluoride (XeF_4) has a **square planar shape**. To avoid the stronger lone pair–lone pair repulsions that would result if the two lone pairs were adjacent to each other, they lie *opposite* each other; since each lone pair decreases the bond angles by the same magnitude but in opposite directions, the bond angles remain at 90° :

Figure 10.9 summarizes the molecular shapes we've discussed.

Using VSEPR Theory to Determine Molecular Shape

Let's apply a stepwise method for using VSEPR theory to determine a molecular shape from a molecular formula (Figure 10.10):

Step 1. Write the Lewis structure from the molecular formula (see Figure 10.1) to see the relative placement of atoms and the number of electron groups around the central atom. Since the Lewis structure is two-dimensional, you do not have to be concerned about molecular shape at this point.

Step 2. Assign one of the five electron-group arrangements (see Figure 10.2) by counting *all* electron groups (bonding plus nonbonding) around the central atom.

Step 3. Predict the ideal bond angle from the electron-group arrangement and *the effect of any deviation* caused by lone pairs or double bonds.

Step 4. Draw and name the molecular shape by counting bonding groups and nonbonding groups separately.

The next two sample problems apply these steps.

SAMPLE PROBLEM 10.6

Examining Shapes with Two, Three, or Four Electron Groups

Problem Draw the molecular shapes and predict the bond angles (relative to the ideal angles) of (a) PF_3 and (b) COCl_2 .

Solution (a) For PF_3 :

Step 1. Write the Lewis structure from the formula (see below).

Step 2. Assign the electron-group arrangement: three bonding groups and one lone pair give four electron groups around P and the *tetrahedral arrangement*.

Step 3. Predict the bond angle: the ideal bond angle in a tetrahedron is 109.5° . There is one lone pair, so the actual bond angle will be less than 109.5° .

Step 4. Draw and name the molecular shape: with one lone pair, PF_3 has a *trigonal pyramidal* shape (AX_3E):

(b) For COCl_2 :

Step 1. Write the Lewis structure from the formula (see below).

Step 2. Assign the electron-group arrangement: two single bonds and one double bond give three electron groups around C and the *trigonal planar arrangement*.

Step 3. Predict the bond angles: the ideal bond angle in the trigonal planar arrangement is 120° , but the double bond between C and O will compress the $\text{Cl}-\text{C}-\text{Cl}$ angle to less than 120° .

Step 4. Draw and name the molecular shape: with three electron groups and no lone pairs, COCl_2 has a *trigonal planar* shape (AX_3):

Check We compare the answers with the general information in Figure 10.9.

Comment Be sure the Lewis structure is correct because it determines the other steps. Notice that the electron-group arrangement and the molecular geometry are the same for COCl_2 , since there are no lone pairs on the central C atom; because the central P atom in PF_3 has a lone pair, the electron-group arrangement and molecular geometry are different for this molecule.

FOLLOW-UP PROBLEMS

10.6A Draw the molecular shapes and predict the bond angles (relative to the ideal angles) of (a) CS_2 ; (b) PbCl_2 (Pb is electron deficient); (c) CBr_4 ; (d) SF_2 .

10.6B Name the electron-group arrangements, draw and name the molecular shapes, and predict the bond angles (relative to the ideal angles) of (a) BrO_2^- ; (b) AsH_3 ; (c) N_3^- ; (d) SeO_3 .

SOME SIMILAR PROBLEMS 10.34–10.37

SAMPLE PROBLEM 10.7 | Examining Shapes with Five or Six Electron Groups

Problem Draw the molecular shapes and predict the bond angles (relative to the ideal angles) of (a) SbF_5 and (b) BrF_5 .

Plan We proceed as in Sample Problem 10.6, being sure to minimize the number of axial-equatorial repulsions.

Solution (a) For SbF_5 :

Step 1. Lewis structure (*see below*).

Step 2. Electron-group arrangement: with five electron groups (five bonding pairs), this molecule has the *trigonal bipyramidal* arrangement.

Step 3. Bond angles: all the groups and surrounding atoms are identical, so the bond angles are ideal: 120° between equatorial groups and 90° between axial and equatorial groups.

Step 4. Molecular shape: five electron groups and no lone pairs give the *trigonal bipyramidal* shape (AX_5):

(b) For BrF_5 :

Step 1. Lewis structure (*see below*).

Step 2. Electron-group arrangement: six electron groups (five bonding pairs and one lone pair) give the *octahedral* arrangement.

Step 3. Bond angles: the lone pair will make all bond angles less than the ideal 90° .

Step 4. Molecular shape: with one lone pair, BrF_5 has the *square pyramidal* shape (AX_5E):

Check We compare our answers with Figure 10.9.

FOLLOW-UP PROBLEMS

10.7A Draw the molecular shapes and predict the bond angles (relative to the ideal angles) of (a) ICl_2^- ; (b) ClF_3 ; (c) SOF_4 .

10.7B Draw the molecular shapes and predict the bond angles (relative to the ideal angles) of (a) BrF_4^- ; (b) ClF_4^+ ; (c) PCl_6^- .

Molecular Shapes with More Than One Central Atom

The shapes of molecules with more than one central atom are composites of the shapes around each of the atoms. Here are two examples:

1. Ethane (CH_3CH_3 ; molecular formula C_2H_6) is a component of natural gas. With four bonding groups and no lone pairs around the two central carbons, ethane is shaped like two overlapping tetrahedra (Figure 10.11A).
2. Ethanol ($\text{CH}_3\text{CH}_2\text{OH}$; molecular formula $\text{C}_2\text{H}_6\text{O}$), the intoxicating substance in beer, wine, and whiskey, has three central atoms (Figure 10.11B). The $-\text{CH}_3$ group is tetrahedrally shaped, and the $-\text{CH}_2-$ group has four bonding groups around its

Figure 10.11 The tetrahedral shapes around the central atoms and the overall shapes of ethane (A) and ethanol (B).

central C atom, so it is also tetrahedrally shaped. The O atom has two bonding groups and two lone pairs around it, so the —OH group has a bent shape (AX_2E_2).

SAMPLE PROBLEM 10.8

Predicting Molecular Shapes with More Than One Central Atom

Problem Determine the shape around each central atom in acetone, $(CH_3)_2CO$.

Plan There are three central C atoms, two of which are in CH_3 — groups. We determine the shape around one central atom at a time.

Solution *Step 1.* Lewis structure (see below).

Step 2. Electron-group arrangement: each CH_3 — group has four electron groups around its central C, so its electron-group arrangement is *tetrahedral*. The third C atom has three electron groups around it, so it has the *trigonal planar* arrangement.

Step 3. Bond angles: the $H—C—H$ angle in CH_3 — should be near the ideal 109.5° . The $C=O$ double bond will compress the $C—C—C$ angle to less than the ideal 120° .

Step 4. Shapes around central atoms: with four electron groups and no lone pairs, the shape around C in each CH_3 — is *tetrahedral* (AX_4). With three electron groups and no lone pairs, the shape around the middle C is *trigonal planar* (AX_3):

FOLLOW-UP PROBLEMS

10.8A Determine the shape around each central atom and predict any deviations from ideal bond angles in the following: (a) H_2SO_4 ; (b) propyne (C_3H_4 ; there is one $C\equiv C$ bond); (c) S_2F_2 .

10.8B Determine the shape around each central atom and predict any deviations from ideal bond angles in the following: (a) CH_3NH_2 ; (b) C_2Cl_4 ; (c) Cl_2O_7 ($O_3ClOClO_3$).

SOME SIMILAR PROBLEMS 10.42–10.45

Summary of Section 10.2

- › VSEPR theory proposes that each electron group (single bond, multiple bond, lone pair, or lone electron) around a central atom remains as far from the others as possible.
- › Five electron-group arrangements are possible when two, three, four, five, or six electron groups surround a central atom. Each arrangement is associated with one or more molecular shapes, depending on the numbers of bonding and lone pairs.
- › Ideal bond angles are based on the regular geometric arrangements. Deviations from them occur when surrounding atoms and/or electron groups are not identical.
- › Lone pairs and double bonds exert stronger repulsions on other electron groups than single bonds do.
- › Shapes of larger molecules are composites of the shapes around each central atom.

10.3 MOLECULAR SHAPE AND MOLECULAR POLARITY

Knowing the shape of its molecules is key to understanding the physical and chemical behavior of a substance. One of the most far-reaching effects of molecular shape is molecular polarity, which can influence melting and boiling points, solubility, reactivity, and even biological function.

Here are some key points about the polarity of bonds versus the polarity of a molecule:

- Two atoms with different electronegativity values share electrons unequally and the covalent bond is polar (Chapter 9).
- Diatomic molecules contain only one bond, so the bond polarity and the polarity of the molecule are the same. F_2 contains only one nonpolar bond (the electrons in the single bond are shared equally between the two F atoms), so F_2 is a nonpolar molecule. The only bond in HF is polar, so the molecule is polar.
- In larger molecules, with more than one bond, *both shape and bond polarity determine molecular polarity*, an uneven distribution of charge over the whole molecule or a large portion of it.
- Dipole moment (μ)** is a measure of molecular polarity, given in the unit called a *debye (D)*,* which is derived from SI units of charge (coulomb, C) and length (m):
 $1 \text{ D} = 3.34 \times 10^{-30} \text{ C} \cdot \text{m}$.

Polar molecules have a partially negatively charged end (δ^-) and a partially positively charged end (δ^+); they become oriented in an electric field with their partially charged ends pointing toward the oppositely charged plate (Figure 10.12).

Bond Polarity, Bond Angle, and Dipole Moment

The presence of polar bonds does not *always* result in a polar molecule; we must also consider shape and the atoms surrounding the central atom. Here are three cases:

1. CO_2 : *polar bonds, nonpolar molecule*. In carbon dioxide, the electronegativity difference between C (EN = 2.5) and O (EN = 3.5) makes each C=O bond polar, with electron density pulled from C toward O. But CO_2 is linear, so the bonds point 180° from each other. Since the two bonds have polarities that are equal in magnitude but opposite in direction, their polarities cancel, resulting in *no net dipole moment* for the molecule ($\mu = 0 \text{ D}$), just as two numbers of equal magnitude but opposite sign (for example, +1 and -1) add to 0. The electron density model shows regions of high negative charge (*red*) distributed equally on either side of the central region of high positive charge (*blue*):

In general, AX_mE_n molecules that have polar bonds will exhibit no net dipole moment (nonpolar) if all surrounding atoms are the same and are arranged symmetrically around the central atom, an arrangement that occurs when all corners of the electron-group arrangement are occupied by atoms and there are no lone pairs on the central atom.

2. H_2O : *polar bonds, polar molecule*. Water also has two polar bonds, but it is polar ($\mu = 1.85 \text{ D}$). In each O—H bond, electron density is pulled from H (EN = 2.1) toward O (EN = 3.5). Bond polarities do *not* cancel because the molecule is bent (see also

Electric field off: HF molecules are oriented randomly.

Electric field on: HF molecules are oriented with their partially charged ends toward the oppositely charged plates.

Figure 10.12 The orientation of polar molecules in an electric field.

*The unit is named for the Dutch-American scientist Peter Debye (1884–1966), who won the Nobel Prize in chemistry in 1936 for contributions to the fields of molecular structure and solution behavior.

Figure 4.4). The bond polarities are partially reinforced, making the O end partially negative and the other end (the region between the H atoms) partially positive:

In general, AX_mE_n molecules with polar bonds will have a net dipole moment (polar) when at least one corner of the electron-group arrangement is occupied by a lone pair. Exceptions to this are the linear (AX_2E_3) and square planar (AX_4E_2) molecular geometries.

3. *Same shapes, different polarities.* When different molecules have the same shape, the identities of the surrounding atoms affect polarity. Carbon tetrachloride (CCl_4) and chloroform ($CHCl_3$) are tetrahedral molecules with very different polarities. In CCl_4 , all the surrounding atoms are Cl atoms. Each C—Cl bond is equally polar ($\Delta EN = 0.5$), but the molecule is nonpolar ($\mu = 0$ D) because the bond polarities cancel each other. In $CHCl_3$, an H replaces one Cl. The polarity of the H—C bond differs in magnitude ($\Delta EN = 0.4$) and direction from that of the three C—Cl bonds; thus, it disrupts the balance and gives chloroform a significant dipole moment ($\mu = 1.01$ D):

SAMPLE PROBLEM 10.9 Predicting the Polarity of Molecules

Problem For each of the following, use the molecular shape and EN values and trends (Figure 9.20) to predict the direction of bond and molecular polarity, if present: (a) ammonia, NH_3 ; (b) boron trifluoride, BF_3 ; (c) carbonyl sulfide, COS (atom sequence SCO).

Plan We draw and name the molecular shape and point a polar arrow toward the atom with higher EN in each bond. If the bond polarities balance one another, the molecule is nonpolar; if they reinforce each other, we show the direction of the molecular polarity.

Solution (a) For NH_3 : the molecular shape is trigonal pyramidal. N ($EN = 3.0$) is more electronegative than H ($EN = 2.1$), so the bond polarities point toward N and partially reinforce each other; thus, the molecular polarity points toward N:

Therefore, ammonia is polar.

(b) For BF_3 : the molecular shape is trigonal planar. F ($EN = 4.0$) is farther to the right in Period 2 than B ($EN = 2.0$), so it is more electronegative; thus, each bond polarity points toward F. However, the bond angle is 120° , so the three bond polarities balance each other, and BF_3 has no molecular polarity:

Therefore, boron trifluoride is nonpolar.

Student Hot Spot

Student data indicate that you may struggle with determining molecular polarity. Access the eBook to view an additional Learning Resource video on this topic.

(c) For COS: the molecular shape is linear. C and S have the same EN value; thus, $\Delta\text{EN} = 0$ and the C=S bond is nonpolar, but the C=O bond is quite polar ($\Delta\text{EN} = 1.0$), so there is a net molecular polarity toward the O:

Therefore, carbonyl sulfide is polar.

Check The electron density models confirm our conclusions. Note that, in (b), the negative (red) regions surround the central B (blue) symmetrically.

FOLLOW-UP PROBLEMS

10.9A Show the bond polarities and molecular polarity, if any, for each of the following: (a) dichloromethane (CH_2Cl_2); (b) iodine oxide pentafluoride (IOF_5); (c) iodine pentafluoride (IF_5).

10.9B Show the bond polarities and molecular polarity, if any, for each of the following: (a) xenon tetrafluoride (XeF_4); (b) chlorine trifluoride (ClF_3); (c) sulfur monoxide tetrafluoride (SOF_4).

SOME SIMILAR PROBLEMS 10.55–10.58

The Effect of Molecular Polarity on Behavior

Earlier we mentioned that molecular polarity influences physical behavior. Let's see how a molecular property like dipole moment affects a macroscopic property like boiling point.

Consider the two dichloroethylenes shown below. They have the *same* molecular formula ($\text{C}_2\text{H}_2\text{Cl}_2$) but *different* physical and chemical properties. Both molecules are planar, with a trigonal planar shape around each C atom. The *trans* compound with the two Cl atoms on opposite sides of the double bond is nonpolar ($\mu = 0 \text{ D}$) because the polar C—Cl bonds balance each other. The *cis* compound with the Cl atoms on the same side of the double bond is polar ($\mu = 1.90 \text{ D}$) because the bond polarities partially reinforce each other, with the molecular polarity pointing between the Cl atoms.

A liquid boils when molecules in the liquid overcome the weak attractive forces *between* them. Because of their polarity, the *cis* molecules, with their partially positive and partially negative charged ends, attract each other more strongly than the *trans* molecules do. Since more energy is needed to overcome the stronger attractions, we expect the *cis* compound to have a higher boiling point: *cis*-1,2-dichloroethylene boils 13°C higher than *trans*-1,2-dichloroethylene.

Thus, molecular polarity affects the physical properties and behavior of substances and, as discussed in the upcoming Chemical Connections essay, molecular shape and polarity have biological effects as well.

Many complex processes begin when a molecular “key” fits into a molecular “lock” with a complementary shape. Typically, the key is a small molecule circulating in cellular or other bodily fluid, and the lock, the *biological receptor*, is a large molecule often embedded in a membrane. The *receptor site* is a small region of the receptor with a shape that matches the molecular key. Thousands of molecules per second collide with the receptor site, but, when one with the correct shape does, the receptor site “grabs” it through intermolecular attractions, and the biological response begins.

Molecular Shape and the Senses of Smell and Taste

Molecular shapes fitting together is crucial to the senses of smell and taste:

- **Smell.** To have an odor, a substance must be a gas, or a liquid or solid that is easily vaporized, and must be at least slightly soluble in the aqueous film of the nasal passages. And the odorous molecule, or a portion of it, must fit into one of the receptor sites on nerve endings in this area. When this happens, nerve impulses travel to the brain, which interprets them as a specific odor. The 2004 Nobel Prize in physiology or medicine was given to Richard Axel and Linda B. Buck for showing that olfaction involves about 1000 different receptors and that molecules fitting various combinations of them produce the more than 10,000 odors humans can distinguish. Thus, odor depends on molecular shape, an idea that is being actively researched in the food, cosmetics, and insecticide industries.
- **Taste.** Taste buds on our tongues are composed of taste cells; taste receptor sites are embedded in the cell membranes of these taste cells. Flavor ingredients fit into certain receptors, triggering a process that sends signals to the brain. For example,

sugars and artificial sweeteners fit into the taste bud receptors that signal sweetness. Notice the similarity in molecular structure and shape of sugar (sucrose) and the artificial sweetener sucralose shown in Figure B10.1; it is not surprising that both molecules fit into the same taste cell receptors.

Biological Significance of Molecular Shape

Countless other examples show that no chemical property is more crucial to living systems than molecular shape. Here are just a few of the many biochemical processes controlled by one molecule fitting into a receptor site on another:

- Enzymes are proteins that bind cellular reactants and speed their reaction. When a reactant molecule fits into an active site on the enzyme, the reaction begins.
- Nerve impulses are transmitted when small molecules released from one nerve fit into receptors on the next. Mind-altering drugs act by chemically mimicking the molecular fit at such nerve receptors in the brain.
- One type of immune response is triggered when a molecule on a bacterial surface binds to the receptors on “killer” cells in the bloodstream.
- Hormones regulate processes by fitting into and activating specific receptors on target tissues and organs.
- Genes function when certain nucleic acid molecules fit into specific regions of others.

Figure B10.1 Molecular structure of sucrose and sucralose. In sucralose, three O—H groups (red and white spheres) have been replaced with Cl atoms (green spheres).

Problems

B10.1 As you’ll learn in Chapter 11, groups joined by a single bond rotate freely around the bond, but those joined by double bonds don’t. Peptide bonds make up a major portion of protein chains. Determine the molecular shapes around the central C and N atoms in the two resonance forms of the peptide bond:

B10.2 Lewis structures of mescaline, a hallucinogenic compound in peyote cactus, and dopamine, a neurotransmitter in the

mammalian brain, are shown below. Suggest a reason for mescaline’s ability to disrupt nerve impulses.

› Summary of Section 10.3

- › Bond polarity and molecular shape determine molecular polarity, which is measured as a dipole moment.
- › A molecule with polar bonds is not necessarily a polar molecule. When bond polarities cancel each other, the molecule is nonpolar; when they reinforce each other, the molecule is polar.
- › Molecular shape and polarity can affect physical properties, such as boiling point, and they play a central role in biological function.

CHAPTER REVIEW GUIDE

Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

Understand These Concepts

1. How Lewis structures depict the atoms, bonding pairs, and lone electron pairs in a molecule or polyatomic ion (§10.1)
2. How resonance and electron delocalization explain bond properties in many compounds with double bonds adjacent to single bonds (§10.1)
3. The meaning of formal charge and how it is used to select the more important resonance structure; the difference between formal charge and oxidation number (§10.1)
4. The octet rule and its three major exceptions—molecules with a central atom that has an electron deficiency, an odd number of electrons, or an expanded valence shell (§10.1)
5. How electron-group repulsions lead to molecular shapes (§10.2)
6. The five electron-group arrangements and their associated molecular shapes (§10.2)

7. Why double bonds and lone pairs cause deviations from ideal bond angles (§10.2)
8. How bond polarities and molecular shape combine to give a molecule polarity (§10.3)

Master These Skills

1. Using a stepwise method for writing a Lewis structure from a molecular formula (SPs 10.1–10.3, 10.5)
2. Writing resonance structures for molecules and ions (SP 10.4)
3. Calculating the formal charge of any atom in a molecule or an ion (SPs 10.4, 10.5)
4. Predicting molecular shapes from Lewis structures (SPs 10.6–10.8)
5. Using molecular shape and electronegativity values to predict the polarity of a molecule (SP 10.9)

Key Terms

Page numbers appear in parentheses.

axial group (417)	formal charge (406)	resonance hybrid (405)	trigonal planar
bent (415)	free radical (409)	resonance structure (404)	arrangement (414)
bond angle (414)	Lewis structure (Lewis	seesaw shape (417)	trigonal pyramidal shape (416)
dipole moment (μ) (423)	formula) (399)	square planar shape (418)	valence-shell electron-pair
electron deficient (408)	linear arrangement (414)	square pyramidal shape (418)	repulsion (VSEPR)
electron-pair	linear shape (414)	T-shaped (417)	theory (413)
delocalization (405)	molecular polarity (423)	tetrahedral arrangement (416)	
equatorial group (417)	molecular shape (413)	trigonal bipyramidal	
expanded valence shell (410)	octahedral arrangement (418)	arrangement (417)	

Key Equations and Relationships

Page numbers appear in parentheses.

10.1 Calculating the formal charge on an atom (406):

Formal charge of atom

= no. of valence e^-

– (no. of unshared valence $e^- + \frac{1}{2}$ no. of shared valence e^-)

10.2 Ranking the effect of electron-pair repulsions on bond angle (416):

Lone pair–lone pair > lone pair–bonding pair >

bonding pair–bonding pair

CHAPTER PRACTICE TEST

The answers to the Practice Test problems are shown below and the full solutions can be found in the e-book.

1. There are three H—O—C bond angles in the compound epinephrine. They are each

(a) 180° (b) 120° (c) $<120^\circ$ (d) 109.5° (e) $<109.5^\circ$ (f) 90°

2. In which of the following does the central atom have exactly one unshared pair of electrons?

(a) XeO_4 (b) BrO_4^- (c) NH_2^- (d) AsF_3 (e) SO_3

3. Which of the following has a linear molecular shape?

(a) BrO_2^- (b) HNO (N is the central atom) (c) ClF_2^-
(d) OF_2 (e) NO_2^-

4. What is the molecular shape of XeF_3^+ ?

(a) trigonal planar (b) T-shaped (c) trigonal pyramidal
(d) bent (e) see-saw

5. In which of the following does the central atom have an expanded octet?

(a) ICl_4^- (b) NO_3^- (c) H_2CO (C is the central atom)
(d) SiCl_4 (e) AsF_3

6. Which of the following statements about SiCl_4 is correct?

(a) SiCl_4 has nonpolar bonds and is a nonpolar molecule.
(b) SiCl_4 has polar bonds and is a nonpolar molecule.
(c) SiCl_4 has nonpolar bonds and is a polar molecule.
(d) SiCl_4 has polar bonds and is a polar molecule.

7. For which of the following can resonance structures be drawn?

(a) NO_2^+ (b) OF_2 (c) H_2CO (d) CCl_4 (e) NH_4^+

8. From the following resonance structures, select the one with the lowest formal charges:

(a) Structure A (b) Structure B (c) Structure C
(d) All 3 have the same formal charges

9. Which of the following molecules is polar?

(a) XeO_4 (b) SO_3 (c) TeF_4 (d) CCl_4 (e) XeF_4

10. Which **two** of the following statements correctly describe XeF_2 ?

(a) XeF_2 has a bent molecular shape.
(b) Xe is surrounded by a total of 5 electron pairs.
(c) XeF_2 has bond angles of 120° and 90° .
(d) Xe is surrounded by 3 unshared pairs of electrons.
(e) XeF_2 has a trigonal bipyramidal molecular shape.
(f) XeF_2 has a dipole moment.

Answers: 1. e; 2. d; 3. c; 4. b; 5. a; 6. b; 7. a; 8. c; 9. c; 10. b, d

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

10.1A (a) 8 valence e^- — ($4e^-$ in 2 bonds) — $4e^-$ to complete the octet of S.

(b) 32 valence e^- — ($8e^-$ in 4 bonds) — $24e^-$ to complete the octets of the Cl atoms.

(c) Place S in the center, since it has the lowest electronegativity value. 26 valence e^- — ($6e^-$ in 3 bonds) — $20e^-$ to complete the octets of all atoms.

10.1B (a) 20 valence e^- — ($4e^-$ in 2 bonds) — $16e^-$ to complete the octets of all atoms.

(b) Place C in the center, since it has a lower electronegativity than Br, and H cannot be a central atom. 20 valence e^- — ($8e^-$ in 4 bonds) — $12e^-$ to complete the octets of the Br atoms.

(c) 20 valence e^- — ($4e^-$ in 2 bonds) — $16e^-$ to complete the octets of all atoms.

10.2A (a) H atoms can have only one bond; O should have two bonds and N should have three bonds, so the atoms are arranged as shown. 14 valence e^- — ($8e^-$ in 4 bonds) — $6e^-$ to complete the octets of N and O.

(b) H atoms can have only one bond; O should have two bonds and C should have four bonds; there are no O—H bonds, so the atoms are arranged as shown. 20 valence e^- — ($16e^-$ in 8 bonds) — $4e^-$ to complete the octet of O.

10.2B (a) H atoms can have only one bond, so the atoms are arranged as shown. 14 valence e^- — ($10e^-$ in 5 bonds) — $4e^-$ to complete the octets of the N atoms.

(b) H atoms can have only one bond; N should have three bonds and C should have four bonds, so the atoms are arranged as shown. 14 valence e^- – (12 e^- in 6 bonds) – 2 e^- to complete the octet of the N atom.

10.3A (a) Using the 10 valence e^- in CO gives a Lewis structure in which C does not have an octet; two lone pairs on O are changed to bonding pairs:

(b) Using the 12 valence e^- in O_2 gives a Lewis structure in which one O atom does not have an octet; one lone pair on the O atom with an octet is changed to a bonding pair:

(c) Using the 16 valence e^- in CO_2 gives a Lewis structure in which C does not have an octet; one lone pair on each O atom is changed to a bonding pair:

10.3B (a) Using the 10 valence e^- in NO^+ gives a Lewis structure in which an atom does not have an octet; two lone pairs are changed to bonding pairs:

(b) Using the 12 valence e^- in H_2CO gives a Lewis structure in which C does not have an octet; one lone pair on O is changed to a bonding pair:

(c) Using the 12 valence e^- in N_2H_2 gives a Lewis structure in which one N atom does not have an octet; one lone pair on the other N atom is changed to a bonding pair:

10.4A After distributing the 24 valence e^- , the N atom does not have an octet. A lone pair on either O atom is changed to a bonding pair to give N an octet.

Formal charge of atom = no. of valence e^- – (no. of unshared valence e^- + $\frac{1}{2}$ no. of shared valence e^-)

N $[5 - 0 - \frac{1}{2}(8)] = +1$; C $[4 - 0 - \frac{1}{2}(8)] = 0$; H $[1 - 0 - \frac{1}{2}(2)] = 0$;
O (single-bonded) $[6 - 6 - \frac{1}{2}(2)] = -1$;
O (double-bonded) $[6 - 4 - \frac{1}{2}(4)] = 0$

10.4B After distributing the 16 valence e^- , C has only two bonds (four e^-); lone pairs on either S, N, or both are changed to bonding pairs. Formal charges:

Structure I is the most important resonance structure; the formal charges are lower than those in structure III, and the negative formal charge is on the more electronegative N atom, while the negative formal charge in structure II is on the less electronegative S atom.

10.5A (a) Change a lone pair on O to a bonding pair to minimize formal charges.

(b) Change a lone pair on each O to a bonding pair to minimize formal charges. Note the unpaired electron on the Cl atom.

(c) 36 valence e^- – (8 e^- in 4 bonds) – (24 e^- to complete the octets of the Br atoms) – 4 e^- on the central I.

10.5B (a) Be has only four electrons surrounding it, so the molecule is electron deficient:

(b) 22 valence e^- – (4 e^- in 2 bonds) – (16 e^- to complete the octets of the I atoms) – 2 e^- on the central I.

(c) Change a lone pair on each O to a bonding pair to minimize formal charges.

10.6A (a) Two electron groups: linear electron-group arrangement. No lone pairs: linear shape and 180° bond angle.

(b) Three electron groups: trigonal planar electron-group arrangement. One lone pair: bent and bond angle < 120°.

(c) There are four electron groups with a tetrahedral electron-group arrangement. Since there are no lone pairs, the molecular shape is tetrahedral with bond angles of 109.5°.

(d) Four electron groups: tetrahedral electron-group arrangement. Two lone pairs: bent and bond angle < 109.5°.

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS (continued)

10.6B (a) Four electron groups: tetrahedral electron-group arrangement. Two lone pairs: bent and bond angle $<109.5^\circ$.

(b) Four electron groups: tetrahedral electron-group arrangement. One lone pair: trigonal pyramidal shape and bond angle $<109.5^\circ$.

(c) Two electron groups: linear electron-group arrangement. Linear shape and 180° bond angle.

(d) Three electron groups: trigonal planar electron-group arrangement. No lone pairs: trigonal planar shape and 120° bond angles.

10.7A (a) Five electron groups: trigonal bipyramidal electron-group arrangement. Three lone pairs: linear shape and 180° bond angle. The three lone pairs occupy equatorial positions to minimize repulsions.

(b) Five electron groups: trigonal bipyramidal electron-group arrangement. Two lone pairs: T-shaped and bond angles $<90^\circ$. The two lone pairs occupy equatorial positions to minimize repulsions.

(c) Five electron groups: trigonal bipyramidal electron-group arrangement. No lone pairs: trigonal bipyramidal shape. The double bond reduces the bond angles: $F_{eq}-S-F_{eq}$ angle $<120^\circ$; $F_{ax}-S-F_{eq}$ angle $<90^\circ$.

10.7B (a) Six electron groups: octahedral electron-group arrangement. Two lone pairs: square planar shape and bond angles of 90° .

(b) Five electron groups: trigonal bipyramidal electron-group arrangement. One lone pair: seesaw shape. The lone pair reduces the bond angles: $F_{eq}-Cl-F_{eq}$ angle $<120^\circ$; $F_{ax}-Cl-F_{eq}$ angle $<90^\circ$. The lone pair occupies an equatorial position to minimize repulsions.

(c) Six electron groups: octahedral electron-group arrangement. No lone pairs: octahedral shape and bond angles of 90° .

10.8A (a) S: four electron groups; tetrahedral shape; double bonds compress the $O-S-O$ angle to $<109.5^\circ$. O: four electron groups, two of which are lone pairs; bent; the lone pairs compress the $H-O-S$ angle to $<109.5^\circ$.

(b) C (in CH_3): four electron groups; tetrahedral shape; bond angles $\sim 109.5^\circ$. C (in triple bond): two electron groups; linear shape and bond angle = 180° .

(c) S: four electron groups, two of which are lone pairs; bent; $F-S-S$ bond angle $<109.5^\circ$.

10.8B (a) C: four electron groups; tetrahedral shape; bond angles = 109.5° . N: four electron groups, one of which is a lone pair; trigonal pyramidal shape; bond angle $<109.5^\circ$.

(b) C: three electron groups; trigonal planar shape; the double bond compresses each Cl—C—Cl angle to $<120^\circ$.

(c) Cl: four electron groups; tetrahedral shape; bond angles $\sim 109.5^\circ$. O (central): four electron groups, two of which are lone pairs; bent; Cl—O—Cl bond angle $<109.5^\circ$.

10.9A (a) The C—H and C—Cl polar bonds reinforce each other, with the molecular polarity pointing between the Cl atoms.

(b) Four of the polar I—F bonds balance each other, but the fifth I—F bond is not balanced by the polar O—I bond. Since the I—F bond is more polar ($\Delta EN = 1.5$) than the O—I bond ($\Delta EN = 1.0$), the molecular polarity points toward the F atom.

(c) Four of the I—F bonds balance each other, but the fifth I—F bond is not balanced. The molecular polarity points toward the F atom.

10.9B (a) The four polar Xe—F bonds balance each other: nonpolar molecule.

(b) Two of the Cl—F bonds balance each other, but the third Cl—F bond is not balanced. The molecular polarity points toward the F atom.

(c) The two axial S—F bonds balance each other, but the two equatorial S—F bonds ($\Delta EN = 1.5$) are not balanced by the double bond between S and O ($\Delta EN = 1.0$). Since the S—F bonds are more polar, the molecular polarity points between the F atoms.

PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

Depicting Molecules and Ions with Lewis Structures (Sample Problems 10.1 to 10.5)

Concept Review Questions

10.1 Which of these atoms *cannot* serve as a central atom in a Lewis structure: (a) O; (b) He; (c) F; (d) H; (e) P? Explain.

10.2 When is a resonance hybrid needed to adequately depict the bonding in a molecule? Using NO_2 as an example, explain how a resonance hybrid is consistent with the actual bond length, bond strength, and bond order.

10.3 In which of these structures does X obey the octet rule?

10.4 What is required for an atom to expand its valence shell? Which of the following atoms can expand its valence shell: F, S, H, Al, Se, Cl?

Skill-Building Exercises (grouped in similar pairs)

10.5 Draw a Lewis structure for (a) SiF_4 ; (b) SeCl_2 ; (c) COF_2 (C is the central atom).

10.6 Draw a Lewis structure for (a) PH_4^+ ; (b) C_2F_4 ; (c) SbH_3 .

10.7 Draw a Lewis structure for (a) PF_3 ; (b) H_2CO_3 (both H atoms are attached to O atoms); (c) CS_2 .

10.8 Draw a Lewis structure for (a) CH_4S ; (b) S_2Cl_2 ; (c) CHCl_3 .

10.9 Draw Lewis structures of all the important resonance forms of (a) NO_2^+ ; (b) NO_2F (N is central).

10.10 Draw Lewis structures of all the important resonance forms of (a) HNO_3 (atom sequence: HONO_2); (b) HAsO_4^{2-} (atom sequence: HOAsO_3^{2-}).

10.11 Draw Lewis structures of all the important resonance forms of (a) N_3^- ; (b) NO_2^- .

10.12 Draw Lewis structures of all the important resonance forms of (a) HCO_2^- (H is attached to C); (b) HBrO_4 (HOBrO_3).

10.13 Draw the Lewis structure with lowest formal charges, and determine the charge of each atom in (a) IF_5 ; (b) AlH_4^- .

10.14 Draw the Lewis structure with lowest formal charges, and determine the charge of each atom in (a) OCS ; (b) NO .

10.15 Draw the Lewis structure with lowest formal charges, and determine the charge of each atom in (a) CN^- ; (b) ClO^- .

10.16 Draw the Lewis structure with lowest formal charges, and determine the charge of each atom in (a) ClF_2^+ ; (b) ClNO .

10.17 Draw a Lewis structure for a resonance form of each ion with the lowest possible formal charges, show the charges, and give oxidation numbers of the atoms: (a) BrO_3^- ; (b) SO_3^{2-} .

10.18 Draw a Lewis structure for a resonance form of each ion with the lowest possible formal charges, show the charges, and give oxidation numbers of the atoms: (a) AsO_4^{3-} ; (b) ClO_2^- .

10.19 These species do not obey the octet rule. Draw a Lewis structure for each, and state the type of octet-rule exception:

(a) BH_3 (b) AsF_4^- (c) SeCl_4

10.20 These species do not obey the octet rule. Draw a Lewis structure for each, and state the type of octet-rule exception:

(a) PF_6^- (b) ClO_3 (c) H_3PO_3 (one P—H bond)

10.21 These species do not obey the octet rule. Draw a Lewis structure for each, and state the type of octet-rule exception:

(a) BrF_3 (b) ICl_2^- (c) BeF_2

10.22 These species do not obey the octet rule. Draw a Lewis structure for each, and state the type of octet-rule exception:

(a) O_3^- (b) XeF_2 (c) SbF_4^-

Problems in Context

10.23 Molten beryllium chloride reacts with chloride ion from molten NaCl to form the BeCl_4^{2-} ion, in which the Be atom attains an octet. Show the net ionic reaction with Lewis structures.

10.24 Despite many attempts, the perbromate ion (BrO_4^-) was not prepared in the laboratory until about 1970. (In fact, articles were published explaining theoretically why it could never be prepared!) Draw a Lewis structure for BrO_4^- in which all atoms have lowest formal charges.

10.25 Cryolite (Na_3AlF_6) is an indispensable component in the electrochemical production of aluminum. Draw a Lewis structure for the AlF_6^{3-} ion.

10.26 Phosgene is a colorless, highly toxic gas that was employed against troops in World War I and is used today as a key reactant in organic syntheses. From the following resonance structures, select the one with the lowest formal charges:

Valence-Shell Electron-Pair Repulsion (VSEPR) Theory

(Sample Problems 10.6 to 10.8)

Concept Review Questions

10.27 If you know the formula of a molecule or an ion, what is the first step in predicting its shape?

10.28 In what situation is the name of the molecular shape the same as the name of the electron-group arrangement?

10.29 Which of the following numbers of electron groups can give rise to a bent molecule: two, three, four, five, six? Draw an example for each case, showing the shape classification (AX_mE_n) and the ideal bond angle.

10.30 Name all the molecular shapes that have a tetrahedral electron-group arrangement.

10.31 Consider the following molecular shapes. (a) Which has the most electron pairs (both bonding and lone pairs) around the central atom? (b) Which has the most lone pairs around the central atom? (c) Do any have only bonding pairs around the central atom?

10.32 Use wedge-bond perspective drawings (if necessary) to sketch the atom positions in a general molecule of formula (not shape class) AX_n that has each of the following shapes:

(a) bent (b) trigonal planar (c) trigonal bipyramidal
(d) T-shaped (e) trigonal pyramidal (f) square pyramidal

10.33 What would you expect to be the electron-group arrangement around atom A in each of the following cases? For each arrangement, give the ideal bond angle and the direction of any expected deviation:

Skill-Building Exercises (grouped in similar pairs)

10.34 Determine the electron-group arrangement, molecular shape, and ideal bond angle(s) for each of the following:

(a) O_3 (b) H_3O^+ (c) NF_3

10.35 Determine the electron-group arrangement, molecular shape, and ideal bond angle(s) for each of the following:

(a) SO_4^{2-} (b) NO_2^- (c) PH_3

10.36 Determine the electron-group arrangement, molecular shape, and ideal bond angle(s) for each of the following:

(a) CO_3^{2-} (b) SO_2 (c) CF_4

10.37 Determine the electron-group arrangement, molecular shape, and ideal bond angle(s) for each of the following:

(a) SO_3 (b) N_2O (N is central) (c) CH_2Cl_2

10.38 Name the shape and give the AX_mE_n classification and ideal bond angle(s) for each of the following general molecules:

10.39 Name the shape and give the AX_mE_n classification and ideal bond angle(s) for each of the following general molecules:

10.40 Determine the shape, ideal bond angle(s), and direction of any deviation from those angles for each of the following:

- (a) ClO_2^- (b) PF_5 (c) SeF_4 (d) KrF_2

10.41 Determine the shape, ideal bond angle(s), and direction of any deviation from those angles for each of the following:

- (a) ClO_3^- (b) IF_4^- (c) SeOF_2 (d) TeF_5^-

10.42 Determine the shape around each central atom in each molecule, and explain any deviation from ideal bond angles:

- (a) CH_3OH (b) N_2O_4 (atom sequence: O_2NNO_2)

10.43 Determine the shape around each central atom in each molecule, and explain any deviation from ideal bond angles:

- (a) H_3PO_4 (no H—P bond) (b) $\text{CH}_3\text{—O—CH}_2\text{CH}_3$

10.44 Determine the shape around each central atom in each molecule, and explain any deviation from ideal bond angles:

- (a) CH_3COOH (b) H_2O_2

10.45 Determine the shape around each central atom in each molecule, and explain any deviation from ideal bond angles:

- (a) H_2SO_3 (no H—S bond) (b) N_2O_3 (atom sequence: ONNO_2)

10.46 Arrange the following AF_n species in order of *increasing* F—A—F bond angles: BF_3 , BeF_2 , CF_4 , NF_3 , OF_2 .

10.47 Arrange the following ACl_n species in order of *decreasing* Cl—A—Cl bond angles: SCl_2 , OCl_2 , PCl_3 , SiCl_4 , SiCl_6^{2-} .

10.48 State an ideal value for each of the bond angles in each molecule, and note where you expect deviations:

10.49 State an ideal value for each of the bond angles in each molecule, and note where you expect deviations:

Problems in Context

10.50 Because both tin and carbon are members of Group 14, they form structurally similar compounds. But tin exhibits a greater variety of structures because it forms several ionic species. Predict the shapes and ideal bond angles, including any deviations:

- (a) $\text{Sn}(\text{CH}_3)_2$ (b) SnCl_3^- (c) $\text{Sn}(\text{CH}_3)_4$ (d) SnF_5^- (e) SnF_6^{2-}

10.51 In the gas phase, phosphorus pentachloride exists as separate molecules. In the solid phase, however, the compound is composed of alternating PCl_4^+ and PCl_6^- ions. What change(s) in molecular shape occur(s) as PCl_5 solidifies? How does the Cl—P—Cl angle change?

Molecular Shape and Molecular Polarity

(Sample Problem 10.9)

Concept Review Questions

10.52 For molecules of general formula AX_n (where $n > 2$), how do you determine if a particular molecule is polar?

10.53 How can a molecule with polar covalent bonds not be polar? Give an example.

10.54 Explain in general why the shape of a biomolecule is important to its function.

Skill-Building Exercises (grouped in similar pairs)

10.55 Consider the molecules SCl_2 , F_2 , CS_2 , CF_4 , and BrCl .

- (a) Which has bonds that are the most polar?
(b) Which molecules have a dipole moment?

10.56 Consider the molecules BF_3 , PF_3 , BrF_3 , SF_4 , and SF_6 .

- (a) Which has bonds that are the most polar?
(b) Which molecules have a dipole moment?

10.57 Which molecule in each pair has the greater dipole moment? Give the reason for your choice.

- (a) SO_2 or SO_3 (b) ICl or IF
(c) SiF_4 or SF_4 (d) H_2O or H_2S

10.58 Which molecule in each pair has the greater dipole moment? Give the reason for your choice.

- (a) ClO_2 or SO_2 (b) HBr or HCl
(c) BeCl_2 or SCl_2 (d) AsF_3 or AsF_5

Problems in Context

10.59 There are three different dichloroethylenes (molecular formula $\text{C}_2\text{H}_2\text{Cl}_2$), which we can designate X, Y, and Z. Compound X has no dipole moment, but compound Z does. Compounds X and Z each combine with hydrogen to give the same product:

What are the structures of X, Y, and Z? Would you expect compound Y to have a dipole moment?

10.60 Dinitrogen difluoride, N_2F_2 , is the only stable, simple inorganic molecule with an $\text{N}=\text{N}$ bond. It occurs in two forms: *cis* (both F atoms on the same side of the $\text{N}=\text{N}$ bond) and *trans* (the F atoms on opposite sides of the $\text{N}=\text{N}$ bond).

- (a) Draw the molecular shapes of the two forms of N_2F_2 .
(b) Predict the direction of the molecular polarity, if any, of each form.

Comprehensive Problems

10.61 In addition to ammonia, nitrogen forms three other hydrides: hydrazine (N_2H_4), diazene (N_2H_2), and tetrazene (N_4H_4).

(a) Use Lewis structures to compare the strength, length, and order of the nitrogen-nitrogen bonds in hydrazine, diazene, and N_2 .
 (b) Tetrazene (atom sequence H_2NNNNH_2) decomposes above 0°C to hydrazine and nitrogen gas. Draw a Lewis structure for tetrazene, and calculate $\Delta H^\circ_{\text{rxn}}$ for this decomposition.

10.62 Draw a Lewis structure for each species: (a) PF_5 ; (b) CCl_4 ; (c) H_3O^+ ; (d) ICl_3 ; (e) BeH_2 ; (f) PH_2^- ; (g) GeBr_4 ; (h) CH_3^- ; (i) BCl_3 ; (j) BrF_4^+ ; (k) XeO_3 ; (l) TeF_4 .

10.63 Give the molecular shape of each species in Problem 10.62.

10.64 Consider the following reaction of silicon tetrafluoride:

(a) Which depiction below best illustrates the change in molecular shape around Si? (b) Give the name and AX_mE_n designation of each shape in the depiction chosen in part (a).

10.65 Both aluminum and iodine form chlorides, Al_2Cl_6 and I_2Cl_6 , with “bridging” Cl atoms. The Lewis structures are

(a) What is the formal charge on each atom in molecule?
 (b) Which of these molecules has a planar shape? Explain.

10.66 The VSEPR model was developed before any xenon compounds had been prepared. Thus, these compounds provided an excellent test of the model’s predictive power. What would you have predicted for the shapes of XeF_2 , XeF_4 , and XeF_6 ?

10.67 When SO_3 gains two electrons, SO_3^{2-} forms. (a) Which depiction best illustrates the change in molecular shape around S?
 (b) Does molecular polarity change during this reaction?

10.68 The actual bond angle in NO_2 is 134.3° , and in NO_2^- it is 115.4° , although the ideal bond angle is 120° for both. Explain.

10.69 “Inert” xenon actually forms several compounds, especially with the highly electronegative elements oxygen and fluorine. The simple fluorides XeF_2 , XeF_4 , and XeF_6 are all formed by direct reaction of the elements. As you might expect from the size of the

xenon atom, the $\text{Xe}-\text{F}$ bond is not a strong one. Calculate the $\text{Xe}-\text{F}$ bond energy in XeF_6 , given that the enthalpy of formation is -402 kJ/mol .

10.70 Propylene oxide is used to make many products, including plastics such as polyurethane. One method for synthesizing it involves oxidizing propene with hydrogen peroxide:

(a) What are the molecular shape and ideal bond angle around each carbon atom in propylene oxide?

(b) Predict any deviation from the ideal for the actual $\text{C}-\text{C}-\text{C}$ bond angles (assume the three atoms in the ring form an equilateral triangle).

10.71 Chloral, $\text{Cl}_3\text{C}-\text{CH}=\text{O}$, reacts with water to form the sedative and hypnotic agent chloral hydrate, $\text{Cl}_3\text{C}-\text{CH}(\text{OH})_2$. Draw Lewis structures for these substances, and describe the change in molecular shape, if any, that occurs around each of the carbon atoms during the reaction.

10.72 Like several other bonds, carbon-oxygen bonds have lengths and strengths that depend on the bond order. Draw Lewis structures for the following species, and arrange them in order of increasing carbon-oxygen bond length and then by increasing carbon-oxygen bond strength: (a) CO ; (b) CO_3^{2-} ; (c) H_2CO ; (d) CH_4O ; (e) HCO_3^- (H attached to O).

10.73 In the 1980s, there was an international agreement to destroy all stockpiles of mustard gas, $\text{ClCH}_2\text{CH}_2\text{SCH}_2\text{CH}_2\text{Cl}$. When this substance contacts the moisture in eyes, nasal passages, and skin, the $-\text{OH}$ groups of water replace the Cl atoms and create high local concentrations of hydrochloric acid, which cause severe blistering and tissue destruction. Write a balanced equation for this reaction, and calculate $\Delta H^\circ_{\text{rxn}}$.

10.74 The four bonds of carbon tetrachloride (CCl_4) are polar, but the molecule is nonpolar because the bond polarity is canceled by the symmetrical tetrahedral shape. When other atoms substitute for some of the Cl atoms, the symmetry is broken and the molecule becomes polar. Use Figure 9.20 to rank the following molecules from the least polar to the most polar: CH_2Br_2 , CF_2Cl_2 , CH_2F_2 , CH_2Cl_2 , CBr_4 , CF_2Br_2 .

10.75 Ethanol ($\text{CH}_3\text{CH}_2\text{OH}$) is being used as a gasoline additive or alternative in many parts of the world.

(a) Use bond energies to find $\Delta H^\circ_{\text{rxn}}$ for the combustion of gaseous ethanol. (Assume H_2O forms as a gas.)

(b) In its standard state at 25°C , ethanol is a liquid. Its vaporization requires 40.5 kJ/mol . Correct the value from part (a) to find the enthalpy of reaction for the combustion of liquid ethanol.

(c) How does the value from part (b) compare with the value you calculate from standard enthalpies of formation (Appendix B)?

(d) “Greener” methods produce ethanol from corn and other plant material, but the main industrial method involves hydrating ethylene from petroleum. Use Lewis structures and bond energies to calculate $\Delta H^\circ_{\text{rxn}}$ for the formation of gaseous ethanol from ethylene gas with water vapor.

10.76 In each of the following compounds, the C atoms form a single ring. Draw a Lewis structure for each molecule, identify cases for which resonance exists, and determine the carbon-carbon bond order(s): (a) C_3H_4 ; (b) C_3H_6 ; (c) C_4H_6 ; (d) C_4H_4 ; (e) C_6H_6 .

10.77 An experiment requires 50.0 mL of 0.040 M NaOH for the titration of 1.00 mmol of acid. Mass analysis of the acid shows 2.24% hydrogen, 26.7% carbon, and 71.1% oxygen. Draw the Lewis structure of the acid.

10.78 A gaseous compound has a composition by mass of 24.8% carbon, 2.08% hydrogen, and 73.1% chlorine. At STP, the gas has a density of 4.3 g/L. Draw a Lewis structure that fits these facts. Would another structure be equally satisfactory? Explain.

10.79 Perchlorates are powerful oxidizing agents used in fireworks, flares, and the booster rockets of space shuttles. Lewis structures for the perchlorate ion (ClO_4^-) can be drawn with all single bonds or with one, two, or three double bonds. Draw each of these possible resonance forms, use formal charges to determine the more important structure, and calculate its average bond order.

10.80 Methane burns in oxygen to form carbon dioxide and water vapor. Hydrogen sulfide burns in oxygen to form sulfur dioxide and water vapor. Use bond energies (Table 9.2) to determine the enthalpy of each reaction per mole of O_2 (assume Lewis structures with zero formal charges; BE of $\text{S}=\text{O}$ is 551 kJ/mol).

10.81 Use Lewis structures to determine which *two* of the following are unstable: (a) SF_2 ; (b) SF_3 ; (c) SF_4 ; (d) SF_5 ; (e) SF_6 .

10.82 A major short-lived, neutral species in flames is OH.

(a) What is unusual about the electronic structure of OH?
 (b) Use the standard enthalpy of formation of OH(g) (39.0 kJ/mol) and bond energies to calculate the O—H bond energy in OH(g) .
 (c) From the average value for the O—H bond energy in Table 9.2 and your value for the O—H bond energy in OH(g) , find the energy needed to break the first O—H bond in water.

10.83 Pure HN_3 (atom sequence HNNN) is explosive. In aqueous solution, it is a weak acid that yields the azide ion, N_3^- . Draw resonance structures to explain why the nitrogen-nitrogen bond lengths are equal in N_3^- but unequal in HN_3 .

10.84 Except for nitrogen, the elements of Group 15 all form pentafluorides, and most form pentachlorides. The chlorine atoms of PCl_5 can be replaced with fluorine atoms one at a time to give, successively, PCl_4F , PCl_3F_2 , . . . , PF_5 . (a) Given the sizes of F and Cl, would you expect the first two F substitutions to be at axial or equatorial positions? Explain. (b) Which of the five fluorine-containing molecules have no dipole moment?

10.85 Dinitrogen monoxide (N_2O) supports combustion in a manner similar to oxygen, with the nitrogen atoms forming N_2 . Draw three resonance structures for N_2O (one N is central), and use formal charges to decide the relative importance of each. What correlation can you suggest between the more important structure and the observation that N_2O supports combustion?

10.86 Oxalic acid ($\text{H}_2\text{C}_2\text{O}_4$) is found in toxic concentrations in rhubarb leaves. The acid forms two ions, HC_2O_4^- and $\text{C}_2\text{O}_4^{2-}$, by the sequential loss of H^+ ions. Draw Lewis structures for the three species, and comment on the relative lengths and strengths of their carbon-oxygen bonds. The connections among the atoms are shown below with single bonds only.

10.87 The Murchison meteorite that landed in Australia in 1969 contained 92 different amino acids, including 21 found in Earth organisms. A skeleton structure (single bonds only) of one of these extraterrestrial amino acids is shown below.

Draw a Lewis structure, and identify any atoms having a nonzero formal charge.

10.88 Hydrazine (N_2H_4) is used as a rocket fuel because it reacts very exothermically with oxygen to form nitrogen gas and water vapor. The heat released and the increase in number of moles of gas provide thrust. Calculate the enthalpy of reaction.

10.89 A student isolates a product with the molecular shape shown at right (F is green). (a) If the species is a neutral compound, can the black sphere represent selenium (Se)? (b) If the species is an anion, can the black sphere represent N? (c) If the black sphere represents Br, what is the charge of the species?

10.90 When gaseous sulfur trioxide is dissolved in concentrated sulfuric acid, disulfuric acid forms:

Use bond energies (Table 9.2) to determine $\Delta H_{\text{rxn}}^\circ$. (The S atoms in $\text{H}_2\text{S}_2\text{O}_7$ are bonded through an O atom. Assume Lewis structures with zero formal charges; BE of $\text{S}=\text{O}$ is 551 kJ/mol.)

10.91 A molecule of formula AY_3 is found experimentally to be polar. Which molecular shapes are possible and which are impossible for AY_3 ?

10.92 Consider the following molecular shapes:

(a) Match each shape with one of the following species: XeF_3^+ , SbBr_3 , GaCl_3 .

(b) Which, if any, is polar?

(c) Which has the most valence electrons around the central atom?

10.93 Hydrogen cyanide can be catalytically reduced with hydrogen to form methylamine. Use Lewis structures and bond energies to determine $\Delta H_{\text{rxn}}^\circ$ for

10.94 Ethylene, C_2H_4 , and tetrafluoroethylene, C_2F_4 , are used to make the polymers polyethylene and polytetrafluoroethylene (Teflon), respectively.

(a) Draw the Lewis structures for C_2H_4 and C_2F_4 , and give the ideal $\text{H}-\text{C}-\text{H}$ and $\text{F}-\text{C}-\text{F}$ bond angles.

(b) The actual $\text{H}-\text{C}-\text{H}$ and $\text{F}-\text{C}-\text{F}$ bond angles are 117.4° and 112.4° , respectively. Explain these deviations.

10.95 Using bond lengths in Table 9.2 and assuming ideal bond angles, calculate each of the following distances:

(a) Between H atoms in C_2H_2

(b) Between F atoms in SF_6 (two answers)

(c) Between equatorial F atoms in PF_5

10.96 Phosphorus pentachloride, a key industrial compound with annual world production of about 2×10^7 kg, is used to make other compounds. It reacts with sulfur dioxide to produce phosphorus oxychloride (POCl_3) and thionyl chloride (SOCl_2). Draw a Lewis structure and name the molecular shape of each of these products.

- › atomic orbital shapes (Section 7.4)
- › Pauli exclusion principle (Section 8.1)
- › Hund's rule (Section 8.2)
- › Lewis structures (Section 10.1)
- › resonance in covalent bonding (Section 10.1)
- › molecular shapes (Section 10.2)
- › molecular polarity (Section 10.3)

Chemists have found that they cannot explain all observations about bonding with one model. All scientific models have limitations because they are simplifications of reality. The VSEPR theory, covered in Chapter 10, accounts for molecular shapes, but it doesn't explain how they arise from atomic orbitals. After all, the orbitals described in Chapter 7 aren't oriented toward the corners of a tetrahedron, like the one for carbon in CH_4 . Moreover, knowing the shape doesn't help us explain the magnetic and spectral properties of a molecule such as O_2 . Liquid oxygen has a very interesting property—it is attracted to the poles of a magnet (*photo*) because O_2 molecules have unpaired electrons. But the Lewis structure we draw for O_2 indicates that all of the molecule's electrons are paired. We need an understanding of orbitals and energy levels to explain oxygen's magnetic property.

The two theories presented in this chapter focus on different questions and complement each other. Don't be concerned that we need several models to explain a complex phenomenon like bonding. In every science, one model may account for some aspect of a topic better than another, and several are employed to explain a wider range of phenomena.

IN THIS CHAPTER . . . We introduce two theories of bonding in molecules that are based on the interactions of the orbitals of their atoms.

- › We discuss valence bond (VB) theory, which rationalizes molecular shapes through interactions of atomic orbitals during bonding to form hybrid orbitals.
- › We apply VB theory to sigma and pi bonds, the two types of covalent bonds.
- › We see why parts of molecules don't rotate freely around multiple bonds, which has major effects on reactivity, physical properties, and biological behavior.
- › We discuss molecular orbital (MO) theory, which explains molecular energy levels and properties based on the formation of orbitals that spread over a whole molecule.
- › We apply MO theory to understand key properties of some diatomic and simple polyatomic molecules.

11.1 VALENCE BOND (VB) THEORY AND ORBITAL HYBRIDIZATION

What *is* a covalent bond, and what characteristic gives it strength? And how can we explain *molecular* shapes based on the interactions of *atomic* orbitals? One very useful approach for answering these questions is based on quantum mechanics (Chapter 7) and is called **valence bond (VB) theory**.

The Central Themes of VB Theory

The basic principle of VB theory is that *a covalent bond forms when orbitals of two atoms overlap and a pair of electrons occupy the overlap region*. In the terminology of quantum mechanics, overlap of the two orbitals means their wave functions are *in phase* (constructive interference; see Figure 7.5), so the amplitude between the nuclei increases. The central themes of VB theory derive from this principle:

1. *Opposing spins of the electron pair.* As the Pauli exclusion principle (Section 8.1) requires, the space formed by the overlapping orbitals *has a maximum capacity for two*

A Hydrogen, H_2 

B Hydrogen fluoride, HF

C Fluorine, F_2

Figure 11.1 Orbital overlap and spin pairing in three diatomic molecules. (In **B** and **C**, the $2p_x$ orbital is shown involved in the bonding; the other two $2p$ orbitals of F are omitted for clarity.)

electrons that have opposite (paired) spins. In the simplest case, a molecule of H_2 forms when the $1s$ orbitals of two H atoms overlap, and the electrons, with their spins paired, spend more time in the overlap region (up and down arrows in Figure 11.1A).

2. *Maximum overlap of bonding orbitals.* Bond strength depends on the attraction between nuclei and shared electrons, so *the greater the orbital overlap, the closer the nuclei are to the electrons, and the stronger the bond.* Extent of overlap depends on orbital shape and direction. An s orbital is spherical, but p and d orbitals have specified directions. Thus, a p or d orbital involved in a bond is oriented so as to *maximize overlap*. In HF, for example, the $1s$ orbital of H overlaps a half-filled $2p$ orbital of F *along its long axis* (Figure 11.1B). In F_2 , the two half-filled $2p$ orbitals interact end to end, that is, *along their long axes* (Figure 11.1C).

3. *Hybridization of atomic orbitals.* To account for the bonding in diatomic molecules like HF and F_2 , we picture direct overlap of s and/or p orbitals of isolated atoms. But how can we account for the shape of a molecule like methane from the shapes and orientations of C and H atomic orbitals? A C atom ($[\text{He}] 2s^2 2p^2$) has two valence electrons in the spherical $2s$ orbital and one valence electron in two of the three mutually perpendicular $2p$ orbitals. If the two half-filled p orbitals overlapped the $1s$ orbitals of two H atoms, *two* C—H bonds would form with a 90° H—C—H bond angle. But methane has the formula CH_4 , not CH_2 , and its bond angles are 109.5° .

To explain such facts, Linus Pauling proposed that, during bonding, *the valence orbitals in the isolated atoms become new orbitals in the molecule.* Quantum-mechanical calculations show that, if we mathematically “mix” certain combinations of orbitals, we form new ones whose spatial orientations *do* match the observed molecular shapes. The process of orbital mixing is called **hybridization**, and the new atomic orbitals are called **hybrid orbitals**.

Here are some central points about the hybrid orbitals that form during bonding:

- The *number* of hybrid orbitals formed *equals* the number of atomic orbitals mixed.
- The *type* of hybrid orbitals formed *varies* with the types of atomic orbitals mixed.
- The *shape* and *orientation* of a hybrid orbital *maximize* its overlap with the orbital of the other atom in the bond.

It is useful to think of hybridization as a process in which atomic orbitals mix, hybrid orbitals form, they overlap other orbitals, and electrons enter the overlap region with opposing spins, thus forming stable bonds. In truth, hybridization is a mathematical concept that helps us explain the molecular shapes we observe.

Types of Hybrid Orbitals

We postulate the type of hybrid orbitals in a molecule *after* we observe its shape. Note that the orientations of the five types of hybrid orbitals we discuss next correspond to the five electron-group arrangements in VSEPR theory (see Figure 10.2).

sp Hybridization We will start with BeCl_2 , a molecule in which the central atom Be is surrounded by two electron groups in a linear arrangement. Let's first examine the need for the concept of hybridization to account for the bonding in this molecule:

- The two valence electrons of Be are paired in the $2s$ orbital ($[\text{He}] 2s^2$) in the ground state.
- Thus, Be does not have unpaired electrons to pair with the $3p$ unpaired electron in Cl atoms ($[\text{Ne}] 3s^2 3p^5$) to form bonds.
- The Be atom can promote an electron from the $2s$ orbital to an empty $2p$ orbital, resulting in two unpaired electrons that could participate in two bonds with Cl atoms to form BeCl_2 .
- This would result in two nonidentical bonds: the $2s$ orbital of Be would overlap with a $3p$ orbital of one Cl atom to form one bond, while the $2p$ orbital of Be would overlap with a $3p$ orbital of a second Cl atom to form the second bond. But, experimentally, we know that the two Be—Cl bonds are identical in length and energy.

Figure 11.2 Formation and orientation of sp hybrid orbitals and the bonding in BeCl_2 . **A**, One $2s$ and one $2p$ atomic orbital mix to form two sp hybrid orbitals. (The simplified hybrid orbitals at *far right* are used elsewhere, often even without the small lobe.) **B**, The orbital box diagram for hybridization of Be, drawn vertically. (Full color, light shading, or no shading indicates orbital occupancy.) **C**, The orbital box diagram with orbital contours. **D**, Overlap of Be and Cl orbitals to form BeCl_2 . (Simplified hybrid orbitals are shown for Be; only the $3p$ orbital of Cl that is involved in bonding is shown.)

- The concept of hybridization offers an explanation for the linear shape and identical bonds in BeCl_2 .

1. *Orbitals mixed and orbitals formed.* VB theory proposes that two *nonequivalent* orbitals of a central atom, one s and one p , mix and form two *equivalent sp hybrid orbitals* that are oriented 180° apart (Figure 11.2A). The shape of these hybrid orbitals, with one large and one small lobe, differs markedly from the shapes of the atomic orbitals that were mixed. The orientation of these orbitals increases electron density in the *bonding direction* and minimizes repulsions between the electrons that occupy the orbitals.

2. *Overlap of orbitals from central and surrounding atoms: BeCl_2 .* In beryllium chloride, the Be atom is sp hybridized. Figure 11.2B depicts the hybridization of Be in an orbital box diagram, and Figure 11.2C shows an orbital box diagram with shaded contours instead of arrows. Bond formation with Cl is shown in Figure 11.2D:

- The filled $2s$ and one of the three empty $2p$ orbitals of Be mix and form two half-filled sp orbitals.
- Two empty unhybridized $2p$ orbitals of Be lie perpendicular to each other and to the sp hybrids.
- The hybrid orbitals overlap the half-filled $3p$ orbital in each of two Cl atoms (Cl: $[\text{Ne}] 3s^2 3p^5$).
- The four electrons—two from Be and one from each Cl—appear as pairs with opposite spins in the two overlap regions. (The $3p$ and sp hybrid orbitals that are in light shades on the left in Figure 11.2D become fully colored on the right, after the bonds form and each orbital is filled with two electrons.)

sp^2 Hybridization We use another type of orbital hybridization to explain the two shapes possible for the trigonal planar electron-group arrangement (trigonal planar and bent).

1. *Orbitals mixed and orbitals formed.* Mixing one s and two p orbitals gives three **sp^2 hybrid orbitals** that point to the corners of an equilateral triangle, their axes 120° apart. (In hybrid-orbital notations, unlike in electron configurations, superscripts indicate the number of *atomic orbitals* of a given type, *not* the number of *electrons* in the orbital: thus, one s and two p orbitals give $s^1 p^2$, or sp^2 .) The third $2p$ orbital remains unhybridized.

2. *Overlap of orbitals from central and surrounding atoms: BF_3 (trigonal planar).* Boron ($[\text{He}] 2s^2 2p^1$), with only one unpaired electron in the ground state, must have three half-filled orbitals to form the three bonds in BF_3 . The boron atom is sp^2 hybridized, with the three sp^2 orbitals in a trigonal plane and the third $2p$ orbital unhybridized and perpendicular to this plane (Figure 11.3). Each half-filled sp^2 orbital overlaps the half-filled $2p$ orbital of an F atom, and the six valence electrons—three from B and one from each of the three F atoms—form three bonding pairs.

3. *Placement of lone pairs.* To account for other molecular shapes associated with a given electron-group arrangement, one or more hybrid orbitals contains a lone pair.

Figure 11.3 The sp^2 hybrid orbitals in BF_3 . **A**, The orbital box diagram shows the formation of three sp^2 hybrid orbitals. One $2p$ orbital is unhybridized and empty. **B**, Contour depiction of BF_3 .

Figure 11.4 The sp^3 hybrid orbitals in CH_4 . **A**, The orbital box diagram shows formation of four sp^3 hybrids. **B**, Contour depiction of CH_4 , with electron pairs shown as dots.

In ozone (O_3), for example, the shape is bent because the central O is sp^2 hybridized; two of the sp^2 hybrid orbitals are involved in the bonds to the other two oxygen atoms and a lone pair fills the third sp^2 orbital of the central O atom.

sp^3 Hybridization Let's return to the question posed earlier about the shape of methane. The type of hybridization that accounts for methane's shape applies to any species with a tetrahedral electron-group arrangement.

1. *Orbitals mixed and orbitals formed.* Mixing one s and three p orbitals gives four sp^3 **hybrid orbitals** that point to the corners of a tetrahedron.

2. *Overlap of orbitals from central and surrounding atoms:* CH_4 . Carbon ($[\text{He}] 2s^2 2p^2$), with only two unpaired electrons in the ground state, must have four half-filled orbitals to form the four bonds in CH_4 . The C atom in methane is sp^3 hybridized. Its four valence electrons half-fill the four sp^3 hybrids, which overlap the half-filled $1s$ orbitals of four H atoms to form four C—H bonds (Figure 11.4).

3. *Placement of lone pairs.* The trigonal pyramidal shape of NH_3 arises because the three half-filled sp^3 hybrid orbitals form the three N—H bonds and a lone pair fills the fourth sp^3 orbital. The bent shape of H_2O arises because lone pairs fill any two of the sp^3 orbitals of O (Figure 11.5).

4. *Bond angles and hybridization.* Examination of the electron configurations of isolated N and O atoms in Figure 11.5 raises a question. Nitrogen atoms have three unpaired electrons in the $2p$ sublevel, which could participate in the three bonds in NH_3 , and oxygen atoms have two unpaired $2p$ electrons, which could participate in the two bonds in H_2O . Why use the concept of hybridization to explain the bonding in these two molecules? The answer lies in the bond angles in these species. If N and O atoms

Figure 11.5 The sp^3 hybrid orbitals in NH_3 and H_2O . **A**, The orbital box diagrams show sp^3 hybridization, with lone pairs filling one (in NH_3) or two (in H_2O) hybrid orbitals. **B**, Contour depictions of NH_3 and H_2O .

Figure 11.6 The sp^3d hybrid orbitals in PCl_5 . **A**, The orbital box diagram shows the formation of five half-filled sp^3d orbitals. Four $3d$ orbitals are unhybridized and empty. **B**, Contour depiction of PCl_5 . (For clarity, the unhybridized $3d$ orbitals of P, the other two $3p$ orbitals of Cl, and the five bonding P—Cl pairs are not shown.)

overlapped their half-filled p orbitals with the $1s$ orbitals of H, the resulting bond angles (H—N—H or H—O—H) would be 90° , since p orbitals are perpendicular to each other. But the bond angles in NH_3 and H_2O are 107.3° and 104.5° , respectively, a fact that is better explained by the tetrahedral arrangement of four sp^3 hybrid orbitals in these molecules.

sp^3d Hybridization Molecules with shapes due to the trigonal bipyramidal electron-group arrangement (trigonal bipyramidal, seesaw, T-shaped, and linear) must have central atoms from Period 3 or higher, because d orbitals, as well as s and p orbitals, are mixed to form the hybrid orbitals.

1. *Orbitals mixed and orbitals formed.* Mixing one $3s$, the three $3p$, and one of the five $3d$ orbitals gives five **sp^3d hybrid orbitals**, which point to the corners of a trigonal bipyramid, accommodating five electron groups.

2. *Overlap of orbitals from central and surrounding atoms:* PCl_5 . The P atom in PCl_5 is sp^3d hybridized. Each hybrid orbital overlaps a $3p$ orbital of a Cl atom, and 10 valence electrons—5 from P and 1 from each of the five Cl atoms—form five P—Cl bonds (Figure 11.6).

3. *Placement of lone pairs.* Seesaw, T-shaped, and linear molecules have lone pairs in one, two, or three of the central atom's sp^3d orbitals, respectively. Figure 11.7 shows the bonding for the T-shaped molecule ClF_3 .

Figure 11.7 The sp^3d hybrid orbitals in ClF_3 . **A**, The orbital box diagram shows sp^3d hybridization. **B**, Contour depiction of ClF_3 , with lone pairs filling two hybrid orbitals. (For clarity, the unhybridized $3d$ orbitals of Cl, the other two $2p$ orbitals of F, and the three bonding Cl—F pairs are not shown.)

sp^3d^2 Hybridization The VB model proposes that molecules with shapes corresponding to the octahedral electron-group arrangement use two d orbitals in the formation of six hybrid orbitals to accommodate six electron groups.

1. *Orbitals mixed and orbitals formed.* Mixing one $3s$, the three $3p$, and two $3d$ orbitals gives six **sp^3d^2 hybrid orbitals**, which point to the corners of an octahedron.

Figure 11.8 The sp^3d^2 hybrid orbitals in SF_6 . **A**, The orbital box diagram shows formation of six half-filled sp^3d^2 orbitals; three $3d$ orbitals remain unhybridized and empty. **B**, Contour depiction of SF_6 .

2. *Overlap of orbitals from central and surrounding atoms: SF_6 .* The S atom in SF_6 is sp^3d^2 hybridized. Each half-filled hybrid orbital overlaps a half-filled $2p$ orbital of an F atom, and 12 valence electrons—6 from S and 1 from each of the six F atoms—form six S—F bonds (Figure 11.8).

3. *Placement of lone pairs.* Square pyramidal and square planar molecules have lone pairs in one and two of the central atom's sp^3d^2 orbitals, respectively.

Table 11.1 summarizes the numbers and types of atomic orbitals that mix to form the five types of hybrid orbitals. Once again, note the similarities between hybrid-orbital orientations and the shapes predicted by VSEPR theory. Figure 11.9 shows three conceptual steps from a molecular formula to the hybrid orbitals in the molecule, and Sample Problem 11.1 focuses on the last step of that process.

Table 11.1 | Composition and Orientation of Hybrid Orbitals

	Linear	Trigonal Planar	Tetrahedral	Trigonal Bipyramidal	Octahedral
Atomic orbitals mixed	one s one p	one s two p	one s three p	one s three p one d	one s three p two d
Hybrid orbitals formed	two sp	three sp^2	four sp^3	five sp^3d	six sp^3d^2
Unhybridized orbitals remaining	two p	one p	none	four d	three d
Orientation of hybrid orbitals

Student Hot Spot

Student data indicate that you may struggle with the concept of orbital hybridization. Access the eBook to view an additional Learning Resource video on this topic.

SAMPLE PROBLEM 11.1 | Postulating Hybrid Orbitals in a Molecule

Problem Use partial orbital diagrams to describe how mixing the atomic orbitals of the central atom(s) leads to the hybrid orbitals in each of the following:

(a) Methanol, CH_3OH

(b) Sulfur tetrafluoride, SF_4

Plan We use the molecular formula to draw the Lewis structure and determine the electron-group arrangement of each central atom. Then we use Table 11.1 to postulate the type of hybrid orbitals. We write the partial orbital diagram for each central atom before and after the orbitals are hybridized.

Solution

(a) The Lewis structure of CH_3OH shows that the C and O atoms each have four electron groups, with a tetrahedral electron-group arrangement around both atoms:

Since the C and O atoms both have four electron groups, they each need four hybrid orbitals to accommodate those groups and have therefore each mixed one $2s$ and three $2p$ to form four sp^3 hybrid orbitals. The C atom has four half-filled sp^3 orbitals to form the four bonds:

The O atom has two half-filled sp^3 orbitals that are used to form two bonds and two sp^3 orbitals filled with lone pairs:

(b) The Lewis structure of SF_4 shows that S has four bonds and one lone pair, for a total of five electron groups. The electron-group arrangement is trigonal bipyramidal, so the central S atom is sp^3d hybridized, which means one $3s$, three $3p$, and one $3d$ orbital were mixed. One of the hybrid orbitals is filled with a lone pair, and four are half-filled and used to form four bonds to F atoms. Four unhybridized $3d$ orbitals remain empty:

FOLLOW-UP PROBLEMS

Brief Solutions for **all** Follow-up Problems appear at the end of the chapter.

11.1A What is the hybridization of the central atom in each of the following? Use partial orbital diagrams to show how the atomic orbitals of the central atom mix to form hybrid orbitals in (a) beryllium fluoride, BeF_2 ; (b) silicon tetrachloride, SiCl_4 ; (c) xenon tetrafluoride, XeF_4 .

11.1B What is the hybridization of the central atom in each of the following? Use partial orbital diagrams to show how the atomic orbitals of the central atom mix to form hybrid orbitals in (a) aluminum iodide, AlI_3 (Al is electron deficient); (b) phosphorus trichloride, PCl_3 ; (c) krypton difluoride, KrF_2 .

SOME SIMILAR PROBLEMS 11.7–11.12 and 11.15–11.18

Limitations to the Concept of Hybridization We rely on the VSEPR and VB theories to explain an observed molecular shape. In some cases, however, the theories may not be consistent with other findings.

1. *Hybridization does not apply: large nonmetal hydrides.* Consider the Lewis structure and bond angle of H_2S :

Based on VSEPR theory, we would predict that, as in H_2O , the four electron groups around H_2S point to the corners of a tetrahedron, and the two lone pairs compress the $\text{H}-\text{S}-\text{H}$ bond angle below the ideal 109.5° . Based on VB theory, we would propose that the $3s$ and $3p$ orbitals of the S atom mix and form four sp^3 hybrids, two of which are filled with lone pairs, while the other two overlap $1s$ orbitals of two H atoms and are filled with bonding pairs.

But observation does *not* support these arguments. The bond angle of 92° is close to the 90° angle between *unhybridized* p orbitals. Similar angles occur in the hydrides of other large nonmetals of Groups 15 and 16. Why apply a theory if the facts don't warrant it? Real factors—bond length, atomic size, and electrostatic repulsions—influence shape. Larger atoms form longer bonds to H, which decreases repulsions; thus, overlap of *unhybridized* orbitals adequately explains these shapes.

2. *d-Orbital hybridization is less important: shapes with expanded valence shells.* VB theory proposes the formation of sp^3d and sp^3d^2 hybrid orbitals in shapes with expanded valence shells. But recent quantum-mechanical calculations have shown that d orbitals have such high energies that they do not hybridize effectively with the *much* more stable s and p orbitals of a given n value. Thus, for example, it now appears that SF_6 does not utilize sp^3d^2 hybrids in bonding; instead, some have proposed that SF_6 is most stable when the bonding orbitals of the central S use a combination of sp hybrid orbitals and unhybridized $3p$ orbitals. Others prefer explanations that involve molecular orbitals or even ionic structures. We must remember that molecules do not have to follow our models; instead, we must recognize the limits of our models and adjust them in light of new information. Since VB theory does successfully explain the molecular geometries of molecules with expanded valence shells, in this text we will continue to use the traditional approach of including d -orbital hybridization for molecules with expanded valence shells for simplicity, recognizing the limitations of this approach.

› Summary of Section 11.1

- › VB theory explains that a covalent bond forms when two atomic orbitals overlap and two electrons with paired (opposite) spins occupy the overlap region.
- › To explain molecular shape, VB theory proposes that, during bonding, atomic orbitals mix to form hybrid orbitals whose shape and orientation differ from those of the mixed atomic orbitals. This process gives rise to greater orbital overlap and, thus, stronger bonds.
- › Based on an observed molecular shape (and the related electron-group arrangement), we postulate the type of hybrid orbital that accounts for that shape. In many cases, especially for molecules with larger central atoms, the concept of hybridization has major limitations.

11.2 MODES OF ORBITAL OVERLAP AND THE TYPES OF COVALENT BONDS

Orbitals can overlap by two *modes*—end to end or side to side—which gives rise to two types of covalent bonds—*sigma* and *pi*. We'll use VB theory to describe the two types here; as you'll see, they are described by molecular orbital theory as well.

Orbital Overlap in Single and Multiple Bonds

Ethane (C_2H_6), ethylene (C_2H_4), and acetylene (C_2H_2) have different shapes. Ethane is tetrahedral at both carbons with bond angles near the ideal 109.5° . Ethylene is trigonal planar at both carbons with bond angles near the ideal 120° . Acetylene is linear with bond angles of 180° :

In these molecules, two modes of orbital overlap result in two types of bonds.

End-to-End Overlap and Sigma (σ) Bonding Both C atoms of ethane are sp^3 hybridized; the four valence electrons of C half-fill the four sp^3 orbitals. The C—C bond arises from overlap of the end of one sp^3 orbital on one C atom with the end of one sp^3 orbital on the other C atom (Figure 11.10). Each of the six C—H bonds is formed by the overlap of the end of a sp^3 hybrid orbital on the C atom with the $1s$ orbital of a hydrogen atom. Each bond in ethane is a **sigma (σ) bond**:

- A sigma bond is formed by *end-to-end* overlap of orbitals.
- A sigma bond has its *highest electron density along the bond axis* and is shaped like an ellipse rotated about its long axis (like a football).
- *All single bonds are σ bonds.*

Figure 11.10 The σ bonds in ethane (C_2H_6). **A**, Depiction using atomic contours. **B**, An electron density model shows very slightly positive (*blue*) and negative (*red*) regions. **C**, Wedge-bond perspective drawing of the ethane molecule.

Side-to-Side Overlap and Pi (π) Bonding For this type of bonding, we'll examine ethylene and acetylene:

1. *In ethylene*, each C atom is surrounded by three electron groups and is sp^2 hybridized. The four valence electrons of C half-fill the three sp^2 orbitals *and* the unhybridized $2p$ orbital. The unhybridized $2p$ orbital lies perpendicular to the sp^2 plane (Figure 11.11). Two sp^2 orbitals of each C form C—H σ bonds. The third sp^2 orbital forms a σ bond with the other C. With the σ -bonded C atoms near each other, a second bond is formed between the two C atoms when their half-filled unhybridized $2p$ orbitals overlap to form a **pi (π) bond**:

- A pi bond is formed by *side-to-side* overlap of orbitals.
- A pi bond has *two regions (lobes) of electron density*, one above and one below the σ -bond axis. *The two electrons in one π bond occupy both lobes.*

Figure 11.11 The σ and π bonds in ethylene (C_2H_4). **A**, The C—C σ bond and the four C—H σ bonds are shown with the unhybridized $2p$ orbitals. **B**, An accurate depiction of the $2p$ orbitals shows the side-to-side overlap; σ bonds are shown with a ball-and-stick model. **C**, Two overlapping regions constitute *one* π bond, which is occupied by two electrons. **D**, With four electrons (one σ bond and one π bond) between the C atoms, electron density (red) is higher there. **E**, Wedge-bond perspective drawing of the ethylene molecule.

- A double bond consists of one σ bond and one π bond, which increases electron density between the nuclei (see Figure 11.11D). The two electron pairs act as one electron group because each pair occupies a different orbital, which reduces repulsions.

2. In *acetylene*, each C atom is surrounded by two electron groups and is sp hybridized, and its four valence electrons half-fill the two sp hybrids and the two unhybridized $2p$ orbitals. Each C forms a C—H σ bond with one sp orbital and a C—C σ bond with the other (Figure 11.12). Side-to-side overlap of one pair of unhybridized $2p$ orbitals gives one π bond, with electron density above and below the σ bond. Side-to-side overlap of the other pair of unhybridized $2p$ orbitals gives another π bond, 90° away from the first, with electron density in front and back of the σ bond. The result is a *cylindrically symmetrical* $\text{H—C}\equiv\text{C—H}$ molecule. Note the greater electron density between the C atoms created by the six bonding electrons.

- A triple bond consists of one σ and two π bonds.

Figure 11.12 The σ bonds and π bonds in acetylene (C_2H_2). **A**, A contour depiction shows the C—C σ bond, the two C—H σ bonds, and two unhybridized $2p$ orbitals (one pair is in red for clarity). **B**, The $2p$ orbitals (accurate form) overlap side to side; σ bonds are shown with a ball-and-stick model. **C**, Overlapping regions of two π bonds, one black and the other red. **D**, The molecule has cylindrical symmetry. Six electrons (one σ bond and two π bonds) create even higher electron density (red) between the C atoms. **E**, Bond-line drawing of the acetylene molecule.

Mode of Overlap, Bond Strength, and Bond Order Because orbitals overlap less side to side than they do end to end, a π bond is weaker than a σ bond; thus, for carbon-carbon bonds, a double bond is less than twice as strong as a single bond (Table 9.2). Figure 11.13 shows electron density relief maps of the three types of carbon-carbon bonds; note the increasing electron density between the nuclei from single to double to triple bond.

Lone-pair repulsions, bond polarities, and other factors affect overlap between other pairs of atoms. Nevertheless, as a rough approximation, in terms of bond order (BO), a double bond ($\text{BO} = 2$) is about twice as strong as a single bond ($\text{BO} = 1$), and a triple bond ($\text{BO} = 3$) is about three times as strong.

Figure 11.13 Electron density and bond order in ethane, ethylene, and acetylene.**SAMPLE PROBLEM 11.2****Describing the Types of Orbitals and Bonds in Molecules****Problem (a)** Describe the types of orbitals and bonds in acetone, $(\text{CH}_3)_2\text{CO}$.**(b)** Methyl anthranilate, whose structure is shown, is used to provide grape flavor in candy and beverages. Give the type of hybrid orbitals used by the numbered C atoms (C_1 and C_2), the N atom, and the two O atoms, and give the number of π bonds in the molecule.**Plan (a)** We use the shape around each central atom to postulate the hybrid orbitals involved and use unhybridized orbitals to form the C—O bond. **(b)** We use the shape around each atom to postulate the hybrid orbitals involved; to count the π bonds, we recall that a double bond is 1 σ bond and 1 π bond.**Solution (a)** The shapes are tetrahedral around each C of the two CH_3 (methyl) groups and trigonal planar around the middle C (see Sample Problem 10.8). Thus, the middle C has three sp^2 orbitals and one unhybridized p orbital. Each of the two methyl C atoms has four sp^3 orbitals. Three of these form σ bonds with the $1s$ orbitals of H atoms; the fourth forms a σ bond with an sp^2 orbital of the middle C. Thus, two of the three sp^2 orbitals of the middle C form σ bonds to the other two C atoms.The O atom is also sp^2 hybridized and has an unhybridized p orbital that can form a π bond. Two of the O atom's sp^2 orbitals hold lone pairs, and the third forms a σ bond with the third sp^2 orbital of the middle C atom. The unhybridized, half-filled $2p$ orbitals of C and O form a π bond. The σ and π bonds constitute the C=O bond:**(b)** C_1 , with three electron groups, has a trigonal planar shape and sp^2 hybrid orbitals; the C_2 , N, and single-bonded O atoms all have four electron groups and a tetrahedral electron-group arrangement and use sp^3 hybrid orbitals. The O atom involved in the double bond has three electron groups, a trigonal planar electron-group arrangement, and sp^2 hybrid orbitals. There are four double bonds in the molecule (three C=C bonds and one C=O bond), so there are four π bonds.**Comment** Why is the O atom in acetone hybridized? After all, it could use two perpendicular p orbitals for the σ and π bonds with C and leave the other p and the s orbital to hold the two lone pairs. But having each lone pair of oxygen in an sp^2 orbital oriented away from the C=O bond lowers electron-electron repulsions.

FOLLOW-UP PROBLEMS

11.2B Caffeine has the structure shown. (a) What is the hybridization of each numbered C, N, and O atom? (b) How many σ and π bonds are present in caffeine?

SOME SIMILAR PROBLEMS 11.21–11.24, 11.46, 11.47, 11.56

Orbital Overlap and Rotation Within a Molecule

The type of overlap—end to end or side to side—affects rotation around the bond:

- **Sigma bond.** A σ bond allows free rotation because the extent of overlap is not affected. If you could hold one CH_3 group of ethane, the other CH_3 could spin without affecting the overlap of the $\text{C}-\text{C}$ σ bond (see Figure 11.10).
- **Pi bond.** A π bond restricts rotation because p orbitals must be parallel to each other to overlap most effectively. Holding one CH_2 group in ethylene and trying to spin the other decreases the side-to-side overlap and breaks the π bond. For this reason, distinct *cis* and *trans* structures exist for compounds such as 1,2-dichloroethylene (Section 10.3). As Figure 11.14 shows, the π bond allows two different arrangements of atoms around the C atoms, which has a major effect on molecular polarity (Section 10.3). Rotation around a triple bond is not meaningful: each triple-bonded C atom is bonded to one other group in a linear arrangement, so there can be no difference in the relative positions of attached groups.

Figure 11.14 Restricted rotation around a π bond. *Cis*- and *trans*-1,2-dichloroethylene are different molecules because the π bond restricts rotation.

Summary of Section 11.2

- › End-to-end overlap of atomic orbitals forms a σ bond, which allows free rotation of the bonded parts of the molecule.
- › A multiple bond consists of a σ bond and either one π bond (double bond) or two π bonds (triple bond). Multiple bonds have greater electron density between the nuclei than single bonds do and, thus, higher bond energies.
- › Side-to-side overlap of orbitals in a π bond restricts rotation.

11.3 MOLECULAR ORBITAL (MO) THEORY AND ELECTRON DELOCALIZATION

Scientists choose the model that best answers the question they are posing: VSEPR theory for one about molecular shape, or VB theory for one about orbital overlap. But neither model adequately explains magnetic and spectral properties, and both understate the importance of electron delocalization. To deal with these phenomena, which involve molecular energy levels, chemists apply **molecular orbital (MO) theory**. The MO model is a quantum-mechanical treatment for molecules similar to the one for atoms (Chapter 8): just as an atom has atomic orbitals (AOs) of given energies and shapes that are occupied by the atom's electrons, a molecule has **molecular orbitals (MOs)** of given energies and shapes that are occupied by the molecule's electrons.

There is a key distinction between VB and MO theories:

- VB theory pictures a molecule as a group of atoms bonded through overlapping of valence-shell atomic and/or hybrid orbitals occupied by *localized* electrons.
- MO theory pictures a molecule as a collection of nuclei with orbitals that extend over the whole molecule and are occupied by *delocalized* electrons.

Despite its usefulness, MO theory has the drawback that MOs are more difficult to visualize than the shapes of VSEPR theory or the hybrid AOs of VB theory.

The Central Themes of MO Theory

We will use H_2 and other simple species to highlight several key ideas of MO theory: how MOs form, what their energies and shapes are, and how they fill with electrons.

Formation of Molecular Orbitals Atomic orbitals (AOs, atomic wave functions) combine to form molecular orbitals (MOs, molecular wave functions). When two H nuclei lie near each other, the AOs overlap and combine in two ways:

- *Adding the wave functions together.* This combination forms a **bonding MO**, which has a *region of high electron density between the nuclei*. Additive overlap is analogous to light waves reinforcing each other, which makes the amplitude higher and the light brighter. For electron waves, the overlap *increases* the probability that the electrons are between the nuclei (Figure 11.15A).
- *Subtracting the wave functions from each other.* This combination forms an **antibonding MO**, which has a *node, a region of zero electron density, between the nuclei* (Figure 11.15B). Subtractive overlap is analogous to light waves canceling each other, causing the light to disappear. With electron waves, subtractive overlap means the probability that the electrons lie between the nuclei *decreases* to zero.

The two possible combinations for hydrogen atoms H_A and H_B are

AO of H_A + AO of H_B = bonding MO of H_2 (more e^- density between nuclei)

AO of H_A - AO of H_B = antibonding MO of H_2 (less e^- density between nuclei)

Notice that *the number of AOs combined always equals the number of MOs formed*: two H atomic orbitals combine to form two H_2 molecular orbitals, one bonding MO and one antibonding MO.

Shape and Energy of H_2 Molecular Orbitals Bonding and antibonding MOs have different shapes and energies. Figure 11.16 shows these orbitals for H_2 :

- **Bonding MO.** A bonding MO is *lower in energy* than the AOs that form it. Because the electron density is spread mostly *between* the nuclei, nuclear repulsions decrease while nucleus-electron attractions increase. Moreover, two electrons in this MO can delocalize their charges over a larger volume than they could in nearby, separate AOs, which lowers electron repulsions. Because of these electrostatic effects, when electrons occupy this MO, the H_2 molecule is *more stable* than the separate H atoms.
- **Antibonding MO.** An antibonding MO is *higher in energy* than the AOs that form it. With most of the electron density *outside* the internuclear region and a *node between the nuclei*, nuclear repulsions increase. Therefore, when electrons occupy this MO, the H_2 molecule is *less stable* than the separate H atoms.

Figure 11.15 An analogy between light waves and atomic wave functions.

Figure 11.16 Contours and energies of H_2 bonding and antibonding MOs.

Both the bonding and antibonding MOs of H_2 are **sigma (σ) MOs** because they are cylindrically symmetrical about an imaginary line between the nuclei (similar to the σ bonds discussed in Section 11.2):

- The bonding MO is denoted by σ_{1s} , that is, a σ MO derived from $1s$ AOs.
- Antibonding orbitals are denoted with a superscript star: the antibonding MO derived from $1s$ AOs is σ_{1s}^* (spoken “sigma, one ess, star”).

For AOs to interact enough to form MOs, they must be similar in *energy* and *orientation*. The $1s$ orbitals of two H atoms have identical energy and orientation, so they interact strongly. We’ll revisit this requirement for molecules composed of many-electron atoms.

Electrons in Molecular Orbitals Several aspects of MO theory—filling of MOs, energy-level diagrams, electron configuration, and bond order—relate to earlier ideas:

1. *Filling MOs with electrons.* Electrons enter MOs just as they do AOs:

- MOs are filled in order of increasing energy (aufbau principle).
- An MO can hold a maximum of two electrons with opposite spins (Pauli exclusion principle).
- Orbitals of equal energy are half-filled, with electron spins parallel, before any of them are filled (Hund’s rule).

2. *MO energy-level diagrams.* A **molecular orbital (MO) diagram** shows the relative energy and number of electrons for each MO, as well as for the AOs from which they are formed. In the MO diagram for H_2 (Figure 11.17), two electrons, one from the AO of each H, fill the lower energy bonding MO, while the higher energy antibonding MO remains empty.

3. *Electron configuration.* Just as we can write the electron configuration for an atom, we can write one for a molecule. The symbol of each occupied MO is written in parentheses, with the number of electrons in it as a superscript outside: the electron configuration of H_2 is $(\sigma_{1s})^2$.

4. *Bond order.* In a Lewis structure, bond order is the number of electron pairs per atom-to-atom linkage. The **MO bond order** is the number of electrons in bonding MOs minus the number in antibonding MOs, multiplied by $\frac{1}{2}$:

$$\text{Bond order} = \frac{1}{2}[(\text{no. of } e^- \text{ in bonding MOs}) - (\text{no. of } e^- \text{ in antibonding MOs})] \quad (11.1)$$

Here are three key points about MO bond order:

- Bond order > 0 : the molecule is more stable than the separate atoms, so it *will* form. For H_2 , the bond order is $\frac{1}{2}(2 - 0) = 1$.
- Bond order $= 0$: the molecule is as stable as the separate atoms, so it will *not* form (occurs when equal numbers of electrons occupy bonding and antibonding MOs).
- In general, the *higher* the bond order, the *stronger* the bond is.

Do He_2^+ and He_2 Exist? One of the early triumphs of MO theory was its ability to *predict* the existence of He_2^+ , the helium molecule-ion, which consists of two He nuclei and three electrons. Let’s use MO diagrams to see why He_2^+ exists but He_2 doesn’t:

- In He_2^+ , the $1s$ AOs form MOs (Figure 11.18A). The three electrons in the ion are distributed as a pair in the σ_{1s} MO and a lone electron in the σ_{1s}^* MO. The bond order is $\frac{1}{2}(2 - 1) = \frac{1}{2}$. Thus, He_2^+ has a relatively weak bond, but it should exist. Indeed, this species is observed frequently when He atoms collide with He^+ ions. Its electron configuration is $(\sigma_{1s})^2 (\sigma_{1s}^*)^1$.
- In He_2 , with two electrons in the σ_{1s} MO and two electrons in the σ_{1s}^* MO, both the bonding and antibonding orbitals are filled (Figure 11.18B). Stabilization from the electron pair in the bonding MO is canceled by destabilization from the electron pair in the antibonding MO. Because the bond order is zero [$\frac{1}{2}(2 - 2) = 0$], we predict, and experiment has so far confirmed, that a covalent He_2 molecule does not exist.

Figure 11.17 MO diagram for H_2 . The vertical placement of the boxes indicates relative energies. Orbital occupancy is shown with arrows and color (darker color = full occupancy, paler color = half-filled, no color = empty).

Figure 11.18 MO diagrams for He_2^+ and He_2 .

SAMPLE PROBLEM 11.3

Predicting Stability of Species Using MO Diagrams

Problem Use an MO diagram to find the bond order and predict whether H_2^+ exists. If it exists, write its electron configuration.

Plan Since the $1s$ AOs form the MOs, the MO diagram is similar to the one for H_2 . We find the number of electrons and distribute them one at a time to the MOs in order of increasing energy. We obtain the bond order with Equation 11.1 and write the electron configuration as described in the text.

Solution H_2 has two e^- , so H_2^+ has only one, which enters the bonding MO (*see diagram*). The bond order is $\frac{1}{2}(1 - 0) = \frac{1}{2}$, so we predict that H_2^+ exists. The electron configuration is $(\sigma_{1s})^1$.

Check The number of electrons in the MOs equals the number of electrons in the AOs.

Comment This species has been detected spectroscopically in the material around stars.

FOLLOW-UP PROBLEMS

11.3A Use an MO diagram to find the bond order and predict whether two H^- ions could form H_2^{2-} . If this species exists, write its electron configuration.

11.3B Use an MO diagram to find the bond order and predict whether two He^+ ions could form He_2^{2+} . If this species exists, write its electron configuration.

A SIMILAR PROBLEM 11.55

Homonuclear Diatomic Molecules of Period 2 Elements

Homonuclear diatomic molecules are composed of two identical atoms. In addition to H_2 from Period 1, you're familiar with N_2 , O_2 , and F_2 from Period 2 as the elemental forms under standard conditions. Others in Period 2— Li_2 , Be_2 , B_2 , C_2 , and Ne_2 —are observed, if at all, at high temperatures. We'll divide them into molecules from the s block, Groups 1 and 2, and those from the p block, Groups 13 through 18.

Bonding in the s-Block Homonuclear Diatomic Molecules Both Li and Be occur as metals under normal conditions, but MO theory can examine their stability as diatomic gases, dilithium (Li_2) and diberyllium (Be_2).

These atoms have electrons in inner ($1s$) and outer ($2s$) AOs, but we ignore the inner ones because, in general, *only outer (valence) AOs interact enough to form MOs*. Like those formed from $1s$ AOs, these $2s$ AOs form σ MOs, cylindrically symmetrical around the internuclear axis.

A Li_2 bond order = 1

B Be_2 bond order = 0

Figure 11.19 Bonding in s-block homonuclear diatomic molecules. Only outer (valence) AOs interact enough to form MOs.

- In Li_2 , the two valence electrons fill the bonding (σ_{2s}) MO, with opposing spins, leaving the antibonding (σ_{2s}^*) MO empty (Figure 11.19A). The bond order is $\frac{1}{2}(2 - 0) = 1$. In fact, Li_2 has been observed; the electron configuration is $(\sigma_{2s})^2$.
- In Be_2 , the four valence electrons fill the σ_{2s} and σ_{2s}^* MOs (Figure 11.19B), giving an orbital occupancy similar to that in He_2 . The bond order is $\frac{1}{2}(2 - 2) = 0$, and the ground state of Be_2 has never been observed.

Shape and Energy of MOs from Atomic p-Orbital Combinations In boron, atomic $2p$ orbitals are occupied. Recall that each atom has three mutually perpendicular $2p$ orbitals, p_x , p_y , and p_z (Figure 11.20A) and that p orbitals can overlap by two modes:

- End-to-end combination of the p_x orbitals of two atoms gives a pair of σ MOs, σ_{2p} and σ_{2p}^* (Figure 11.20B).
- Side-to-side combination of the p_y and p_z orbitals of two atoms gives two pairs of **pi (π) MOs**, π_{2p} and π_{2p}^* (Figure 11.20C).

Despite the different shapes, MOs derived from p orbitals are like those from s orbitals. Bonding MOs have most of the electron density *between* the nuclei, and antibonding MOs have most of it *outside* the internuclear region, with a node between the nuclei.

Figure 11.20 Shapes and energies of σ and π MOs from combinations of 2p atomic orbitals. **A**, The three 2p AOs. **B**, The p orbitals lying along the internuclear axis (designated p_x) overlap end to end and form σ_{2p} and σ_{2p}^* MOs. **C**, The p orbitals perpendicular to the internuclear axis (designated p_y and p_z) overlap side to side and form a total of four π MOs.

What can we conclude about the order of energy levels for the MO formed by the 2s and 2p AOs?

- MOs formed from 2s orbitals are *lower in energy* than MOs formed from 2p orbitals because 2s AOs are lower in energy than 2p AOs.
- Bonding MOs are *lower in energy* than antibonding MOs: σ_{2s} is lower in energy than σ_{2s}^* , σ_{2p} is lower in energy than σ_{2p}^* , and π_{2p} is lower than π_{2p}^* .

But what is the energy order of the σ_{2p} and π_{2p} MOs? Recall that only AOs of similar energy interact enough to form MOs. This fact leads to two energy orders, depending on whether s and p AOs mix to form MOs (Figure 11.21):

1. **Without mixing of s and p orbitals:** O_2 , F_2 , and Ne_2 . The order in Figure 11.21A assumes that s and p AOs are so different in energy that they do not interact; we say the orbitals do not *mix*. Lying at the right of Period 2, O, F, and Ne are relatively small. Thus, as electrons start to pair up in the half-filled 2p orbitals, strong repulsions raise the energy of the 2p orbitals high enough above the 2s orbitals to prevent orbital mixing. The energy order of the MOs derived from the 2p orbitals for O_2 , F_2 , and Ne_2 is

$$\sigma_{2p} < \pi_{2p} < \pi_{2p}^* < \sigma_{2p}^*$$

This order is expected when we consider that the end-to-end overlap of atomic p orbitals to form the σ_{2p} MO is more extensive than the side to side overlap that results in the π_{2p} MOs; it is not surprising that the σ_{2p} MO is lower in energy than the π_{2p} MO, and that the destabilizing effect of the σ_{2p}^* MO is greater than that of the π_{2p}^* MO.

Figure 11.21 Relative MO energy levels for Period 2 homonuclear diatomic molecules. (For clarity, the MOs affected by mixing are shown in purple.)

2. **With mixing of s and p orbitals:** B₂, C₂, and N₂. B, C, and N atoms are relatively large, with 2p AOs only half-filled, so repulsions are weaker. As a result, orbital energies are close enough for some mixing to occur between the 2s of one atom and the end-on 2p of the other. The effect of this mixing is to *lower* the energy of the σ_{2s} and σ_{2s}^* MOs and *raise* the energy of the σ_{2p} and σ_{2p}^* MOs; the π MOs are not affected. The MO diagram for B₂, C₂, and N₂ reflects this mixing (Figure 11.21B) that results in a reversal in energy order of the σ_{2p} and π_{2p} MOs:

$$\pi_{2p} < \sigma_{2p} < \pi_{2p}^* < \sigma_{2p}^*$$

Bonding in the p-Block Homonuclear Diatomic Molecules Figure 11.22 shows the MOs, electron occupancy, and some properties of B₂ through Ne₂. Note that

1. *Higher bond order correlates with greater bond energy and shorter bond length.*
2. Orbital occupancy correlates with magnetic properties. Recall from Chapter 8 that, if a substance has unpaired electrons, it is *paramagnetic* and, if all electrons are paired, the substance is *diamagnetic*; the same distinction applies to molecules. Let's examine the MO occupancy and some properties of these molecules:
 - B₂. The B₂ molecule has six outer electrons: four fill the σ_{2s} and σ_{2s}^* MOs. The remaining two electrons occupy the two π_{2p} MOs, one in each orbital, in keeping with Hund's rule. With four electrons in bonding MOs and two in antibonding MOs, the bond order of B₂ is $\frac{1}{2}(4 - 2) = 1$. As expected from the two lone electrons, B₂ is paramagnetic.
 - C₂. Two additional electrons in C₂ fill the two π_{2p} MOs. With two more bonding electrons than B₂, the bond order of C₂ is 2 and the bond is stronger and shorter. But, with all the electrons paired, C₂ is diamagnetic.
 - N₂. Two more electrons in N₂ fill the σ_{2p} MO, so the molecule is also diamagnetic. The bond order of 3 is consistent with the triple bond in the Lewis structure and with a stronger, shorter bond.
 - O₂. With this molecule, we see the power of MO theory over VB theory and others based on electrons in localized orbitals. It is impossible to write one Lewis structure consistent with the fact that O₂ has a double bond and is paramagnetic. We can write one structure with a double bond and paired electrons, and another with a single bond and two unpaired electrons:

Figure 11.22 MO occupancy and some properties of B₂ through Ne₂. Energy order and occupancy of MOs are above a bar graph showing bond energy and length, bond orders, magnetic properties, and outer (valence) electron configurations.

MO theory resolves this paradox beautifully: with eight electrons in bonding MOs and four in antibonding MOs, the bond order is $\frac{1}{2}(8 - 4) = 2$, and the molecule is paramagnetic because *one* electron occupies each of *two* π_{2p}^* MOs and these two electrons have unpaired (parallel) spins. A thin stream of liquid O₂ will remain suspended between the poles of a powerful magnet, as shown in the chapter-opening photo. As expected, the bond is weaker and longer than the one in N₂.

- F₂. Two more electrons in F₂ fill the π_{2p}^* orbitals, so it is diamagnetic. The bond has an order of 1 and is weaker and longer than the one in O₂. Note that this bond is shorter than the single bond in B₂ but only about half as strong. We might have expected it to be stronger because F is smaller than B. But 18 electrons in the smaller volume of F₂ cause greater repulsions than the 10 electrons in B₂, making the F₂ bond weaker.
- Ne₂. The final member of the Period 2 series doesn't exist for the same reason He₂ doesn't: all the MOs are filled, which gives a bond order of zero.

SAMPLE PROBLEM 11.4 Using MO Theory to Explain Bond Properties

Problem Explain the following data with diagrams showing the occupancy of MOs:

	N ₂	N ₂ ⁺	O ₂	O ₂ ⁺
Bond energy (kJ/mol)	945	841	498	623
Bond length (pm)	110	112	121	112

Plan The data show that removing an electron from each parent molecule has opposite effects: N₂⁺ has a weaker, longer bond than N₂, but O₂⁺ has a stronger, shorter bond than O₂. We determine the valence electrons in each species, draw the sequence of MO energy levels (showing orbital mixing in N₂ but not in O₂), and fill them with electrons. To explain the data, we calculate bond orders, which relate directly to bond energy and inversely to bond length.

Solution Determining the valence electrons:

N has 5 valence e^- , so N_2 has 10 and N_2^+ has 9.

O has 6 valence e^- , so O_2 has 12 and O_2^+ has 11.

Drawing and filling the MO diagrams:

Calculating bond orders:

$$\frac{1}{2}(8 - 2) = 3 \quad \frac{1}{2}(7 - 2) = 2.5 \quad \frac{1}{2}(8 - 4) = 2 \quad \frac{1}{2}(8 - 3) = 2.5$$

Explaining the data:

- When N_2 becomes N_2^+ , a *bonding* electron is removed, so the bond order decreases. Thus, N_2^+ has a weaker, longer bond than N_2 .
- When O_2 becomes O_2^+ , an *antibonding* electron is removed, so the bond order increases. Thus, O_2^+ has a stronger, shorter bond than O_2 .

Check The answers make sense in terms of bond order, bond energy, and bond length. Check that the total number of bonding and antibonding electrons equals the total number of valence electrons for each species.

FOLLOW-UP PROBLEMS

11.4A Determine the bond orders for these other dinitrogen species: N_2^{2+} , N_2^{2-} , and N_2^- . List the species in order of decreasing bond energy and in order of decreasing bond length.

11.4B Determine the bond orders for the following difluorine species: F_2^{2-} , F_2^- , F_2 , F_2^+ , and F_2^{2+} . List the species that exist in order of increasing bond energy and in order of increasing bond length.

SOME SIMILAR PROBLEMS 11.36 and 11.37

Student Hot Spot

Student data indicate that you may struggle with drawing molecular orbital diagrams. Access the eBook to view an additional Learning Resource video on this topic.

Two Heteronuclear Diatomic Molecules: HF and NO

Heteronuclear diatomic molecules have asymmetric MO diagrams because the AOs of the *different* atoms have unequal energies. Atoms with greater effective nuclear charge (Z_{eff}) pull their electrons closer, so they have more stable (lower energy) AOs (Section 8.1) and higher EN values (Section 9.5). Let's examine the bonding in HF and NO.

Bonding in HF To form the MOs in HF, we decide which AOs will combine. The high Z_{eff} of F means that its electrons are held so tightly that the 1s, 2s, and 2p orbitals have lower energy than the 1s of H. Thus, it is the half-filled 2p orbital of F that interacts with the 1s of H through end-on overlap, which forms σ and σ^* MOs. The two filled 2p orbitals of F are called **nonbonding MOs**. Because they are not involved in bonding, they have the same energy as the isolated AOs (Figure 11.23A).

The bonding MO of HF is closer in energy to the AOs of F, so the F 2p orbital contributes more to the HF bond than the H 1s does. In polar covalent molecules,

bonding MOs are closer in energy to the AOs of the more electronegative atom. In effect, fluorine's greater electronegativity lowers the energy of the bonding MO and draws the bonding electrons closer.

Bonding in NO Nitrogen monoxide (nitric oxide) is highly reactive because of its lone electron. Two possible Lewis structures for NO, with formal charges (Section 10.1), are

Both structures show a double bond, but the *measured* bond energy suggests a bond order *higher* than 2. Moreover, it is not clear where the lone electron resides, although the lower formal charges for structure I suggest that it is on the N.

The MO diagram is asymmetric, with the AOs of the more electronegative O lower in energy (Figure 11.23B). When the 11 valence electrons fill the MOs of NO, the lone electron occupies one of the π_{2p}^* orbitals. Eight bonding and three antibonding electrons give a bond order of $\frac{1}{2}(8 - 3) = 2.5$, more in keeping with the data than either Lewis structure. Bonding electrons lie in MOs closer in energy to the AOs of the more electronegative O atom. The 2p orbitals of N contribute more to the orbital that holds the lone electron, so it spends more time closer to N. (This diagram shows the energy order *with* mixing of the 2s and 2p orbitals, as in Figure 11.21, but the result is the same as the order without mixing.)

Two Polyatomic Molecules: Benzene and Ozone

The orbital shapes and MO diagrams for polyatomic molecules are too complex for detailed treatment here. But we'll briefly discuss how the model eliminates the need for resonance forms and helps explain the effects of the absorption of energy.

Recall that we cannot draw one Lewis structure for either benzene or ozone, so we draw separate forms of a resonance hybrid. The VB model also uses resonance because it relies on *localized* bonds. In contrast, MO theory pictures a structure of delocalized σ and π MOs. Figure 11.24 shows the lowest energy π bonding MOs in benzene and ozone. The extended areas of electron density allow delocalization of one electron pair in the π bonding MO over the entire molecule, thus eliminating the need for separate resonance forms:

- In *benzene*, the upper and lower hexagonal lobes of this MO lie above and below the plane of the six C nuclei.
- In *ozone*, the two lobes of this MO extend over and under the three O nuclei.

Figure 11.24 The lowest energy π bonding MOs in benzene and ozone.

The full MO diagrams for these molecules help us rationalize how bonding electrons in O_3 become excited and occupy empty antibonding orbitals when the molecule absorbs UV radiation in the stratosphere, and why the UV spectrum of benzene has its characteristic absorption bands.

› Summary of Section 11.3

- › Molecular orbital (MO) theory treats a molecule as a collection of nuclei with MOs delocalized over the entire structure.
- › Atomic orbitals of comparable energy can be added or subtracted to obtain bonding or antibonding MOs, respectively.
- › Bonding MOs, whether σ or π , have most of the electron density between the nuclei and are lower in energy than the AOs that combine to form them; most of the electron density in antibonding MOs does not lie between the nuclei, so these MOs are higher in energy.
- › MOs are filled in order of their energy with paired electrons having opposite spins.
- › MO diagrams show energy levels and orbital occupancy. Diagrams for the Period 2 homonuclear diatomic molecules explain bond energy, bond length, and magnetic behavior.
- › In heteronuclear diatomic molecules, the more electronegative atom contributes more to the bonding MOs.
- › MO theory eliminates the need for resonance forms to depict polyatomic molecules.

CHAPTER REVIEW GUIDE

Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

Understand These Concepts

1. The main ideas of valence bond theory—orbital overlap, opposing electron spins, and hybridization—as a means of rationalizing molecular shapes (§11.1)
2. How orbitals mix to form hybrid orbitals with different spatial orientations (§11.1)
3. The distinction between end-to-end and side-to-side overlap and the origin of sigma (σ) and pi (π) bonds in simple molecules (§11.2)
4. How the two modes of orbital overlap lead to single, double, and triple bonds (§11.2)
5. Why π bonding restricts rotation around double bonds (§11.2)
6. The distinction between the localized bonding of VB theory and the delocalized bonding of MO theory (§11.3)
7. How addition or subtraction of AOs forms bonding or antibonding MOs (§11.3)

8. The shapes of MOs formed from combinations of two s orbitals and combinations of two p orbitals (§11.3)
9. How MO bond order predicts the stability of molecular species (§11.3)
10. How MO theory explains the bonding and magnetic properties of homonuclear and heteronuclear diatomic molecules of Period 2 elements (§11.3)

Master These Skills

1. Using a partial orbital diagram and molecular shape to postulate the hybrid orbitals used by a central atom (SP 11.1)
2. Describing the types of orbitals and bonds in a molecule (SP 11.2)
3. Using MO diagrams to find the bond order and predict the stability of molecular species and writing the electron configuration of a species that exists (SP 11.3)
4. Explaining bond properties with MO theory (SP 11.4)

Key Terms

Page numbers appear in parentheses.

antibonding MO (450)	MO bond order (451)	nonbonding MO (456)	sp^2 hybrid orbital (440)
bonding MO (450)	molecular orbital (MO) (449)	pi (π) bond (446)	sp^3 hybrid orbital (441)
homonuclear diatomic molecule (452)	molecular orbital (MO) diagram (451)	pi (π) MO (452)	sp^3d hybrid orbital (442)
hybrid orbital (438)	molecular orbital (MO) theory (449)	sigma (σ) bond (446)	sp^3d^2 hybrid orbital (442)
hybridization (438)		sigma (σ) MO (451)	valence bond (VB) theory (437)
		sp hybrid orbital (440)	

Key Equations and Relationships

Page number appears in parentheses.

11.1 Calculating the MO bond order (451): Bond order = $\frac{1}{2}[(\text{no. of } e^- \text{ in bonding MOs}) - (\text{no. of } e^- \text{ in antibonding MOs})]$

CHAPTER PRACTICE TEST

The answers to the Practice Test problems are shown below and the full solutions can be found in the e-book.

- A π (pi) bond is the result of the
 - overlap of two s orbitals.
 - overlap of two p orbitals end-to-end.
 - overlap of an s and a p orbital.
 - side-to-side overlap of two s orbitals.
 - side-to-side overlap of two p orbitals.
- If a molecule is linear and the central atom exhibits sp^3d hybridization, how many unshared pairs of electrons are there on the central atom?
 - one
 - two
 - three
 - four
 - zero
- How many oxygen atoms in the molecular structure of aspirin shown below have sp^2 hybridization?

 - one
 - two
 - three
 - four
 - none of them
- How many σ bonds and π bonds are in the structure of aspirin shown in the preceding problem?
 - 21 σ bonds and 5 π bonds
 - 16 σ bonds and 5 π bonds
 - 16 σ bonds and 10 π bonds
 - 19 σ bonds and 4 π bonds
 - 21 σ bonds and 2 π bonds
- What is the hybridization of As in AsH_3 ?
 - sp
 - sp^2
 - sp^3
 - sp^3d
 - sp^3d^2
- What is the hybridization for the two carbon atoms in the following molecule?

 - sp and sp^2
 - sp^3 and sp
 - sp^2 and sp^3
 - Both are sp
 - Both are sp^2

- According to MO theory, what is the bond order for the species C_2^{2-} ? Is this species paramagnetic or diamagnetic?
 - 2, diamagnetic
 - 3, diamagnetic
 - 1, diamagnetic
 - 2, paramagnetic
 - 3, paramagnetic
 - 1, paramagnetic
- Which of the following species has/have a bond order of 1.5?

B_2^+ , B_2^- , C_2^+ , N_2^-

B_2^+ and C_2^+

B_2^+ and N_2^-

C_2^+ and N_2^-

B_2^- and C_2^+
- Which arrangement shows the species in order of decreasing bond length according to MO theory?

Li_2 , Li_2^+ , Li_2^-

$Li_2 = Li_2^+ > Li_2^-$

$Li_2 > Li_2^+ > Li_2^-$

$Li_2^+ > Li_2 = Li_2^-$

$Li_2 > Li_2^- = Li_2^+$
- Which partial orbital diagram correctly shows the hybrid orbitals and electron distribution of the O atom in the molecule OF_2 ?

a

b

c

d

Answers: 1. e; 2. c; 3. b; 4. a; 5. c; 6. b; 7. b; 8. d; 9. a; 10. b

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

11.1A (a) The central Be atom has two electron groups (two bonds); the electron-group arrangement and the molecular shape are linear, so Be is sp hybridized:

(b) The central Si atom has four electron groups (four bonds); the electron-group arrangement and the molecular shape are tetrahedral, so Si is sp^3 hybridized:

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS (continued)

(c) The central Xe atom has six electron groups (four bonds and two lone pairs); the electron-group arrangement is octahedral and the molecular shape is square planar, so Xe is sp^3d^2 hybridized:

11.1B (a) The central Al atom has three electron groups (three bonds); the electron-group arrangement is trigonal planar and the molecular shape is trigonal planar, so Al is sp^2 hybridized:

(b) The central P atom has four electron groups (three bonds and one lone pair); the electron-group arrangement is tetrahedral and the molecular shape is trigonal pyramidal, so P is sp^3 hybridized:

(c) The central Kr atom has five electron groups (two bonds and three lone pairs); the electron-group arrangement is trigonal bipyramidal and the molecular shape is linear, so Kr is sp^3d hybridized:

11.2A (a) $H-C\equiv N$:

HCN is linear (C has two electron groups), so C is sp hybridized. N is also sp hybridized. One sp of C overlaps the $1s$ of H to form a σ bond. The other sp of C overlaps one sp of N to form a σ bond. The other sp of N holds a lone pair. Two unhybridized p orbitals of N and two of C overlap to form two π bonds.

(b)

The C and O are sp^2 hybridized, and each N is sp^3 hybridized. The sp^3 orbitals of each N form three σ bonds, two with the $1s$ of two H atoms and one with an sp^2 of the C. A lone pair fills the fourth sp^3 of each N. The third sp^2 of the C forms a σ bond to one sp^2 of the O, and lone pairs fill the other sp^2 orbitals of the O. Unhybridized p orbitals on C and O form a π bond.

11.2B (a) C_1 : three electron groups: sp^2 ; C_2 : four electron groups: sp^3

N_3 : four electron groups: sp^3 ; N_4 : three electron groups: sp^2

O_5 : three electron groups: sp^2

(b) 25 σ bonds; four π bonds

11.3A Each H^- ion has two electrons, so H_2^{2-} has four electrons. Two electrons are in the σ_{1s} MO and two electrons are in the σ_{1s}^* MO. Does not exist: bond order = $\frac{1}{2}(2 - 2) = 0$.

11.3B Each He^+ ion has one electron, so He_2^{2+} has two electrons. Both electrons are in the σ_{1s} MO. Does exist: bond order = $\frac{1}{2}(2 - 0) = 1$; $(\sigma_{1s})^2$.

11.4A Bond orders: $\text{N}_2^{2+} = 2$; $\text{N}_2^- = 2.5$; $\text{N}_2^{2-} = 2$

Bond energy: $\text{N}_2^- > \text{N}_2^{2+} = \text{N}_2^{2-}$

Bond length: $\text{N}_2^{2+} = \text{N}_2^{2-} > \text{N}_2^-$

11.4B Bond orders: $\text{F}_2^{2-} = 0$; $\text{F}_2^- = 0.5$; $\text{F}_2 = 1$; $\text{F}_2^+ = 1.5$; $\text{F}_2^{2+} = 2$

Bond energy: F_2^{2-} does not exist; $\text{F}_2^- < \text{F}_2 < \text{F}_2^+ < \text{F}_2^{2+}$

Bond length: $\text{F}_2^{2+} < \text{F}_2^+ < \text{F}_2 < \text{F}_2^-$; F_2^{2-} does not exist

PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

Valence Bond (VB) Theory and Orbital Hybridization (Sample Problem 11.1)

Concept Review Questions

11.1 What type of central-atom orbital hybridization corresponds to each electron-group arrangement: (a) trigonal planar; (b) octahedral; (c) linear; (d) tetrahedral; (e) trigonal bipyramidal?

11.2 What is the orbital hybridization of a central atom that has one lone pair and bonds to: (a) two other atoms; (b) three other atoms; (c) four other atoms; (d) five other atoms?

11.3 How do carbon and silicon differ with regard to the *types* of orbitals available for hybridization? Explain.

11.4 How many hybrid orbitals form when four atomic orbitals of a central atom mix? Explain.

Skill-Building Exercises (grouped in similar pairs)

11.5 Give the number and type of hybrid orbital that forms when each set of atomic orbitals mixes:

(a) two *d*, one *s*, and three *p* (b) three *p* and one *s*

11.6 Give the number and type of hybrid orbital that forms when each set of atomic orbitals mixes:

(a) one *p* and one *s* (b) three *p*, one *d*, and one *s*

11.7 What is the hybridization of nitrogen in each of the following: (a) NO ; (b) NO_2 ; (c) NO_2^- ?

11.8 What is the hybridization of carbon in each of the following: (a) CO_3^{2-} ; (b) $\text{C}_2\text{O}_4^{2-}$; (c) NCO^- ?

11.9 What is the hybridization of chlorine in each of the following: (a) ClO_2 ; (b) ClO_3^- ; (c) ClO_4^- ?

11.10 What is the hybridization of bromine in each of the following: (a) BrF_3 ; (b) BrO_2^- ; (c) BrF_5 ?

11.11 Which types of atomic orbitals of the central atom mix to form hybrid orbitals in (a) SiClH_3 ; (b) CS_2 ; (c) SCl_3F ; (d) NF_3 ?

11.12 Which types of atomic orbitals of the central atom mix to form hybrid orbitals in (a) Cl_2O ; (b) BrCl_3 ; (c) PF_5 ; (d) SO_3^{2-} ?

11.13 Phosphine (PH_3) reacts with borane (BH_3) as follows:

(a) Which of the accompanying illustrations depicts the change, if any, in the orbital hybridization of P during this reaction? (b) Which depicts the change, if any, in the orbital hybridization of B?

11.14 The illustrations below depict differences in orbital hybridization of some tellurium (Te) fluorides. (a) Which depicts the difference, if any, between TeF_6 (left) and TeF_5^- (right)? (b) Which depicts the difference, if any, between TeF_4 (left) and TeF_6 (right)?

11.15 Use partial orbital diagrams to show how the atomic orbitals of the central atom lead to hybrid orbitals in (a) GeCl_4 ; (b) BCl_3 ; (c) CH_3^+ .

11.16 Use partial orbital diagrams to show how the atomic orbitals of the central atom lead to hybrid orbitals in (a) BF_4^- ; (b) PO_4^{3-} ; (c) SO_3 .

11.17 Use partial orbital diagrams to show how the atomic orbitals of the central atom lead to hybrid orbitals in (a) SeCl_2 ; (b) H_3O^+ ; (c) IF_4^- .

11.18 Use partial orbital diagrams to show how the atomic orbitals of the central atom lead to hybrid orbitals in (a) AsCl_3 ; (b) SnCl_2 ; (c) PF_6^- .

Problems in Context

11.19 Methyl isocyanate, $\text{CH}_3-\text{N}=\text{C}=\ddot{\text{O}}:$, is an intermediate in the manufacture of many pesticides. In 1984, a leak from a manufacturing plant resulted in the death of more than 2000 people in Bhopal, India. What are the hybridizations of the N atom and the two C atoms in methyl isocyanate? Sketch the molecular shape.

Modes of Orbital Overlap and the Types of Covalent Bonds

(Sample Problem 11.2)

Concept Review Questions

- 11.20** Are these statements true or false? Correct any false ones.
- Two σ bonds constitute a double bond.
 - A triple bond consists of one π bond and two σ bonds.
 - Bonds formed from atomic s orbitals are always σ bonds.
 - A π bond restricts rotation about the σ -bond axis.
 - A π bond consists of two pairs of electrons.
 - End-to-end overlap results in a bond with electron density above and below the bond axis.

Skill-Building Exercises (grouped in similar pairs)

11.21 Identify the hybrid orbitals used by the central atom and the type(s) of bonds formed in (a) NO_3^- ; (b) CS_2 ; (c) CH_2O .

11.22 Identify the hybrid orbitals used by the central atom and the type(s) of bonds formed in (a) O_3 ; (b) I_3^- ; (c) COCl_2 (C is central).

11.23 Identify the hybrid orbitals used by the central atom(s) and the type(s) of bonds formed in (a) FNO ; (b) C_2F_4 ; (c) $(\text{CN})_2$.

11.24 Identify the hybrid orbitals used by the central atom(s) and the type(s) of bonds formed in (a) N_3^- ; (b) $\text{CH}_3\text{C}\equiv\text{CH}$; (c) SO_2 .

Problem in Context

11.25 2-Butene ($\text{CH}_3\text{CH}=\text{CHCH}_3$) is a starting material in the manufacture of lubricating oils and many other compounds. Draw two different structures for 2-butene, indicating the σ and π bonds in each.

Molecular Orbital (MO) Theory and Electron Delocalization

(Sample Problems 11.3 and 11.4)

Concept Review Questions

11.26 Two p orbitals from one atom and two p orbitals from another atom are combined to form molecular orbitals for the joined atoms. How many MOs will result from this combination? Explain.

11.27 Certain atomic orbitals on two atoms were combined to form the following MOs. Name the atomic orbitals used and the MOs formed, and explain which MO has higher energy:

11.28 How do the bonding and antibonding MOs formed from a given pair of AOs compare to each other with respect to (a) energy; (b) presence of nodes; (c) internuclear electron density?

11.29 Antibonding MOs always have at least one node. Can a bonding MO have a node? If so, draw an example.

Skill-Building Exercises (grouped in similar pairs)

11.30 How many electrons does it take to fill (a) a σ bonding MO; (b) a π antibonding MO; (c) the MOs formed from combination of the $1s$ orbitals of two atoms?

11.31 How many electrons does it take to fill (a) the MOs formed from combination of the $2p$ orbitals of two atoms; (b) a σ_{2p}^* MO; (c) the MOs formed from combination of the $2s$ orbitals of two atoms?

11.32 The molecular orbitals depicted are derived from $2p$ atomic orbitals in F_2^+ . (a) Give the orbital designations. (b) Which is occupied by at least one electron in F_2^+ ? (c) Which is occupied by only one electron in F_2^+ ?

11.33 The molecular orbitals depicted below are derived from $n = 2$ atomic orbitals. (a) Give the orbital designations. (b) Which is highest in energy? (c) Lowest in energy? (d) Rank the MOs in order of increasing energy for B_2 .

11.34 Use an MO diagram and the bond order you obtain from it to answer these questions: (a) Is Be_2^+ stable? (b) Is Be_2^+ diamagnetic? (c) What is the outer (valence) electron configuration of Be_2^+ ?

11.35 Use an MO diagram and the bond order you obtain from it to answer these questions: (a) Is O_2^- stable? (b) Is O_2^- paramagnetic? (c) What is the outer (valence) electron configuration of O_2^- ?

11.36 Use MO diagrams to rank C_2^- , C_2 , and C_2^+ in order of (a) increasing bond energy; (b) increasing bond length.

11.37 Use MO diagrams to rank B_2^+ , B_2 , and B_2^- in order of (a) decreasing bond energy; (b) decreasing bond length.

Comprehensive Problems

11.38 Predict the shape, state the hybridization of the central atom, and give the ideal bond angle(s) and any expected deviations for: (a) BrO_3^- (b) $AsCl_4^-$ (c) SeO_4^{2-} (d) BiF_5^+ (e) SbF_4^+ (f) AlF_6^{3-} (g) IF_4^+

11.39 Butadiene (*right*) is a colorless gas used to make synthetic rubber and many other compounds. (a) How many σ bonds and π bonds does the molecule have? (b) Are *cis-trans* arrangements about the double bonds possible? Explain.

11.40 Epinephrine (or adrenaline; *below*) is a naturally occurring hormone that is also manufactured commercially for use as a heart stimulant, a nasal decongestant, and a glaucoma treatment.

(a) What is the hybridization of each C, O, and N atom? (b) How many σ bonds does the molecule have? (c) How many π electrons are delocalized in the ring?

11.41 Use partial orbital diagrams to show how the atomic orbitals of the central atom lead to the hybrid orbitals in: (a) IF_2^- (b) ICl_3 (c) $XeOF_4$ (d) BHF_2

11.42 Isoniazid (*below*) is an antibacterial agent that is very useful in treating many common strains of tuberculosis.

(a) How many σ bonds are in the molecule? (b) What is the hybridization of each C and N atom?

11.43 Hydrazine, N_2H_4 , and carbon disulfide, CS_2 , react to form a cyclic molecule (*below*). (a) Draw Lewis structures for N_2H_4 and CS_2 . (b) How do electron-group arrangement, molecular shape, and hybridization of N change when N_2H_4 reacts to form the product? (c) How do electron-group arrangement, molecular shape, and hybridization of C change when CS_2 reacts to form the product?

11.44 In each of the following equations, what hybridization change, if any, occurs for the underlined atom?

- (a) $\underline{B}F_3 + NaF \rightarrow Na^+ \underline{B}F_4^-$
 (b) $\underline{P}Cl_3 + Cl_2 \rightarrow PCl_5$
 (c) $\underline{H}C \equiv CH + H_2 \rightarrow H_2 \underline{C} = CH_2$
 (d) $\underline{Si}F_4 + 2F^- \rightarrow \underline{Si}F_6^{2-}$
 (e) $\underline{S}O_2 + \frac{1}{2}O_2 \rightarrow SO_3$

11.45 The ionosphere lies about 100 km above Earth's surface. This layer of the atmosphere consists mostly of NO , O_2 , and N_2 , and photoionization creates NO^+ , O_2^+ , and N_2^+ . (a) Use MO theory to compare the bond orders of the molecules and ions. (b) Does the magnetic behavior of each species change when its ion forms?

11.46 Glyphosate (*below*) is a common herbicide that is relatively harmless to animals but deadly to most plants. Describe the shape around and the hybridization of the P, N, and three numbered C atoms.

11.47 Tryptophan is one of the amino acids found in proteins:

(a) What is the hybridization of each of the numbered C, N, and O atoms? (b) How many σ bonds are present in tryptophan? (c) Predict the bond angles at points a, b, and c.

11.48 Some species consisting of just two oxygen atoms are the oxygen molecule, O_2 ; the peroxide ion, O_2^{2-} ; the superoxide ion, O_2^- ; and the dioxygenyl ion, O_2^+ . Draw an MO diagram for each, rank the species in order of increasing bond length, and find the number of unpaired electrons in each.

11.49 Molecular nitrogen, carbon monoxide, and cyanide ion are isoelectronic. (a) Draw an MO diagram for each. (b) CO and CN^- are toxic. What property may explain why N_2 isn't?

11.50 Chemists have isolated an anticancer agent called *genistein* from tofu, which may explain the much lower incidence of cancer in populations where tofu is a dietary staple. A valid Lewis structure for genistein is

(a) Is the hybridization of each C in the right-hand ring the same? Explain. (b) Is the hybridization of the O atom in the center ring the same as that of the O atoms in the OH groups? Explain. (c) How many carbon-oxygen σ bonds are there? How many carbon-oxygen π bonds? (d) Do all the lone pairs on oxygens occupy the same type of hybrid orbital? Explain.

11.51 An organic chemist synthesizes the molecule below:

(a) Which of the orientations of hybrid orbitals shown below are present in the molecule? (b) Are there any present that are not shown below? If so, what are they? (c) How many of each type of hybrid orbital are present?

11.52 Simple proteins consist of amino acids linked together in a long chain; a small portion of such a chain is

Experiment shows that rotation about the C—N bond (indicated by the arrow) is somewhat restricted. Explain with resonance structures, and show the types of bonding involved.

11.53 Sulfur forms oxides, oxoanions, and halides. What is the hybridization of the central S in SO_2 , SO_3 , SO_3^{2-} , SCl_4 , SCl_6 , and S_2Cl_2 (atom sequence Cl—S—S—Cl)?

11.54 The compound 2,6-dimethylpyrazine (*below*) gives chocolate its odor and is used in flavorings. (a) Which atomic orbitals mix to form the hybrid orbitals of N? (b) In what type of hybrid orbital do the lone pairs of N reside? (c) Is C in CH_3 hybridized the same as any C in the ring? Explain.

11.55 Use an MO diagram to find the bond order and predict whether H_2^- exists.

11.56 Acetylsalicylic acid (aspirin), the most widely used medicine in the world, has the Lewis structure shown. (a) What is the hybridization of each C and each O atom?

(b) How many localized π bonds are present? (c) How many C atoms have a trigonal planar shape around them? A tetrahedral shape?

11.57 Linoleic acid is an essential fatty acid found in many vegetable oils, such as soy, peanut, and cottonseed. A key structural feature of the molecule is the *cis* orientation around its two double

bonds, where R_1 and R_2 represent two different groups that form the rest of the molecule.

(a) How many different compounds are possible, changing only the *cis-trans* arrangements around these two double bonds?

(b) How many are possible for a similar compound with three double bonds?

Concepts and Skills to Review Before You Study This Chapter

- › properties of gases, liquids, and solids (Section 5.1)
- › kinetic-molecular theory of gases (Section 5.5)
- › kinetic and potential energy (Section 6.1)
- › enthalpy change, heat capacity, and Hess's law (Sections 6.2, 6.3, and 6.5)
- › diffraction of light (Section 7.1)
- › Coulomb's law (Section 9.2)
- › chemical bonding models (Chapter 9)
- › molecular polarity (Section 10.3)
- › molecular orbitals in diatomic molecules (Section 11.3)

All the matter in and around us occurs in one or more of the three physical states—gas, liquid, or solid—and, under different conditions, many substances can occur in any of the states. Water is probably the most familiar substance that commonly appears in all three states of matter, as shown in the photo of a Yellowstone Park geyser in winter. Clouds of the gas phase, steam, fill the air around the river of liquid water and banks of snow, the solid phase. You and I inhale and exhale gaseous water, drink, swim in, and wash with liquid water, and shovel, slide on, and cool our drinks with solid water.

The three states were introduced in Chapter 1, and their properties were compared when we examined gases in Chapter 5. You saw there that the particles in gases are, on average, very far apart. Now, we examine liquids and solids, which are called *condensed states* because *their particles are very close together*.

IN THIS CHAPTER . . . We explore the interplay of forces that give rise to the three states of matter and their changes, with special attention to liquids and solids.

- › We describe the types and relative strengths of the intermolecular forces in pure substances.
- › We use kinetic-molecular theory to see how relative magnitudes of potential and kinetic energy account for the behavior of gases, liquids, and solids and how temperature is related to phase changes.
- › We calculate the heat associated with warming or cooling a phase and with a phase change.
- › We highlight the effects of temperature and pressure on phases and their changes with phase diagrams.
- › We see how intermolecular forces underlie the properties of liquids.
- › As a special case, we trace the unique and vital physical properties of water to the electron configurations of the atoms making up its molecules.
- › We discuss the properties of solids, emphasizing the relation between type of bonding and predominant intermolecular force, and we examine crystal structures and two of the methods used to study them.
- › We introduce key features of several kinds of advanced materials—semiconductors, liquid crystals, ceramics, polymers, and nanostructures.

12.1 TYPES OF INTERMOLECULAR FORCES

There are two categories of forces that determine the chemical and physical properties of matter such as water (Figure 12.1):

- **Intramolecular forces** are *bonding* forces that exist *within* each molecule. These forces are due to the attraction between cations and anions (ionic bonding), nuclei and electron pairs (covalent bonding), or metal cations and delocalized electrons (metallic bonding). The *chemical* behavior of water, for example, is determined by the strength of the covalent bonding forces that are broken when water reacts.

Figure 12.1 Intramolecular forces (bonds) *within* molecules and intermolecular forces *between* molecules.

- **Intermolecular** (nonbonding) **forces** (or, more generally, *interparticle forces*) exist *between* the molecules. These forces arise from the attraction between molecules with partial charges or between ions and molecules. The strengths of these forces determine the *physical* properties of a substance.

Relative Strength of Intramolecular and Intermolecular Forces

Intermolecular forces are generally much weaker than intramolecular forces. As an example, compare the energy required to break the covalent bond in water, 497 kJ/mol, with the energy required to convert liquid water to gaseous water vapor, 40.7 kJ/mol. Vaporizing water involves breaking intermolecular forces, not the covalent bonds.

Coulomb's law explains the relative strength of these forces:

- *Bonding forces are relatively strong* because larger charges are closer together.
- *Intermolecular forces are relatively weak* because smaller charges are farther apart.

To get an idea of the distances involved in bonding versus intermolecular forces, let's consider solid Cl_2 . When we measure the distances between two Cl nuclei, we obtain two different values (Figure 12.2A):

- **Bond length and covalent radius.** The shorter distance, called the *bond length*, is between *two bonded Cl atoms in the same molecule*. One-half this distance is the *covalent radius*.
- **Van der Waals distance and radius.** The longer distance is between *two nonbonded Cl atoms in adjacent molecules*. It is called the *van der Waals (VDW) distance*. At this distance, intermolecular attractions balance electron-cloud repulsions; thus, the VDW distance is as close as one Cl_2 molecule can approach another. The **van der Waals radius** is one-half the closest distance between nuclei of identical *nonbonded* atoms. The VDW radius of an atom is *always larger than its covalent radius*. Like covalent radii, VDW radii decrease across a period and increase down a group (Figure 12.2B).

As we discuss intermolecular forces (also called *van der Waals forces*), consult Table 12.1, which compares them with bonding forces. We will also compare the strengths of the different types of intermolecular forces by comparing the boiling points of substances. To boil a liquid, heat energy must be added to break

Figure 12.2 Covalent and van der Waals radii and their periodic trends. **A**, The van der Waals (VDW) radius is one-half the closest distance between nuclei of adjacent *nonbonded* atoms ($\frac{1}{2} \times \text{VDW distance}$). **B**, Like covalent radii (blue quarter-circles and numbers), VDW radii (red quarter-circles and numbers) increase down a group and decrease across a period.

Table 12.1 | Comparison of Bonding and Nonbonding (Intermolecular) Forces

Force	Model	Basis of Attraction	Energy (kJ/mol)	Example
Bonding				
Ionic		Cation–anion	400–4000	NaCl
Covalent		Nuclei–shared e ⁻ pair	150–1100	H—H
Metallic		Cations–delocalized electrons	75–1000	Fe
Nonbonding (Intermolecular)				
Ion-dipole		Ion charge–dipole charge	40–600	$\text{Na}^+ \cdots \text{O} \begin{array}{l} \text{H} \\ \text{H} \end{array}$
H bond		Polar bond to H–dipole charge (high EN of N, O, F)	10–40	$\begin{array}{c} \text{:}\ddot{\text{O}}\text{--H} \\ \\ \text{H} \end{array} \cdots \begin{array}{c} \text{H--}\ddot{\text{O}}\text{:} \\ \\ \text{H} \end{array}$
Dipole-dipole		Dipole charges	5–25	$\text{I--Cl} \cdots \text{I--Cl}$
Dispersion (London)		Polarizable e ⁻ clouds	0.05–40	$\text{F--F} \cdots \text{F--F}$

any intermolecular forces that attract particles to each other; the stronger the intermolecular forces, the more energy it takes to separate the particles from each other and the higher the boiling point.

Ion-Dipole Forces

When an ion and a nearby polar molecule (dipole) attract each other, an **ion-dipole force** results. This type of force is found in mixtures, not in pure substances. The most important example takes place when an ionic compound dissolves in water. As you'll see in Chapter 13, one main reason the oppositely charged ions become separated is because the attractions between the ions and the oppositely charged poles of the H₂O molecules are stronger than the attractions between the ions themselves.

Dipole-Dipole Forces

Recall that a polar molecule has an unequal distribution of charge that causes a partially positive charge on one end of the molecule and a partially negative charge on the other end. The attractive forces that occur between the positive end (*blue*) of one molecule and the negative end (*red*) of another are called **dipole-dipole forces** (Figure 12.3). The orientation is more orderly in a solid than in a liquid because the average kinetic energy of the molecules is lower.

Figure 12.3 Polar molecules and dipole-dipole forces. (Spaces between the molecules are exaggerated.)

Figure 12.4 Dipole moment and boiling point.

Some key points about dipole-dipole forces include

- Dipole-dipole forces only exist for polar molecules, not for nonpolar molecules.
- These forces depend on the magnitude of the molecular dipole moment. For compounds of similar molar mass, the greater the molecular dipole moment, the greater the dipole-dipole forces.
- The greater the dipole-dipole forces, the more energy it takes to separate the molecules, so the boiling point is higher. Methyl chloride, for instance, has a smaller dipole moment than acetaldehyde and boils at a lower temperature (Figure 12.4).
- Dipole-dipole forces between partial charges of polar molecules are not as strong as ion-dipole forces between the full charge of ions and partial charges of polar molecules.

The Hydrogen Bond

A special type of dipole-dipole force arises between molecules that have an *H* atom bonded to a small, highly electronegative atom with lone electron pairs, specifically *N*, *O*, or *F*. The $\text{H}-\text{N}$, $\text{H}-\text{O}$, and $\text{H}-\text{F}$ bonds are very polar. A **hydrogen bond (H bond)** forms when the partially positive H of one molecule is attracted to the partially negative lone pair on the N, O, or F of another molecule. Thus, the atom sequence of an H bond (dotted line) is $-\text{B}:\cdots\text{H}-\text{A}-$, where *A* and *B* are N, O, or F. Some examples are

The first two are found in pure samples of HF and NH_3 , respectively.

The small sizes of N, O, and F are essential to H bonding for two reasons:

1. The atoms are so electronegative that their covalently bonded H is highly positive.
2. The lone pair on the N, O, or F of the other molecule can come close to the H.

Hydrogen bonds are generally stronger than other dipole-dipole forces, since the very polar bond between H and N, O, or F results in much larger partial positive and negative charges than are found in molecules that do not exhibit hydrogen bonding.

The Significance of Hydrogen Bonding Hydrogen bonding has a profound impact in many systems. For example, Figure 12.5 shows the effect of H bonding on the boiling points of the binary hydrides of Groups 14 through 17. For reasons we'll discuss shortly, boiling points rise with molar mass, as the Group 14 hydrides show. However, the first member in each of the other groups— NH_3 , H_2O , and HF —deviates enormously from this expected trend. Within samples of these substances, the molecules form strong H bonds, so it takes more energy for the molecules to separate and enter the gas phase. For example, on the basis of molar mass alone, we would expect water to boil about 200°C lower than it actually does (*red dashed line*). (In Section 12.5, we'll discuss the effects that H bonds in water have in nature.)

The significance of hydrogen bonding in biological systems cannot be emphasized too strongly. In Chapter 15, you'll see that it is a key feature in the structure and function of the biological macromolecules. As such, it is responsible for the action of many *enzymes*—the proteins that speed metabolic reactions—and for the functioning of genes, not to mention the strength of wood and texture of cotton.

Figure 12.5 Hydrogen bonding and boiling point. NH_3 , H_2O , and HF have exceptionally high boiling points because they form H bonds.

SAMPLE PROBLEM 12.1

Drawing Hydrogen Bonds Between Molecules of a Substance

Problem Which of these substances exhibits H bonding? Draw examples of the H bonds between two molecules of each substance that does.

- (a) C_2H_6 (b) CH_3OH (c) $\text{CH}_3\text{C}(=\text{O})\text{NH}_2$

Plan If the molecule does *not* contain N, O, or F, it cannot form H bonds. If it contains any of these atoms covalently bonded to H, we draw two molecules in the $\text{—B:}\cdots\text{H—A—}$ pattern.

Solution (a) For C_2H_6 , No N, O, or F, so no H bonds can form.

(b) For CH_3OH . The H covalently bonded to the O in one molecule forms an H bond to the lone pair on the O of an adjacent molecule:

(c) For $\text{CH}_3\text{C}(=\text{O})\text{NH}_2$. Two of these molecules can form one H bond between an H bonded to N and the O, or they can form two such H bonds:

A third possibility (not shown) could be between an H attached to N in one molecule and the lone pair of N in another molecule.

Check The $\text{—B:}\cdots\text{H—A—}$ sequence (with A and B either N, O, or F) is present.

Comment Note that H covalently bonded to C *does not form H bonds* because carbon is not electronegative enough to make the C—H bond sufficiently polar.

Figure 12.6 Dispersion forces among nonpolar particles. **A**, When atoms are far apart, an instantaneous dipole in one atom (left) doesn't influence another. **B**, When atoms are close together, the instantaneous dipole in one atom induces a dipole in the other. **C**, The process occurs throughout the sample.

17	18

Increasing strength of dispersion forces

Figure 12.7 Molar mass and trends in boiling point.

FOLLOW-UP PROBLEMS

Brief Solutions for **all** Follow-up Problems appear at the end of the chapter.

12.1A Which of these substances exhibits H bonding? Draw one possible example of the H bond(s) between two molecules of each substance that does.

12.1B Which of these substances exhibits H bonding? Draw one possible example of the H bond(s) between two molecules of each substance that does.

SOME SIMILAR PROBLEMS 12.12 and 12.13

Dispersion (London) Forces

So far, we've discussed forces that depend on the existing charge of an ion or a polar molecule. But what forces cause nonpolar substances like octane, chlorine, and argon to condense and solidify?

The intermolecular force responsible for the condensed states of nonpolar substances is the **dispersion force** (or **London force**, for Fritz London, the physicist who explained its quantum-mechanical basis). Dispersion forces are present between all particles (atoms, ions, and molecules) because they result from the motion of electrons in atoms. Let's examine key aspects of this force:

1. **Origin.** Picture one atom in a sample of, say, argon gas. Over time, its "electron cloud" of 18 electrons is distributed uniformly, so the atom is nonpolar. But, at any instant, because electrons are in constant motion, a distortion in the atom's electron cloud may occur such that there are more electrons on one side of the nucleus than the other, which gives the atom an *instantaneous dipole*. When a pair of argon atoms is far apart, they don't influence each other, but, when close together, the *instantaneous dipole in one atom induces (or causes) a dipole in its neighbor*, and they attract each other. This process spreads to other atoms and throughout the sample. At low temperatures, these attractions keep the atoms together (Figure 12.6). Thus, dispersion forces are *instantaneous dipole-induced dipole forces*.

2. **Universal presence.** While they are the *only* force existing between nonpolar particles, dispersion forces contribute to the energy of attraction in all substances because they exist between *all* particles. In fact, except for the forces between small, highly polar molecules or between molecules forming H bonds, the *dispersion force is the dominant intermolecular force*. Calculations show, for example, that 85% of the attraction between HCl molecules is due to dispersion forces and only 15% to dipole-dipole forces. Even for water, 75% of the attraction comes from H bonds and 25% from dispersion forces.

3. **Relative strength.** The relative strength of dispersion forces depends on the **polarizability** of the particles, the ease with which the electron cloud of an atom can be distorted. Smaller particles are less polarizable than larger ones because their electrons are closer to the nucleus and therefore held more tightly. Thus, we observe the following trends:

- Polarizability *increases down a group* because atomic size increases and larger electron clouds are easier to distort.
- Polarizability *decreases across a period* because increasing Z_{eff} makes the atoms smaller and the electrons are held more tightly.

Therefore, dispersion forces are relatively weak for small particles, like H_2 and He, but stronger for larger particles, like I_2 and Xe.

Figure 12.8 Molecular shape, intermolecular contact, and boiling point.

Figure 12.9 Determining the intermolecular forces in a sample.

Polarizability depends on the number of electrons, which correlates closely with molar mass because heavier particles are either larger atoms or molecules with more atoms and, thus, more electrons. For this reason:

- as molar mass increases, dispersion forces increase in strength, and so do boiling points.

The relationship between molar mass and boiling points can be seen for the Group 14 hydrides in Figure 12.5 and for the halogens and the noble gases in Figure 12.7.

4. Effect of molecular shape. For a pair of nonpolar substances with the same molar mass, a molecular shape that has more area over which electron clouds can be distorted allows stronger attractions. For example, the two five-carbon alkanes, *n*-pentane and neopentane (2,2-dimethylpropane) have the same molecular formula (C_5H_{12}) but different structures and properties. *n*-Pentane is more cylindrical and neopentane more spherical (Figure 12.8). Thus, two *n*-pentane molecules make more contact than do two neopentane molecules, so dispersion forces act at more points, and *n*-pentane has a higher boiling point.

Figure 12.9 shows how to decide what intermolecular forces are present in a sample.

Student Hot Spot

Student data indicate that you may struggle with the identifying the type(s) of intermolecular forces in a substance. Access the eBook to view an additional Learning Resource video on this topic.

SAMPLE PROBLEM 12.2 | Identifying the Types of Intermolecular Forces

Problem For each substance, identify the key bonding and/or intermolecular force(s), and predict which substance of the pair has the higher boiling point:

(a) $MgCl_2$ or PCl_3

(b) CH_3NH_2 or CH_3F

(c) CH_3OH or CH_3CH_2OH

(d) Hexane ($CH_3CH_2CH_2CH_2CH_2CH_3$) or 2,2-dimethylbutane

Plan We examine the formulas and structures for key differences between members of the pair: Are ions present? Are molecules polar or nonpolar? Is N, O, or F bonded to H? Do the molecules have different masses or shapes?

To rank boiling points, we consult Figure 12.9 and Table 12.1. Remember that

- Bonding forces are stronger than intermolecular forces.
- Hydrogen bonding is a strong type of dipole-dipole force.
- Dispersion forces are decisive when the difference is molar mass or molecular shape.

Solution (a) MgCl_2 consists of Mg^{2+} and Cl^- ions held together by ionic bonding forces; PCl_3 , with a trigonal pyramidal geometry, consists of polar molecules, so intermolecular dipole-dipole forces are present. The forces in MgCl_2 are stronger, so it should have a higher boiling point.

(b) CH_3NH_2 and CH_3F both consist of polar molecules of about the same molar mass. CH_3NH_2 has N—H bonds, so it can form H bonds (see figure). CH_3F contains a C—F bond but no H—F bond, so dipole-dipole forces occur but not H bonds. Therefore, CH_3NH_2 should have the higher boiling point.

(c) CH_3OH and $\text{CH}_3\text{CH}_2\text{OH}$ molecules both contain an O—H bond, so they can form H bonds (see figure). $\text{CH}_3\text{CH}_2\text{OH}$ has an additional $-\text{CH}_2-$ group and thus a larger molar mass, which correlates with stronger dispersion forces; therefore, it should have a higher boiling point.

(d) Hexane and 2,2-dimethylbutane are nonpolar molecules of the same molar mass but different molecular shapes (see figure). Cylindrical hexane molecules make more intermolecular contact than more compact 2,2-dimethylbutane molecules do, so hexane should have stronger dispersion forces and a higher boiling point.

Check The actual boiling points show that our predictions are correct:

- (a) MgCl_2 (1412°C) and PCl_3 (76°C)
 (b) CH_3NH_2 (-6.3°C) and CH_3F (-78.4°C)
 (c) CH_3OH (64.7°C) and $\text{CH}_3\text{CH}_2\text{OH}$ (78.5°C)
 (d) Hexane (69°C) and 2,2-dimethylbutane (49.7°C)

Comment Dispersion forces are *always* present, but, in parts (a) and (b), they are much less significant than the other forces that occur.

FOLLOW-UP PROBLEMS

12.2A In each pair, identify the intermolecular forces present for each substance, and predict which substance has the *higher* boiling point:

- (a) CH_3Br or CH_3F (b) $\text{CH}_3\text{CH}_2\text{CH}_2\text{OH}$ or $\text{CH}_3\text{CH}_2\text{OCH}_3$ (c) C_2H_6 or C_3H_8

12.2B In each pair, identify the intermolecular forces present for each substance, and predict which substance has the *lower* boiling point:

- (a) CH_3CHO or $\text{CH}_3\text{CH}_2\text{OH}$ (b) SO_2 or CO_2

- (c) $\text{H}_2\text{N}-\text{C}(=\text{O})\text{CH}_2\text{CH}_3$ or $(\text{CH}_3)_2\text{N}-\text{C}(=\text{O})\text{CH}_3$

SOME SIMILAR PROBLEMS 12.8–12.11 and 12.18–12.23

Summary of Section 12.1

- The chemical behavior of a substance is determined by the bonding forces within molecules while the physical properties are determined by the intermolecular forces between molecules.
- The van der Waals radius determines the shortest distance over which intermolecular forces operate; it is always larger than the covalent radius.
- Intermolecular forces are much weaker than bonding (intramolecular) forces.
- Ion-dipole forces occur between ions and polar molecules.
- Dipole-dipole forces occur between oppositely charged poles on polar molecules.
- Hydrogen bonding, a special type of dipole-dipole force, occurs when H bonded to N, O, or F is attracted to the lone pair of N, O, or F in another molecule.
- Dispersion (London) forces are instantaneous dipole-induced dipole forces that occur among all particles and increase with number of electrons (molar mass). Molecular shape determines the extent of contact between molecules and can be a factor in the strength of dispersion forces.

12.2 AN OVERVIEW OF PHYSICAL STATES AND PHASE CHANGES

Each physical state is called a **phase**, a physically distinct, homogeneous part of a system. The water in a closed container is the liquid phase; the water vapor above the liquid is the gas phase; add some ice, and now we have the solid phase. In this section, we will examine the properties of each phase, as determined by the relative energies of the particles, and the transformation from one phase to another.

A Kinetic-Molecular View of the Three States

The interactions between the potential energy and the kinetic energy of the particles give rise to the properties of each phase:

1. The intramolecular and intermolecular forces discussed in Section 12.1 are electrostatic forces that determine the *potential energy* in a sample of matter.
2. The *kinetic energy* is the energy of motion of the particles in a substance and is proportional to the absolute temperature (Section 5.5); the greater the kinetic energy of the particles at a particular temperature, the greater their average speed.

The potential energy in the form of the intermolecular forces tends to draw particles in a substance together, while kinetic energy tends to spread them out. Whether a substance occurs as a gas, liquid, or solid depends on the interplay of the potential and kinetic energy. As we move from gas to liquid to solid, the potential energy (energy of attraction between particles) influence increases in importance while the kinetic energy (energy of motion) decreases in importance. This determines the macroscopic properties of the three phases of matter, summarized in Table 12.2.

Table 12.2 A Comparison of Gases, Liquids, and Solids		
Gas	Liquid	Solid
		
Kinetic energy dominates the potential energy of intermolecular forces. On average, gas particles are far apart (low density) and move randomly throughout the container. The large distance between gas particles means that a gas is highly compressible. Since the gas particles have freedom of motion, a gas fills its container, taking both the volume and shape of the container. A gas flows easily through another gas.	Intermolecular attractions between particles are strong enough to pull the particles closer together. Liquid particles touch each other (higher density) and have limited freedom of motion. The particles move randomly around each other. Liquids resist an applied force and thus compress only slightly. The particles still have enough kinetic energy to move randomly around each other, so a liquid conforms to the shape of its container, but it has a surface (it does not fill the container). A liquid does flow, but <i>much</i> more slowly than a gas.	Intermolecular forces clearly dominate the kinetic energy of the particles. The particles are fixed in position next to each other in a regular three-dimensional pattern; solids have relatively high density and very low freedom of motion; particles in a solid just jiggle in place. The particles are so close together that a solid compresses even less than a liquid. Since the particles have very little freedom of motion, a solid does not take the shape nor volume of its container. A solid does not flow significantly.

Types of Phase Changes and Their Enthalpies

The potential and kinetic energies in each phase explain **phase changes**, physical changes from one phase to another; the effect of temperature is also critical:

- As *temperature increases*, the average kinetic energy does too, so the particles move faster and overcome attractions more easily.
- As *temperature decreases*, the average kinetic energy does too, so particles move more slowly and attractions can pull them together more easily.

Pressure also affects phase changes, most dramatically when gases are involved and to a lesser extent with liquids. Each phase change is accompanied by an enthalpy change, ΔH , given in units of *kilojoules per mole* (measured at 1 atm and the temperature of the change). The enthalpy change is either exothermic or endothermic:

- **Exothermic changes.** As the particles of a gas attract each other into a liquid, and then become fixed in a solid, the system of particles *loses* energy, which is released as heat.
- **Endothermic changes.** Heat must be absorbed by the system to overcome the attractive forces that keep the particles fixed in place in a solid or near each other in a liquid.

Let's look at the various phase changes:

1. Solid to liquid, and vice versa.

- As the temperature increases, the particles in a solid gain kinetic energy and move out of their fixed positions into the liquid phase in a process called **melting**, or **fusion**. The accompanying enthalpy change is called the **heat** (or *enthalpy*) **of fusion** ($\Delta H_{\text{fus}}^\circ$). In the case of water

- As the temperature drops, the particles in a liquid move more slowly and become fixed in position in the solid phase in the process of **freezing** (for most substances, an increase in pressure supports freezing as well.) Freezing of a substance has an enthalpy change of the *same magnitude but opposite sign* as the heat of fusion:

In common speech, *freezing* implies low temperature because we think of water. But, for example, molten metals freeze (solidify) at much higher temperatures, which gives them many medical, industrial, and artistic applications, such as gold dental crowns, steel auto bodies, and bronze statues.

2. Liquid to gas, and vice versa.

- As the temperature increases further, the molecules in the liquid phase gain sufficient kinetic energy to separate from each other completely and form a gas in the process of **vaporization**. The enthalpy change is called the **heat** (or *enthalpy*) **of vaporization** ($\Delta H_{\text{vap}}^\circ$). For water,

Sweating has a cooling effect because heat from your body vaporizes the water (Figure 12.10A).

- As the temperature drops (and/or the pressure rises), the molecules in the gas phase move more slowly, come together, and form a liquid in the process of **condensation**, with an enthalpy change with the same magnitude but opposite sign of the heat of vaporization:

3. Solid to gas, and vice versa.

- Under certain conditions, as the temperature of a solid increases and the particles gain kinetic energy, they move directly to the gas phase in a process called **sublimation**. The enthalpy energy is called the **heat** (or *enthalpy*) **of sublimation** ($\Delta H_{\text{sub}}^\circ$). Since sublimation can be considered a combination of melting and

A Vaporization

B Deposition

Figure 12.10 Two familiar phase changes.

Source: (A) Jose Luis Pelaez Inc/Blend Images LLC; (B) dinadesign/Shutterstock

vaporizing steps, Hess's law (Section 6.5) says that the heat of sublimation equals the sum of the heats of fusion and vaporization; for water,

Freeze-dried foods are prepared by freezing the food and subliming the water. Solid CO_2 (dry ice) sublimates to gaseous CO_2 under ordinary conditions. Liquid CO_2 occurs only at pressures of 5.1 atm or greater.

- The opposite process, changing from a gas directly into a solid as the gas particles are cooled and lose energy is called **deposition**—ice crystals form on a cold window from the deposition of water vapor (Figure 12.10B):

Water behaves typically in that it takes much less energy to melt the solid than to vaporize the liquid (or sublime the solid): $\Delta H_{\text{fus}}^\circ < \Delta H_{\text{vap}}^\circ$. That is, it takes less energy to reduce the intermolecular forces enough for the molecules to move out of their fixed positions (melt a solid) than to separate them completely (vaporize a liquid) (Figure 12.11).

Figure 12.11 Heats of vaporization and fusion for several common substances.

Figure 12.12 summarizes the phase changes and their enthalpy changes:

- Freezing, condensation, and deposition are exothermic changes.
- Melting, vaporization, and sublimation are endothermic changes.

Figure 12.12 Phase changes and their enthalpy changes. Fusion (or melting), vaporization, and sublimation are endothermic changes (positive ΔH°), whereas freezing, condensation, and deposition are exothermic changes (negative ΔH°).

Summary of Section 12.2

- Because of the relative magnitudes of intermolecular forces (potential energy) and average speed (kinetic energy), the particles in a gas are far apart and moving randomly, those in a liquid are in contact and moving relative to each other, and those in a solid are in contact and in fixed positions. These molecular-level differences account for macroscopic differences in shape, compressibility, and ability to flow.
- When a solid becomes a liquid (melting, or fusion), a liquid becomes a gas (vaporization), or a solid becomes a gas (sublimation), energy is absorbed to overcome intermolecular forces and increase the average distance between particles. As particles come closer together in the reverse changes (freezing, condensation, and deposition), energy is released. Each phase change is associated with a given enthalpy change under specified conditions.

12.3 QUANTITATIVE ASPECTS OF PHASE CHANGES

Of course, many phase changes of water occur around you every day, accompanied by the release or absorption of heat. When it rains, water vapor has condensed to a liquid, which changes back to a gas as puddles dry up. In the spring, solid water melts and, in winter, it freezes again. And the same phase changes take place whenever you make a pot of tea or a tray of ice cubes. In this section, we quantify the heat involved in a phase change and examine the equilibrium nature of the process.

Heat Involved in Phase Changes

We apply a kinetic-molecular approach to phase changes with a **heating-cooling curve**, which shows the changes in temperature of a sample when heat is absorbed or released at a constant rate. Let's examine what happens when 2.50 mol of gaseous water in a closed container undergoes a change from 130°C to −40°C at a constant pressure of 1 atm. We'll divide this process into five heat-releasing (exothermic) stages (Figure 12.13).

Figure 12.13 A heating-cooling curve for the conversion of gaseous water to ice. A plot of temperature versus heat released as gaseous water changes to ice is shown, with a molecular-level depiction for each stage. The slopes of the lines in stages 1, 3, and 5 reflect the molar heat capacities of the phases. Although not drawn to scale, the line in stage 2 is longer than the line in stage 4 because $\Delta H_{\text{vap}}^{\circ}$ of water is greater than $\Delta H_{\text{fus}}^{\circ}$. A plot of temperature versus heat absorbed starting at −40°C would have the same steps but in reverse order.

Stage 1. Gaseous water cools. Water molecules zoom chaotically at a range of speeds, smashing into each other and the container walls. At the starting temperature, the most probable speed of the molecules, and thus their average kinetic energy (E_k), is high enough to overcome the potential energy (E_p) of attractions. As the temperature falls, the average E_k decreases and attractions become more important. The change is

The heat lost in the cooling process (q) is the product of the amount (number of moles, n) of water, the molar heat capacity of *gaseous* water, $C_{m(\text{water}, g)}$ ($\text{J/mol}\cdot\text{K}$ or $\text{J/mol}\cdot^\circ\text{C}$), and the temperature change during this step, ΔT ($T_{\text{final}} - T_{\text{initial}}$):

$$\begin{aligned} q &= n \times C_{m(\text{water}, g)} \times \Delta T = (2.50 \text{ mol})(33.1 \text{ J/mol}\cdot^\circ\text{C})(100^\circ\text{C} - 130^\circ\text{C}) \\ &= -2482 \text{ J} = -2.48 \text{ kJ} \end{aligned}$$

The negative sign indicates that heat is released. (For purposes of canceling, the units for molar heat capacity, C_m , include $^\circ\text{C}$ rather than K, but this doesn't affect the magnitude of C_m because 1°C and 1 K represent the same temperature increment.) Note that in Chapter 6, we used a similar equation to calculate q , but we used the mass of the sample instead of moles and we used specific heat capacity instead of molar heat capacity.

Stage 2. Gaseous water condenses. At the condensation point, intermolecular attractions cause the slowest of the molecules to aggregate into microdroplets and then a bulk liquid. Note that, during the phase change,

- The temperature of the sample, and thus its average E_k , is constant during the phase change from gas to liquid. At the same temperature, molecules move farther between collisions in a gas than in a liquid, but their *average* speed is the same.
- Releasing heat from the sample decreases the average E_p as the molecules approach and attract each other.

Thus, at 100°C , gaseous and liquid water have the same average E_k , but the liquid has lower average E_p . The change is

The heat is the amount (n) of water times the negative of the heat of vaporization ($-\Delta H_{\text{vap}}^\circ$):

$$q = n(-\Delta H_{\text{vap}}^\circ) = (2.50 \text{ mol})(-40.65 \text{ kJ/mol}) = -102 \text{ kJ}$$

This stage contributes the *greatest portion of the total heat released* because of the large decrease in E_p as the molecules become so much closer in the liquid than they were in the gas.

Stage 3. Liquid water cools. The molecules in the liquid state continue to lose heat, and the loss appears as a decrease in temperature, that is, as a decrease in the most probable molecular speed and, thus, the average E_k . The temperature decreases as long as the sample remains liquid. The change is

The heat depends on amount (n), the molar heat capacity of *liquid* water, and ΔT :

$$\begin{aligned} q &= n \times C_{m(\text{water}, l)} \times \Delta T = (2.50 \text{ mol})(75.3 \text{ J/mol}\cdot^\circ\text{C})(0^\circ\text{C} - 100^\circ\text{C}) \\ &= -18,825 \text{ J} = -18.8 \text{ kJ} \end{aligned}$$

Stage 4. Liquid water freezes. At 0°C , the sample loses E_p as increasing intermolecular attractions cause the molecules to align themselves into the crystalline structure of ice. Molecular motion continues only as random jiggling about fixed positions. As we saw during condensation, temperature and average E_k are constant during freezing. The change is

The heat is equal to n times the negative of the heat of fusion ($-\Delta H_{\text{fus}}^\circ$):

$$q = n(-\Delta H_{\text{fus}}^\circ) = (2.50 \text{ mol})(-6.01 \text{ kJ/mol}) = -15.0 \text{ kJ}$$

Stage 5. Solid water cools. With motion restricted to jiggling in place, further cooling merely reduces the average speed of this jiggling. The change is

The heat depends on n , the molar heat capacity of *solid* water, and ΔT :

$$q = n \times C_{\text{m(water, s)}} \times \Delta T = (2.50 \text{ mol})(37.6 \text{ J/mol}\cdot^\circ\text{C})(-40^\circ\text{C} - 0^\circ\text{C}) \\ = -3760 \text{ J} = -3.76 \text{ kJ}$$

According to Hess's law, the total heat released is the sum of the heats released for the individual stages:

$$\begin{aligned} \text{Total heat released} &= \text{Stage 1} + \text{Stage 2} + \text{Stage 3} + \text{Stage 4} + \text{Stage 5} \\ &\quad \text{(gas cooling)} \quad \text{(gas condensing)} \quad \text{(liquid cooling)} \quad \text{(liquid freezing)} \quad \text{(solid cooling)} \\ &= -2.48 \text{ kJ} + (-102 \text{ kJ}) + (-18.8 \text{ kJ}) + (-15.0 \text{ kJ}) + (-3.76 \text{ kJ}) \\ &= -142 \text{ kJ} \end{aligned}$$

Two key points stand out for this or any similar process, whether exothermic or endothermic:

- *Within a phase,* heat flow is accompanied by a *change in temperature*, which is associated with a change in average E_k , as *the most probable speed of the molecules changes*. The heat released or absorbed depends on the amount of substance, the molar heat capacity *for that phase*, and the change in temperature.
- *During a phase change,* heat flow occurs at a *constant temperature*, which is associated with a change in average E_p , as *the average distance between molecules changes*. Both phases are present and (as you'll see) are in equilibrium during the change. The heat released or absorbed depends on the amount of substance and the enthalpy change for that phase change.

Let's work a molecular-scene sample problem to make sure these ideas are clear.

Student Hot Spot

Student data indicate that you may struggle with the quantitative aspects of phase changes. Access the eBook to view an additional Learning Resource video on this topic.

SAMPLE PROBLEM 12.3

Finding the Heat of a Phase Change Depicted by Molecular Scenes

Problem The scenes below represent a phase change of water. Use values for molar heat capacities and heats of phase changes from the text discussion to find the heat (in kJ) released or absorbed when 24.8 g of H_2O undergoes this change.

Plan From the molecular scenes, values given in the text discussion, and the given mass (24.8 g) of water, we have to find the heat that accompanies this change. The scenes show a disorderly, condensed phase at 85.0°C changing to separate molecules at 117°C. Thus, the phase change they depict is vaporization, an endothermic process. The values for molar heat capacities and heats of phase changes are per mole, so we first convert the mass (g) of water to amount (mol). There are three stages: (1) heating the liquid from 85.0°C to 100.°C; (2) converting liquid water at 100.°C to gaseous water at 100.°C; and (3) heating the gas from 100.°C to 117°C (see figure). We add the values of q for these stages to obtain the total heat.

Solution Converting from mass (g) of H_2O to amount (mol):

$$\text{Amount (mol) of H}_2\text{O} = 24.8 \text{ g H}_2\text{O} \times \frac{1 \text{ mol}}{18.02 \text{ g H}_2\text{O}} = 1.38 \text{ mol}$$

Finding the heat accompanying stage 1, $\text{H}_2\text{O}(l)$ $[85.0^\circ\text{C}] \rightarrow \text{H}_2\text{O}(l)$ $[100.^\circ\text{C}]$:

$$q = n \times C_{m(\text{water}, l)} \times \Delta T = (1.38 \text{ mol})(75.3 \text{ J/mol}\cdot^\circ\text{C})(100.^\circ\text{C} - 85.0^\circ\text{C}) \\ = 1559 \text{ J} = 1.56 \text{ kJ}$$

Finding the heat accompanying stage 2, $\text{H}_2\text{O}(l)$ $[100.^\circ\text{C}] \rightarrow \text{H}_2\text{O}(g)$ $[100.^\circ\text{C}]$:

$$q = n(\Delta H_{\text{vap}}^\circ) = (1.38 \text{ mol})(40.65 \text{ kJ/mol}) = 56.1 \text{ kJ}$$

Finding the heat accompanying stage 3, $\text{H}_2\text{O}(g)$ $[100.^\circ\text{C}] \rightarrow \text{H}_2\text{O}(g)$ $[117^\circ\text{C}]$:

$$q = n \times C_{m(\text{water}, g)} \times \Delta T = (1.38 \text{ mol})(33.1 \text{ J/mol}\cdot^\circ\text{C})(117^\circ\text{C} - 100.^\circ\text{C}) \\ = 776.5 \text{ J} = 0.777 \text{ kJ}$$

Adding the three heats to find the total heat for the process:

$$\text{Total heat (kJ)} = 1.56 \text{ kJ} + 56.1 \text{ kJ} + 0.777 \text{ kJ} = \boxed{58.4 \text{ kJ}}$$

Check The heat should have a positive value because it is absorbed. Be sure to round to check each value of q ; for example, in stage 1, $1.38 \text{ mol} \times 75 \text{ J/mol}\cdot^\circ\text{C} \times 15^\circ\text{C} = 1550 \text{ J}$. Note that the phase change itself (stage 2) requires the most energy and, thus, dominates the final answer. The $\Delta H_{\text{vap}}^\circ$ units include kJ, whereas the molar heat capacity units include J, which is a thousandth as large.

FOLLOW-UP PROBLEMS

12.3A The scenes below represent a phase change of water. Use values for molar heat capacities and heats of phase changes from the text discussion to find the heat (in kJ) released or absorbed when 2.25 mol of H_2O undergoes this change.

12.3B The scenes below represent a phase change of bromine, Br_2 . Use the following data to find the heat (in kJ) released or absorbed when 47.94 g of bromine undergoes this change: $C_{m(\text{liquid})} = 75.7 \text{ J/mol}\cdot^\circ\text{C}$; $C_{m(\text{gas})} = 36.0 \text{ J/mol}\cdot^\circ\text{C}$; $\Delta H_{\text{fus}}^\circ = 10.6 \text{ kJ/mol}$; $\Delta H_{\text{vap}}^\circ = 29.6 \text{ kJ/mol}$; $\text{mp} = -7.25^\circ\text{C}$; $\text{bp} = 59.5^\circ\text{C}$.

SOME SIMILAR PROBLEMS 12.45 and 12.46

The Equilibrium Nature of Phase Changes

In everyday experience, phase changes take place in *open* containers—the outdoors, a pot on a stove, the freezer compartment of a refrigerator—so they are not reversible. But, in a *closed* container, *phase changes are reversible and reach equilibrium*, just as chemical changes do. In this discussion, we examine the three phase equilibria.

Liquid-Gas Equilibria Vaporization and condensation are familiar events. Let's see how these processes differ in open and closed systems of a liquid in a flask:

1. *Open system: nonequilibrium process.* Picture an *open* flask containing a pure liquid at constant temperature. Within their range of speeds, some molecules at the

Figure 12.14 Liquid-gas equilibrium.

A, Molecules leave the surface at a constant rate and the pressure rises. **B**, At equilibrium, the same number of molecules leave and enter the liquid in a given time. **C**, Pressure increases until, at equilibrium, it is constant.

surface have a high enough E_k to overcome attractions and vaporize. Nearby molecules fill the gap, and with heat supplied by the constant-temperature surroundings, the process continues until the entire liquid phase is gone.

2. *Closed system: equilibrium process.* Now picture a *closed* flask at constant temperature and assume a vacuum exists above a liquid in the flask (Figure 12.14A). Let's examine what occurs:

- Some molecules at the surface have a high enough E_k to *vaporize*; as molecules enter the vapor phase, the pressure increases.
- After a short time, molecules in the vapor collide with the surface, and the slower ones are attracted strongly enough to *condense*.
- At first, the rate of vaporization is greater than the rate of condensation, and the pressure continues to increase. With time, the number of molecules colliding with and entering the surface increases as the vapor becomes more populated; with this increase in the rate of condensation, the increase in pressure slows.
- Eventually, the rate of condensation equals the rate of vaporization, and from this time forward, *the pressure is constant* (Figure 12.14B).
- Now, molecules are entering and leaving the liquid at equal rates. The system has reached a state of *dynamic equilibrium*:

Figure 12.14C depicts the entire process graphically. The pressure exerted by the vapor in equilibrium with its liquid is called the **vapor pressure** of the liquid at that temperature.

The Effects of Temperature and Intermolecular Forces on Vapor Pressure The vapor pressure is affected by two factors—a change in temperature and a change in the gas itself, that is, in the type and/or strength of intermolecular forces:

1. *Effect of temperature.* Temperature has a major effect on vapor pressure because it changes the fraction of molecules moving fast enough to escape the liquid and, by the same token, the fraction moving slowly enough to be recaptured. In Figure 12.15, we see the familiar skewed bell-shaped curve of the distribution of molecular speeds (see also Figure 5.21). At the higher temperature, T_2 , more molecules have enough energy to leave the surface. Thus, in general, *the higher the temperature is, the higher the vapor pressure*:

2. *Effect of intermolecular forces.* At a given T , all substances have the same average E_k . Therefore, molecules with weaker intermolecular forces are held less tightly at the surface and vaporize more easily. In general, *the weaker the intermolecular forces are, the higher the vapor pressure*:

Figure 12.15 The effect of temperature on the distribution of molecular speeds.

Figure 12.16 Vapor pressure as a function of temperature and intermolecular forces.

Figure 12.16 shows the vapor pressure of three liquids as a function of temperature:

- The effect of temperature is seen in the steeper rise as the temperature increases.
- The effect of intermolecular forces is seen in the values of the vapor pressure, the short, horizontal, dashed lines intersecting the vertical (pressure) axis at a given temperature (*vertical, dashed line at 20°C*). The dipole-dipole forces in polar diethyl ether, $\text{H}_3\text{CH}_2\text{COCH}_2\text{CH}_3$, are weaker than the H bonds in ethanol, $\text{CH}_3\text{CH}_2\text{OH}$, and the hydrogen bonding in ethanol is weaker than in water, H_2O , which can form four H bonds. Thus, diethyl ether has the highest vapor pressure and water has the lowest vapor pressure.

Quantifying the Effect of Temperature on Vapor Pressure The nonlinear relationship between vapor pressure and temperature is converted to a linear one with the **Clausius-Clapeyron equation**:

$$\ln P = \frac{-\Delta H_{\text{vap}}}{R} \left(\frac{1}{T} \right) + C$$

$y = m x + b$

where $\ln P$ is the natural logarithm of the vapor pressure, ΔH_{vap} is the heat of vaporization, R is the universal gas constant ($8.314 \text{ J/mol}\cdot\text{K}$), T is the absolute temperature, and C is a constant (not related to heat capacity). The equation is often used to find the heat of vaporization. The equation for a straight line is shown under it in blue, with $y = \ln P$, $x = 1/T$, m (the slope) $= -\Delta H_{\text{vap}}/R$, and b (the y-axis intercept) $= C$. A plot of $\ln P$ versus $1/T$ gives a straight line, as shown for diethyl ether and water in Figure 12.17.

A two-point version of the Clausius-Clapeyron equation allows us to calculate ΔH_{vap} if vapor pressures at two temperatures are known:

$$\ln \frac{P_2}{P_1} = \frac{\Delta H_{\text{vap}}}{R} \left(\frac{1}{T_1} - \frac{1}{T_2} \right) \quad (12.1)$$

If ΔH_{vap} and P_1 at T_1 are known, we can also calculate the vapor pressure (P_2) at any other temperature (T_2) or the temperature at any other pressure.

Figure 12.17 Linear plots of the relationship between vapor pressure and temperature. The slope is steeper for water because its ΔH_{vap} is greater.

SAMPLE PROBLEM 12.4 | Applying the Clausius-Clapeyron Equation

Problem The vapor pressure of ethanol is 119 torr at 34.9°C. If ΔH_{vap} of ethanol is 38.56 kJ/mol, calculate the temperature (in °C) when the vapor pressure is 760 torr.

Plan We are given ΔH_{vap} , P_1 , P_2 , and T_1 and substitute them into Equation 12.1 to solve for T_2 . The value of R here is 8.314 J/mol·K, so we must convert T_1 to K to obtain T_2 , and then convert T_2 back to °C.

Solution Convert the units of ΔH_{vap} to J/mol and the temperature to kelvins. Substituting the values into Equation 12.1 and solving for T_2 :

$$\ln \frac{P_2}{P_1} = \frac{\Delta H_{\text{vap}}}{R} \left(\frac{1}{T_1} - \frac{1}{T_2} \right)$$

$$T_1 = 34.9^\circ\text{C} + 273.15 = 308.0 \text{ K}$$

$$\ln \frac{760 \text{ torr}}{119 \text{ torr}} = \left(\frac{38.56 \times 10^3 \text{ J/mol}}{8.314 \text{ J/mol}\cdot\text{K}} \right) \left(\frac{1}{308.0 \text{ K}} - \frac{1}{T_2} \right)$$

$$1.854 = (4.64 \times 10^3 \text{ K}) \left[(3.247 \times 10^{-3} \text{ K}^{-1}) - \frac{1}{T_2} \right]$$

$$T_2 = 351 \text{ K}$$

Converting T_2 from K to °C:

$$T_2 = 351 \text{ K} - 273.15 = 78^\circ\text{C}$$

Check Round off to check the math. The change is in the right direction: higher P should occur at higher T .

FOLLOW-UP PROBLEMS

12.4A At 34.1°C, the vapor pressure of water is 40.1 torr. What is the vapor pressure at 85.5°C? The ΔH_{vap} of water is 40.65 kJ/mol.

12.4B Acetone is essential as an industrial solvent and a starting reactant in the manufacturing of countless products, from films to synthetic fibers. The vapor pressure of acetone is 24.50 kPa at 20.2°C and 10.00 kPa at 0.95°C. What is ΔH_{vap} of acetone?

SOME SIMILAR PROBLEMS 12.47–12.50

Vapor Pressure and Boiling Point Let's discuss what is happening when a liquid boils and then see the effect of pressure on boiling point.

1. *How a liquid boils.* In an *open* container, the weight of the atmosphere bears down on a liquid surface. As the temperature rises, molecules move more quickly throughout the liquid. At some temperature, the average E_k of the molecules in the liquid is great enough for them to form bubbles of vapor *in the interior*, and the liquid boils. At any lower temperature, the bubbles collapse as soon as they start to form because the external pressure is greater than the vapor pressure inside the bubbles. Thus, the **boiling point** is the temperature at which the vapor pressure inside bubbles in the liquid equals the external pressure, which is usually that of the atmosphere. As in condensation and freezing, once boiling begins, the temperature of the liquid remains constant until all of the liquid is gone.

2. *Effect of pressure on boiling point.* The boiling point of a liquid varies with elevation. At high elevations, a lower atmospheric pressure is exerted on the liquid surface, so molecules in the interior need less kinetic energy to form bubbles. Therefore, in mountainous regions, food takes *more* time to cook because the boiling point is lower and the boiling liquid is not as hot; for instance, in Boulder, Colorado (elevation 5430 ft, or 1655 m), water boils at 94°C. On the other hand, in a pressure cooker, food takes *less* time to cook because the boiling point is

higher at the higher pressure. Thus, *the boiling point is directly proportional to the applied pressure*:

higher P (applied) $\Rightarrow$ higher boiling point

The *normal boiling point* is observed at standard atmospheric pressure (760 torr, or 101.3 kPa; long, horizontal dashed line in Figure 12.16).

Boiling Point and Intermolecular Forces We have seen that a substance's vapor pressure is affected by the strength of its intermolecular forces (see Figure 12.16), with substances with weaker forces exhibiting greater vapor pressure at a particular temperature. We have also learned that a liquid boils when its vapor pressure equals the external pressure. Putting these two ideas together reveals that a liquid's boiling point is affected by the strength of the intermolecular forces (we used boiling points to compare the strength of intermolecular forces in Section 12.1). Although other factors affect boiling point, in general, *the weaker the intermolecular forces are, the lower the boiling point*:

weaker forces $\Rightarrow$ lower boiling point

Figure 12.16 shows that diethyl ether, with relatively weaker dipole-dipole forces, has a higher vapor pressure at a particular temperature than ethanol or water; therefore, the vapor pressure of diethyl ether equals an external pressure of 760 torr at a significantly lower temperature (34.4°C) than the other two liquids. Because water has relatively strong hydrogen bonds holding the water molecules tightly at the liquid surface, fewer water molecules enter the vapor phase at room temperature; a higher temperature is required to bring water's vapor pressure to 760 atm, so water has a higher boiling point.

Solid-Liquid Equilibria The particles in a crystal are continually jiggling about their fixed positions. As the temperature rises, the particles jiggle more rapidly, until some have enough kinetic energy to break free of their positions. At this point, melting begins. As more molecules enter the liquid (molten) phase, some collide with the solid and become fixed in position again. Because the phases remain in contact, a dynamic equilibrium is established when the melting rate equals the freezing rate. The temperature at which this occurs is called the **melting point**. The temperature remains fixed at the melting point until all the solid melts.

Because liquids and solids are nearly incompressible, pressure has little effect on the rates of melting and freezing: a plot of pressure versus temperature for a solid-liquid phase change is typically a *nearly* vertical straight line. In general, melting points do increase with increasing strength of intermolecular forces.

Solid-Gas Equilibria Sublimation is not very familiar because solids have *much* lower vapor pressures than liquids. A substance sublimates rather than melts because the intermolecular attractions are not great enough to keep the molecules near each other when they leave the solid state. Some solids *do* have high enough vapor pressures to sublime at ordinary conditions, including dry ice (carbon dioxide), iodine (Figure 12.18), and moth repellants, all of which consist of nonpolar molecules with weak dispersion forces.

The plot of pressure versus temperature for a solid-gas phase change reflects the large effect of temperature on vapor pressure; thus, it resembles the liquid-gas curve in rising steeply with higher temperatures.

Phase Diagrams: Effect of Pressure and Temperature on Physical State

The **phase diagram** of a substance combines the liquid-gas, solid-liquid, and solid-gas curves and gives the conditions of temperature and pressure at which each phase is stable and at which phase changes occur.

Figure 12.18 Iodine subliming. As the solid sublimates, I_2 vapor deposits on a cold surface (bottom of an ice-filled container). Source: Alexandre Dotta/Science Source

Figure 12.19 Phase diagram for CO_2 . (In both this figure and Figure 12.20, the slope of the solid-liquid line is exaggerated and the axes are not linear.)

The Phase Diagram for Carbon Dioxide and Most Substances The diagram for CO_2 , which is typical of most substances, has four general features (Figure 12.19):

1. *Regions of the diagram.* Each region presents the conditions of pressure and temperature at which the phase is stable. If another phase is placed under those conditions, it will change to the stable phase. In general, the solid is stable at low temperature and high pressure, the gas at high temperature and low pressure, and the liquid at intermediate conditions.

2. *Lines between regions.* The lines are the phase-transition curves discussed earlier. Any point along a line shows the pressure and temperature at which the phases are in equilibrium. The solid-liquid line has a slightly *positive* slope (slants to the *right* with increasing pressure) because, for most substances, the solid is more dense than the liquid: an increase in pressure converts the liquid to the solid. (Water is *the* major exception.)

3. *The triple point.* The three phase-transition curves meet at the **triple point**, at which all three phases are in equilibrium. As strange as it sounds, at the triple point in Figure 12.19, CO_2 is subliming and depositing, melting and freezing, and vaporizing and condensing simultaneously! Substances with several solid and/or liquid forms can have more than one triple point.

The CO_2 phase diagram shows why dry ice (solid CO_2) doesn't melt under ordinary conditions. The triple-point pressure is 5.1 atm, so liquid CO_2 doesn't occur at 1 atm because it is not stable. The horizontal dashed line at 1.0 atm crosses the solid-gas line, so when solid CO_2 is heated, it sublimates at -78°C rather than melts. If our normal atmospheric pressure were 5.2 atm, liquid CO_2 *would* occur; CO_2 does exist in the liquid phase in high-pressure fire extinguishers.

4. *The critical point.* Heat a liquid in a closed container and its density decreases. At the same time, more of the liquid vaporizes, so the density of the vapor increases. At the **critical point**, the two densities become equal and the phase boundary disappears. The temperature at the critical point is the *critical temperature* (T_c), and the pressure is the *critical pressure* (P_c). The average E_k is so high at this point that the vapor cannot be condensed at any pressure. The two most common gases in air have critical temperatures far below room temperature: O_2 cannot be condensed above -119°C , and N_2 cannot be condensed above -147°C .

Beyond the critical temperature, a *supercritical fluid* (SCF) exists rather than separate liquid and gaseous phases. An SCF expands and contracts like a gas and has unusual solvent properties. Supercritical CO_2 is used to extract caffeine from coffee beans, nicotine from tobacco, and fats from potato chips and acts as a dry cleaning agent. Lower the pressure, and the SCF disperses as a harmless gas. Supercritical H_2O dissolves nonpolar substances, even though liquid water cannot. Studies are under way to use supercritical H_2O for removing nonpolar organic toxins, such as PCBs, from industrial waste.

Figure 12.20 Phase diagram for H_2O .

The Solid-Liquid Line for Water The phase diagram for water differs from others in one major respect that reveals a key property. Unlike almost any other substance, the solid form is *less dense* than the liquid; that is, *water expands upon freezing*. Thus, the solid-liquid line has a *negative* slope (slants to the *left* with increasing pressure): an increase in pressure converts the solid to the liquid, and the higher the pressure, the lower the temperature at which water freezes (Figure 12.20). The vertical dashed line at -1°C crosses the solid-liquid line, which means that ice melts with only an increase in pressure.

The triple point of water occurs at low pressure (0.006 atm). Therefore, when solid water is heated at 1.0 atm (*horizontal dashed line*), the solid-liquid line is crossed at 0°C , the normal melting point. Thus, ice melts rather than sublimates. The horizontal dashed line crosses the liquid-gas curve at 100°C , the normal boiling point.

SAMPLE PROBLEM 12.5

Using a Phase Diagram to Predict Phase Changes

Problem Use the phase diagram for carbon (*see figure*) to describe the phase changes that a sample of carbon undergoes during the following:

- (a) The sample is heated at 10^2 bar (99 atm) from 1000 K to 5000 K.
 (b) The sample is then compressed at 5000 K to 10^6 bar (990,000 atm).

Plan We have to describe the phase changes due to heating at constant pressure (10^2 bar) and then compressing at constant temperature (5000 K).

(a) Using the phase diagram, we find the starting conditions (10^2 bar and 1000 K), the point labeled *a*, and draw a horizontal line from there to point *b*, at the ending conditions (10^2 bar and 5000 K). We note any phase-transition curves that the line crosses.

(b) Then, from the new starting conditions at point *b* (10^2 bar and 5000 K), we draw a vertical line to the ending pressure (10^6 bar) and note any phase-transition curves that this line crosses.

Solution (a) At 10^2 bar and 1000 K, the sample is in the form of solid graphite. As it is heated, the graphite sublimates and becomes carbon gas (at around 4400 K).

(b) As it is compressed at 5000 K, the gas first condenses to liquid carbon (at around 300 bar), which then solidifies to diamond (at around 3×10^5 bar).

Check (a) From the phase diagram, the first triple point occurs above 10^2 bar, so graphite will vaporize before it liquefies. (b) The liquid carbon will solidify to diamond because graphite does not exist at 5000 K under any pressure.

Comment Synthetic diamonds are made by compressing graphite at approximately 7×10^4 bar and 2300 K. The process occurs at a commercially useful rate when carried out in molten nickel. Traces of nickel remain in the diamonds, which are used for grinding tools and are not of gem quality.

FOLLOW-UP PROBLEMS

12.5A Describe the phase changes that a sample of carbon undergoes when it is heated at 3×10^2 bar from 2000 K (point *c* on the phase diagram in the sample problem) to 6000 K.

12.5B Describe the phase changes that a sample of carbon undergoes when it is compressed at 4600 K from 10^4 bar (point *d* on the phase diagram in the sample problem) to 10^6 bar.

SOME SIMILAR PROBLEMS 12.53 and 12.54

Summary of Section 12.3

- ▶ A heating-cooling curve depicts the change in temperature when a substance absorbs or releases heat at a constant rate. Within a phase, temperature (and average E_k) changes. During a phase change, temperature (and average E_k) is constant, but E_p changes. The total enthalpy change for the system is found using Hess's law.
- ▶ In a closed container, the liquid and gas phases of a substance reach equilibrium. The vapor pressure, the pressure of the gas at equilibrium, *increases* with temperature and *decreases* with the strength of the intermolecular forces.
- ▶ The Clausius-Clapeyron equation relates the vapor pressure to the temperature and is often used to find ΔH_{vap} .
- ▶ A liquid in an open container boils when the vapor pressure inside bubbles forming in the liquid equals the external pressure.
- ▶ Solid-liquid equilibrium occurs at the melting point. Some solids sublime because they have very weak intermolecular forces.
- ▶ The phase diagram of a substance shows the phase that is stable at any P and T , the conditions at which phase changes occur, and the conditions at the critical point and the triple point. Water differs from most substances in that its solid phase is less dense than its liquid phase, so its solid-liquid line has a negative slope.

Figure 12.21 The molecular basis of surface tension.

12.4 PROPERTIES OF THE LIQUID STATE

Of the three states, only liquids combine the ability to flow with the effects of strong intermolecular forces. We understand this state least at the molecular level. Because of the *random* arrangement of the particles in a gas, any region of the sample is virtually identical to any other. And different regions of a crystalline solid are identical because of the *orderly* arrangement of the particles (see Section 12.6). Liquids, however, have regions that are orderly one moment and random the next. Nevertheless, many macroscopic properties, such as surface tension, capillarity, and viscosity, are well understood.

Surface Tension

Intermolecular forces have different effects on a molecule at the surface than on one in the interior (Figure 12.21):

- An interior molecule is attracted by others on all sides.
- A surface molecule is only attracted by others below and to the sides, so it experiences a *net attraction downward*.

Therefore, to increase attractions and become more stable, a surface molecule tends to move into the interior. For this reason, *a liquid surface has the fewest molecules and, thus, the smallest area possible*. In effect, the surface behaves like a “taut skin” covering the interior.

The only way to increase the surface area is for molecules to move up by breaking attractions in the interior, which requires energy. The **surface tension** is the energy required to increase the surface area by a given amount and has units of J/m^2 . This property is dependent on the intermolecular forces present and the temperature:

- In general, *the stronger the intermolecular forces between particles, the more energy it takes to increase the surface area, so the greater the surface tension* (Table 12.3). Water has a high surface tension because its molecules form multiple H bonds. *Surfactants* (surface-active agents), such as soaps, petroleum recovery agents, and fat emulsifiers, decrease the surface tension of water by congregating at the surface and disrupting the H bonds.
- Surface tension *decreases with increasing temperature*. For example, the surface tension of water is $7.3 \times 10^{-2} \text{ J/m}^2$ at 20°C , $6.8 \times 10^{-2} \text{ J/m}^2$ at 50°C , and $6.1 \times 10^{-2} \text{ J/m}^2$ at 90°C . At higher temperatures, the liquid molecules have increased kinetic energy with which to break attractions to molecules in the interior. Hot water is more effective than cold water at cleaning greasy dishes, as the lower surface tension of hot water allows it to “wet” the surface of the dish to a greater extent. The surfactants in the soap further decrease water’s surface tension.

Table 12.3 | Surface Tension, Viscosity, and Forces Between Particles

Substance	Formula	Surface Tension (J/m^2) at 20°C	Viscosity ($\text{N}\cdot\text{s/m}^2$) at 20°C	Major Force(s)
Diethyl ether	$\text{CH}_3\text{CH}_2\text{OCH}_2\text{CH}_3$	1.7×10^{-2}	0.240×10^{-3}	Dipole-dipole; dispersion
Ethanol	$\text{CH}_3\text{CH}_2\text{OH}$	2.3×10^{-2}	1.20×10^{-3}	H bonding
Butanol	$\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{OH}$	2.5×10^{-2}	2.95×10^{-3}	H bonding; dispersion
Water	H_2O	7.3×10^{-2}	1.00×10^{-3}	H bonding
Mercury	Hg	48×10^{-2}	1.55×10^{-3}	Metallic bonding

Surface tension is the cause of many familiar phenomena. Bubbles are round because this shape minimizes the surface area around the gas, and surface tension is the reason some insects can walk on water (*see photo*).

Capillarity

The rising of a liquid against the pull of gravity through a narrow space, such as a thin tube, is called *capillary action*, or **capillarity**. Capillarity results from a competition between the intermolecular forces within the liquid (cohesive forces) and those between the liquid and the tube walls (adhesive forces). Let's look at the difference between the capillarities of water and mercury in glass:

1. *Water in glass.* When you place a narrow glass tube in water, why does the liquid rise up the tube and form a concave meniscus? Glass is mostly silicon dioxide (SiO_2), so water molecules form adhesive H-bonding forces with the O atoms of the glass. As a result, a thin film of water creeps up the wall. At the same time, cohesive H-bonding forces between water molecules, which give rise to surface tension, make the surface taut. These adhesive and cohesive forces combine to raise the water level and produce the concave meniscus (Figure 12.22A). The liquid rises until gravity pulling down is balanced by adhesive forces pulling up.

2. *Mercury in glass.* When you place a glass tube in a dish of mercury, why does the liquid drop below the level in the dish and form a convex meniscus? The cohesive forces among the mercury atoms are metallic bonds, so they are *much* stronger than the mostly dispersion adhesive forces between mercury and glass. As a result, the liquid pulls away from the walls. At the same time, the surface atoms are being pulled toward the interior by mercury's high surface tension, so the level drops. These combined forces produce the convex meniscus seen in a laboratory barometer (Figure 12.22B).

Capillarity plays a key role in many everyday events. The adhesive forces between water and a nonpolar surface are much weaker than the cohesive (H-bond) forces within water. As a result, water pulls away from a nonpolar surface and forms beaded droplets, as on a freshly waxed car or on the waxy coating of a leaf after a rainfall. Even more familiar, after a shower, capillary action draws water away from your body through the closely spaced fibers in the cotton towel, which is made of cellulose molecules, so the water molecules also form H bonds with the —OH groups of cellulose.

Viscosity

Viscosity is the resistance of a fluid to flow, and it results from intermolecular attractions that impede the movement of molecules around and past each other. Both gases and liquids flow, but liquid viscosities are *much* higher because the much shorter distances

Because of its widespread legs, a water strider doesn't exert enough pressure to exceed the surface tension.

Table 12.4 Viscosity of Water at Several Temperatures

Temperature (°C)	Viscosity (N·s/m ²)*
20	1.00×10^{-3}
40	0.65×10^{-3}
60	0.47×10^{-3}
80	0.35×10^{-3}

*The units of viscosity are newton-seconds per square meter.

between the particles of a liquid result in many more points for intermolecular forces to act. Intermolecular forces, temperature, and molecular shape influence viscosity:

- In general, *the stronger the intermolecular forces between particles, the higher the viscosity* (see Table 12.3), since stronger attractions prevent molecules from moving past each other freely.
- *Viscosity decreases with increasing temperature* (Table 12.4). Faster moving molecules overcome intermolecular forces more easily, so the resistance to flow decreases with increasing temperature. Next time you heat cooking oil, watch the oil flow more easily and spread out in the pan as it warms.
- *Viscosity is affected by molecular shape*. Small, spherical molecules make little contact and pour easily, like buckshot from a bowl. Long molecules make more contact and become entangled and pour slowly, like cooked spaghetti from a bowl. Thus, given the same types of intermolecular forces, liquids consisting of longer molecules have higher viscosities. As shown in Table 12.3, the viscosity of the longer butanol molecule is greater than that of the shorter ethanol molecule.

To protect engine parts during long drives, motor oils contain *polymeric viscosity improvers*. As the oil warms, these additive molecules change from compact spheres to long strands that become tangled with the long hydrocarbon molecules of the oil. Greater dispersion forces increase the viscosity to compensate for the thinning of the oil due to heating.

Summary of Section 12.4

- › Surface tension is a measure of the energy required to increase a liquid's surface area. Greater intermolecular forces within a liquid create higher surface tension.
- › Capillarity, the rising of a liquid through a narrow space, occurs when the forces between a liquid and a surface (adhesive) are greater than those in the liquid (cohesive).
- › Viscosity, the resistance to flow, depends on molecular shape and decreases with temperature. Stronger intermolecular forces create higher viscosity.

12.5 THE UNIQUENESS OF WATER

Water is absolutely amazing stuff, with some of the most unusual properties of any substance, but it is so familiar we take it for granted. Like any substance, its properties arise inevitably from those of its atoms. Each O and H atom attains a filled outer level by sharing electrons in single bonds. With two bonding pairs and two lone pairs around O and a large electronegativity difference in each O—H bond, the H₂O molecule is bent and highly polar. This arrangement is crucial because it allows each molecule to engage in four H bonds with its neighbors (Figure 12.23). From these basic atomic and molecular facts emerges some unique and remarkable macroscopic behavior.

Figure 12.23 H-bonding ability of water. One H₂O molecule can form four H bonds to other molecules, resulting in a tetrahedral arrangement.

Solvent Properties of Water

The *great solvent power* of water results from its polarity and H-bonding ability:

- It dissolves ionic compounds through ion-dipole forces that separate the ions from the solid and keep them in solution (see Figure 4.5).
- It dissolves polar nonionic substances, such as ethanol (CH₃CH₂OH) and glucose (C₆H₁₂O₆), by H bonding.
- It dissolves nonpolar atmospheric gases to a limited extent through a type of force we will discuss in Chapter 13.

Water is the environmental and biological solvent, forming the complex solutions we know as oceans, lakes, and cellular fluid. Aquatic animals could not survive without dissolved O₂, nor could aquatic plants without dissolved CO₂. Tiny marine animals

form coral reefs made of carbonates from dissolved CO_2 and HCO_3^- . From a chemical point of view, all organisms, from bacteria to humans, are highly organized systems of membranes enclosing and compartmentalizing complex aqueous solutions.

Thermal Properties of Water

When a substance is heated, some of the added energy increases average molecular speed, some increases molecular vibration and rotation, and some is used to overcome intermolecular forces.

1. *Specific heat capacity.* Because water has so many strong H bonds, its *specific heat capacity* is higher than that of any common liquid. With oceans covering 70% of Earth's surface, daytime energy from the Sun causes relatively small changes in temperature, allowing life to survive. On the waterless, airless Moon, temperatures range from 100°C to -150°C during a complete lunar day. Even in Earth's deserts, day-night temperature differences of 40°C are common.

2. *Heat of vaporization.* Numerous strong H bonds give water a very *high heat of vaporization*. Two examples show why this is crucial. The average adult has 40 kg of body water and generates about 10,000 kJ of heat a day from metabolism. If this heat were used to increase the average E_k of water molecules in the body, the rise in body temperature of tens of degrees would mean immediate death. Instead, the heat is converted to E_p as it breaks H bonds and evaporates sweat, resulting in a stable body temperature and minimal loss of body fluid. On a planetary scale, the Sun's energy vaporizes ocean water in warm latitudes, and the potential energy is released as heat to warm cooler regions when the vapor condenses to rain. This global-scale cycling of water powers many weather patterns.

Surface Properties of Water

Hydrogen bonding is also responsible for water's *high surface tension* and *high capillarity*. Except for some molten metals and salts, water has the highest surface tension of any liquid. It keeps plant debris resting on a pond surface, providing shelter and nutrients for fish and insects. High capillarity means water rises through the tiny spaces between soil particles, so plant roots can absorb deep groundwater during dry periods.

The Unusual Density of Solid Water

In the solid state, the tetrahedral arrangement of H-bonded water molecules (see Figure 12.23) leads to the hexagonal, *open structure* of ice (Figure 12.24A), and the symmetrical beauty of snowflakes (Figure 12.24B) reflects this hexagonal organization. The large spaces within ice make *the solid less dense than the liquid* and explain the negative slope of the solid-liquid line in the phase diagram for water (see Figure 12.20). As pressure is applied, some H bonds break, so the crystal structure is disrupted, and the ice liquefies. When ice melts at 0°C , the loosened molecules pack much more closely, filling spaces in the collapsing solid structure. As a result, liquid water is most dense (1.000 g/mL) at around 4°C (3.98°C). With more heating, the density decreases through normal thermal expansion. This behavior has major effects in nature:

- *Surface ice of lakes.* When the surface of a lake freezes in winter, the ice floats. If the solid were denser than the liquid, as is true for nearly every other substance, the surface water would freeze and sink until the entire lake was solid. Aquatic life would not survive from year to year.
- *Nutrient turnover.* As lake water becomes colder in early winter, it becomes more dense *before* it freezes. Similarly, in spring, less dense ice thaws to form more dense water *before* the water expands. During both of these seasonal

Figure 12.25 The unique macroscopic behavior of water that emerges from its atomic and molecular properties.

density changes, the top layer of water reaches maximum density first and sinks. The next layer of water rises because it is slightly less dense, reaches 4°C, and likewise sinks. This alternation of sinking and rising distributes nutrients and dissolved oxygen.

- *Soil formation.* When rain fills crevices in rocks and freezes, an outward force is applied that is relieved when the ice melts. In time, this repeated freeze-thaw stress cracks the rock. Over eons, this effect helps produce sand and soil.

The far-reaching consequences of the properties of water illustrate chemistry's central theme: the macroscopic world we know is the cumulative outcome of the atomic world we seek to know (Figure 12.25).

› Summary of Section 12.5

- › The atomic properties of H and O result in water's bent molecular shape, polarity, and H-bonding ability.
- › These properties give water the ability to dissolve many ionic and polar compounds.
- › Water's high specific heat capacity and heat of vaporization give Earth and its organisms a narrow temperature range.
- › Water's high surface tension and capillarity are essential to plants and animals.
- › Because water expands on freezing, lake life survives in winter, nutrients mix from seasonal density changes, and soil forms through freeze-thaw stress on rocks.

12.6 THE SOLID STATE: STRUCTURE, PROPERTIES, AND BONDING

Stroll through a museum's mineral collection, and you'll be struck by the variety and beauty of crystalline solids. In this section, we discuss the structural features of these and other solids and the intermolecular forces that create them. We also consider the main bonding model that explains many properties of solids.

Figure 12.26 The beauty of crystalline solids. **A**, Wulfenite. **B**, Barite. **C**, Beryl (emerald). **D**, Quartz (amethyst).

Source: (A) Matteo Chinellato/Shutterstock (B) Albert Russ/Shutterstock (C) dipressionist/123RF (D) Doug Sherman/Geofile

Structural Features of Solids

We can divide solids into two broad categories:

- **Crystalline solids** have well-defined shapes because their particles—atoms, molecules, or ions—occur in an orderly arrangement (Figure 12.26).
- **Amorphous solids** have poorly defined shapes because their particles do not have an orderly arrangement throughout a sample.

The Crystal Lattice and the Unit Cell The particles in a crystal are packed tightly in an orderly, three-dimensional array. As the simplest case, consider the particles as *identical* spherical atoms, and imagine a point at the center of each. The collection of points forms a regular pattern called the crystal **lattice**. The lattice consists of *all points with identical surroundings*; that is, there would be no way to tell if you moved from one lattice point to another.

Figure 12.27A shows a portion of a lattice and the **unit cell**, the *smallest* portion that yields the crystal if it is repeated in all directions. A two-dimensional analogy for a unit cell and the resulting crystal lattice is a checkerboard (Figure 12.27B), a section of tiled floor, or any pattern that is constructed from a repeating unit.

Figure 12.27 The crystal lattice and the unit cell. **A**, A small portion of a lattice is shown as points connected by lines, with a unit cell (colored). **B**, A checkerboard as a two-dimensional analogy for a lattice.

There are 7 crystal systems and 14 types of unit cells that occur in nature, but we will be concerned primarily with the *cubic system*. The solid states of a majority of metallic elements, some covalent compounds, and many ionic compounds occur as cubic lattices. A key parameter of any lattice is the **coordination number**, the number of *nearest* neighbors of a particle in a crystal. There are three types of cubic unit cells:

1. In the **simple cubic unit cell** (Figure 12.28A), the centers of eight identical particles define the corners of a cube (shown in the expanded view, *top row*). The particles touch along the cube edges (see the space-filling view, *second row*), but they do not touch diagonally along the cube faces or through its center. An

Figure 12.28 The three cubic unit cells. **A**, Simple cubic unit cell. **B**, Body-centered cubic unit cell. **C**, Face-centered cubic unit cell. *Top row:* Cubic arrangements of atoms in expanded view. *Second row:* Space-filling view of these cubic arrangements. All atoms are identical but, for clarity, corner atoms are blue, body-centered atoms pink, and face-centered atoms yellow. *Third row:* A unit cell (shaded blue) in an expanded portion of the crystal. The number of nearest neighbors around one particle (dark blue in center) is the coordination number. *Bottom row:* The total numbers of atoms in the actual unit cells. The simple cubic has one atom, the body-centered has two, and the face-centered has four.

expanded portion of the crystal (*third row*) shows that the coordination number of each particle is 6: a particle has four neighboring particles in its own layer, one in the layer above, and one in the layer below.

2. In the **body-centered cubic unit cell** (Figure 12.28B), identical particles lie at each corner *and* in the center of the cube. Those at the corners do not touch each other, but they all touch the one in the center. Each particle is surrounded

by eight nearest neighbors, four above and four below, so the coordination number is 8.

3. In the **face-centered cubic unit cell** (Figure 12.28C), identical particles lie at each corner *and* in the center of each face but not in the center of the cube. Particles at the corners touch those in the faces but not each other. The coordination number is 12.

How many particles make up a unit cell? For particles of the same size, *the higher the coordination number, the greater the number of particles in a given volume*. Since one unit cell touches another, with no gaps, a particle at a corner or face is *shared* by adjacent cells. In the cubic unit cells, the particle at each corner is part of eight adjacent cells (see Figure 12.28, *third row*), so one-eighth of each particle belongs to each cell (*bottom row*). There are eight corners in a cube, so

- A simple cubic unit cell contains $8 \times \frac{1}{8}$ particle = 1 particle.
- A body-centered cubic unit cell contains $8 \times \frac{1}{8}$ particle = 1 particle plus 1 particle in the center, for a total of 2 particles.
- A face-centered cubic unit cell contains $8 \times \frac{1}{8}$ particle = 1 particle plus one-half particle in each of the six faces $6 \times \frac{1}{2}$ particle = 3 particles, for a total of 4 particles.

SAMPLE PROBLEM 12.6

Determining the Number of Particles per Unit Cell and the Coordination Number

Problem For each of the crystalline solids shown, determine the number of atoms (or ions) per unit cell and the coordination number.

Plan To determine the number of particles (atoms or ions) in a unit cell, we count the number of particles at the corners, in the faces, and within the body of the cell. The eight corners are shared by eight other cells for a total of $8 \text{ corners} \times \frac{1}{8}$ particle per corner, or 1 particle; particles in the body of a cell are in that cell only; particles in the faces are shared by two cells, $6 \text{ faces} \times \frac{1}{2}$ particle per face, or 3 particles. We count the number of nearest neighboring particles to obtain the coordination number.

Solution (a) Palladium metal adopts a face-centered cubic unit cell:

$$\text{Atoms/unit cell} = (8 \times \frac{1}{8}) + (6 \times \frac{1}{2}) = 4 \text{ atoms}$$

The coordination number is 12.

(b) Copper(I) iodide has a unit cell that can be viewed as a face-centered cubic array of Cu^+ ions interpenetrating a face-centered cubic array of I^- ions:

$$\text{Cu}^+ \text{ ions within the body of the unit cell} = 4 \text{ Cu}^+ \text{ ions}$$

$$\text{I}^- \text{ ions/unit cell} = (8 \times \frac{1}{8}) + (6 \times \frac{1}{2}) = 4 \text{ I}^- \text{ ions}$$

Each ion is surrounded by four of the oppositely charged ions: coordination number is 4.

(c) Molybdenum metal adopts a body-centered cubic unit cell:

$$\text{Atoms/unit cell} = (8 \times \frac{1}{8}) + (1 \times 1) = 2 \text{ atoms}$$

The coordination number is 8.

Check Using Figure 12.28, we see that the values are correct.

FOLLOW-UP PROBLEMS

12.6A For each of the following crystalline solids, determine the number of atoms (or ions) per unit cell and the coordination number:

(a) PbS

(b) W

(c) Al

(a) Pd

(b) CuI

(c) Mo

12.6B For each of the following crystalline solids, determine the number of atoms (or ions) per unit cell and the coordination number:

(a) K

(b) Pt

(c) CsCl

SOME SIMILAR PROBLEMS 12.87, 12.96, 12.97, 12.98(a), and 12.99(a)

The efficient packing of fruit.

Source: Bryan Busovicki/Shutterstock

Packing Efficiency and the Creation of Unit Cells Unit cells result from the ways atoms pack together, which are similar to the ways that macroscopic spheres—marbles, golf balls, fruit—are packed (*see photo*). Let's pack *identical* spheres to create the three cubic unit cells we just discussed and the hexagonal unit cell and determine the **packing efficiency**, the percentage of the total volume of the unit cell occupied by the spheres themselves:

1. *The simple cubic unit cell.* When we arrange the first layer of spheres in vertical and horizontal rows, large, diamond-shaped spaces are formed (Figure 12.29A, *cutaway portion*). If we place the next layer of spheres *directly above* the first, we obtain an arrangement based on the *simple cubic unit cell* (Figure 12.29B). The spheres occupy only 52% of the unit-cell volume, so 48% is empty space between them. This is a very inefficient way to pack spheres, so neither fruit nor atoms are typically packed this way.

2. *The body-centered cubic unit cell.* Rather than placing the second layer (colored *green* for clarity) directly above the first, we use space more efficiently by placing its spheres over the diamond-shaped spaces in the first layer (Figure 12.29C). Then we pack the third layer onto the diamond-shaped spaces in the second, which makes the first and third layers line up vertically. This arrangement is based on the *body-centered cubic unit cell*, and its packing efficiency, at 68%, is much higher than that of the simple cubic unit cell. Several metallic elements, including chromium, iron, and all the Group 1 elements, have a crystal structure based on this unit cell.

3. *The hexagonal and face-centered cubic unit cells.* Spheres are packed most efficiently in these cells. First, in the bottom layer (labeled *a*, *orange*), we shift every other row laterally so that the large, diamond-shaped spaces become smaller, triangular spaces. Then we place the second layer (*b*, *green*) over these spaces (Figure 12.29D).

In layer *b*, notice that some spaces are orange because they lie above *spheres* in layer *a*, whereas other spaces are white because they lie above *spaces* in layer *a*. We can place the third layer in either of two ways, giving rise to two different unit cells:

- *Hexagonal unit cell.* If we place the third layer of spheres (*orange*) over the orange spaces (look down and left to Figure 12.29E), they lie directly over the spheres in layer *a*. Every other layer is placed identically (an *abab . . .* layering pattern), and we obtain **hexagonal closest packing**, which is based on the *hexagonal unit cell*.
- *Face-centered unit cell.* If we place the third layer of spheres (*blue*) over the white spaces in layer *b* (look down and right to Figure 12.29F), the placement is different from layers *a* and *b* (an *abcabc . . .* pattern), and we obtain **cubic closest packing**, which is based on the *face-centered cubic unit cell*.

Figure 12.29 Packing spheres to obtain three cubic and hexagonal unit cells. **A**, In the first layer, each sphere lies next to another horizontally and vertically; note the large, diamond-shaped spaces (see cutaway). **B**, If the spheres in the next layer lie directly over those in the first, the packing is based on the simple cubic unit cell (pale orange cube, lower right corner). **C**, If the spheres in the next layer lie in the diamond-shaped spaces of the first layer, the packing is based on the body-centered cubic unit cell (lower right corner). **D**, The closest possible packing of the first layer (layer *a*, orange) is obtained by shifting every other row in part A to obtain smaller, triangular spaces. The spheres of the second layer (layer *b*, green) are placed above these spaces; note the orange and white spaces that result. **E**, When the third layer (next layer *a*, orange) is placed over the orange spaces, we obtain an *abab...* pattern and the hexagonal unit cell. **F**, When the third layer (layer *c*, blue) covers the white spaces, we get an *abcabc...* pattern and the face-centered cubic unit cell.

The packing efficiency with both hexagonal and cubic closest packing is 74%, and the coordination number of both types of unit cells is 12. Most metallic elements crystallize in one or the other of these arrangements. Magnesium, titanium, and zinc are some that adopt the hexagonal structure; nickel, copper, and lead adopt the cubic closest packing structure, as do many ionic compounds and other substances, such as CO_2 , CH_4 , and most noble gases.

In Sample Problem 12.7, we use the density of a metal and our knowledge of unit cells to find an atomic radius.

SAMPLE PROBLEM 12.7 | Determining Atomic Radius

Problem Barium is the largest nonradioactive alkaline earth metal. It has a body-centered cubic unit cell and a density of 3.62 g/cm^3 . What is the atomic radius of barium? (Volume of a sphere: $V = \frac{4}{3}\pi r^3$.)

Plan An atom is spherical, so we can find its radius from its volume. Use the density to find the volume of 1 mol (137.3 g) of Ba. The metal crystallizes in the body-centered cubic structure, so only 68% of this volume is occupied by 1 mol of the Ba atoms themselves (see Figure 12.29C). Dividing by Avogadro's number gives the volume of one Ba atom, from which we find the radius. (See the road map.)

Solution Combining steps to find the volume of 1 mol of Ba metal:

$$\text{Volume/mol of Ba metal} = \frac{137.33 \text{ g Ba}}{1 \text{ mol Ba}} \times \frac{1 \text{ cm}^3}{3.62 \text{ g Ba}} = 37.9 \text{ cm}^3/\text{mol Ba}$$

Finding the volume (cm^3) of 1 mol of Ba atoms:

$$\begin{aligned} \text{Volume/mole of Ba atoms} &= \text{cm}^3/\text{mol Ba} \times \text{packing efficiency} \\ &= 37.9 \text{ cm}^3/\text{mol Ba} \times 0.68 \\ &= 26 \text{ cm}^3/\text{mol Ba atoms} \end{aligned}$$

Finding the volume of one Ba atom:

$$\begin{aligned} \text{Volume of Ba atom} &= \frac{26 \text{ cm}^3}{1 \text{ mol Ba atoms}} \times \frac{1 \text{ mol Ba atoms}}{6.022 \times 10^{23} \text{ Ba atoms}} \\ &= 4.3 \times 10^{-23} \text{ cm}^3/\text{Ba atom} \end{aligned}$$

Finding the atomic radius of Ba from the volume of a sphere:

$$V \text{ of Ba atom} = \frac{4}{3}\pi r^3 \quad \text{so} \quad r^3 = \frac{3V}{4\pi}$$

Thus,

$$r = \sqrt[3]{\frac{3V}{4\pi}} = \sqrt[3]{\frac{3(4.3 \times 10^{-23} \text{ cm}^3)}{4 \times 3.14}} = 2.2 \times 10^{-8} \text{ cm}$$

Check The order of magnitude is correct for an atom ($\sim 10^{-8} \text{ cm} \approx 10^{-10} \text{ m}$). The actual value for barium is, in fact, $2.22 \times 10^{-8} \text{ cm}$ (see Figure 8.12).

FOLLOW-UP PROBLEMS

12.7A Cobalt has a face-centered cubic unit cell and an atomic radius of 125 pm. Calculate the density of cobalt metal.

12.7B Iron crystallizes in a body-centered cubic structure. The volume of one Fe atom is $8.38 \times 10^{-24} \text{ cm}^3$, and the density of Fe is 7.874 g/cm^3 . Calculate an approximate value for Avogadro's number.

SOME SIMILAR PROBLEMS 12.88 and 12.89

Our understanding of crystal structures comes from our ability to “see” them. Two techniques for visualizing crystal structures are described in the upcoming Tools of the Laboratory.

Road Map

Figure 12.30 Edge length and atomic (ionic) radius in the three cubic unit cells.

The edge length of the unit cell is obtained from x-ray crystallography. We can then apply the Pythagorean theorem and some arithmetic to find atomic (or ionic) radii in the three cubic unit cells (Figure 12.30). Sample Problem 12.8 applies this approach.

SAMPLE PROBLEM 12.8 | Determining Atomic Radius from the Unit Cell

Problem Copper adopts cubic closest packing, and the edge length of the unit cell is 361.5 pm. What is the atomic radius of copper?

Plan Cubic closest packing gives a face-centered cubic unit cell, and we know the edge length. From Figure 12.30, with $A = 361.5$ pm, we solve for r .

Solution Using the Pythagorean theorem to find C , the diagonal of the cell's face:

$$C = \sqrt{A^2 + B^2}$$

The unit cell is a cube, so $A = B$. Therefore,

$$C = \sqrt{2A^2} = \sqrt{2(361.5 \text{ pm})^2} = 511.2 \text{ pm}$$

Finding r : $C = 4r$. Therefore,

$$r = 511.2 \text{ pm}/4 = 127.8 \text{ pm}$$

We can combine these steps by using the equation presented in Figure 12.30:

$$A = \sqrt{8}r$$

$$r = 361.5 \text{ pm}/\sqrt{8} = 127.8 \text{ pm}$$

Check Rounding and quickly checking the math give

$$C = \sqrt{2(4 \times 10^2 \text{ pm})^2} = \sqrt{2(16 \times 10^4 \text{ pm}^2)}$$

or $\sim 500\text{--}600$ pm; thus, $r \approx 125\text{--}150$ pm. The actual value for copper is 128 pm (see Figure 8.12).

FOLLOW-UP PROBLEMS

12.8A Iron crystallizes in a body-centered cubic structure. If the atomic radius of Fe is 126 pm, find the edge length (in nm) of the unit cell.

12.8B Aluminum crystallizes in a cubic closest packed structure. If the edge length of the unit cell is 0.405 nm, find the atomic radius (in pm).

SOME SIMILAR PROBLEMS 12.92 and 12.93

Various tools exist for measuring atomic-scale dimensions, and two of the most powerful are **x-ray diffraction analysis** and **scanning tunneling microscopy**.

X-Ray Diffraction Analysis

In Chapter 7, we saw how diffraction patterns of bright and dark regions appear when light passes through slits spaced as far apart as the wavelength (see Figure 7.5). X-ray wavelengths are about the same size as the spaces between layers of spheres in a crystal, so we use the spaces as “slits” to diffract x-rays.

As one example, let’s use this approach to measure the distance (d) between two adjacent layers of atoms in a simplified lattice (Figure B12.1). Two waves impinge on the crystal at an angle θ and are diffracted at that angle by the layers. When the

Figure B12.1 Diffraction of x-rays by crystal planes.

first wave strikes the top layer and the second strikes the next layer, they are *in phase* (peaks aligned with peaks and troughs with troughs). If they are still in phase after being diffracted, they form a spot on a photographic plate. This will occur only if the additional distance traveled by the second wave ($DE + EF$ in the figure) is a whole number of wavelengths, $n\lambda$, where n is a positive integer referred to as the *order* of the diffraction. From trigonometry, we find that

$$n\lambda = 2d \sin \theta$$

where θ is the angle of incoming light and d , the unknown, is the distance between layers. This is the *Bragg equation*, named for W. H. Bragg and his son W. L. Bragg, who shared the Nobel Prize in physics in 1915 for their work on crystal structure analysis.

Rotating the crystal changes θ and produces different sets of spots. Eventually, the complete diffraction pattern reveals distances and angles in the lattice (Figure B12.2). X-ray diffraction analysis is used in many studies, but its greatest recent impact is uncovering the structures of DNA and proteins.

Scanning Tunneling Microscopy

This technique, invented by Gerd Binnig and Heinrich Rohrer, who won the Nobel Prize in physics in 1986, is used to observe surfaces. It is based on the idea that an electron has a small, but finite, probability of being so far from its nucleus that it can move (“tunnel”) closer to another atom.

In practice, an extremely sharp tungsten-tipped probe, the source of the tunneling electrons, is placed very close to (about 0.5 nm from) the surface under study. A small applied electric

Figure B12.2 Formation of an x-ray diffraction pattern of the protein hemoglobin. **A**, A sample of crystalline protein is rotated to obtain different angles of incoming and diffracted x-rays. **B**, The diffraction pattern is a complex series of spots. **C**, Computerized analysis provides a picture of the molecule.

potential increases the probability that the electrons will tunnel across this minute gap. The probe moves tiny distances up and down to maintain the constant current across the gap, thus following the surface at the atomic scale. This movement is monitored electronically, and, after many scans, a three-dimensional map of the surface is obtained. The method has revealed images of atoms and molecules coated on surfaces and is being used to study the nature of defects and many other surface features (Figure B12.3).

Problems

B12.1 X-rays of wavelength $\lambda = 0.709 \times 10^{-10}$ m undergo a first-order ($n = 1$) diffraction of 11.6° when aimed at crystalline nickel. What is the spacing between layers of Ni atoms?

B12.2 A first-order ($n = 1$) diffraction of x-rays aimed at a crystal of NaCl occurs at 15.9° .

- What is the wavelength (in pm) of the x-rays?
- At what angle would a second-order ($n = 2$) diffraction appear?

Types and Properties of Crystalline Solids

The five most important types of solids are defined by the type(s) of particle(s) in the crystal (Table 12.5). We'll highlight interparticle forces and physical properties.

Table 12.5 | Characteristics of the Major Types of Crystalline Solids

Type	Particle(s)	Interparticle Forces	Physical Properties	Examples [mp, °C]
Atomic	Atoms	Dispersion	Soft, very low mp, poor thermal and electrical conductors	Elements in Group 18 (Ne [−249] to Rn [−71])
Molecular	Molecules	Dispersion, dipole-dipole, H bonds	Fairly soft, low to moderate mp, poor thermal and electrical conductors	<i>Nonpolar*</i> O ₂ [−219], C ₄ H ₁₀ [−138] Cl ₂ [−101], C ₆ H ₁₄ [−95], P ₄ [44.1] <i>Polar</i> SO ₂ [−73], CHCl ₃ [−64], HNO ₃ [−42], H ₂ O [0.0], CH ₃ COOH [17]
Ionic	Positive and negative ions	Ion-ion attraction	Hard and brittle, high mp, good thermal and electrical conductors when molten	NaCl [801] CaF ₂ [1423] MgO [2852]
Metallic	Atoms	Metallic bond	Soft to hard, low to very high mp, excellent thermal and electrical conductors, malleable and ductile	Na [97.8] Zn [420] Fe [1535]
Network covalent	Atoms	Covalent bond	Very hard, very high mp, usually poor thermal and electrical conductors	SiO ₂ (quartz) [1610] C (diamond) [~4000]

*Nonpolar molecular solids are arranged in order of increasing molar mass. Note the correlation with increasing melting point (mp).

Figure 12.31 Cubic closest packing of argon (face-centered cubic unit cell).

Figure 12.32 Cubic closest packing (face-centered unit cell) of CH₄.

Atomic Solids Individual atoms held together only by *dispersion forces* occupy the lattice points in an **atomic solid**:

- The noble gases (Group 18) are the only substances that form atomic solids.
- The very weak dispersion forces among the atoms mean melting and boiling points and heats of vaporization and fusion are all very low, rising smoothly with increasing molar mass.

Argon crystallizes in a cubic closest packed structure (Figure 12.31), as do the other noble gases.

Molecular Solids In the many thousands of **molecular solids**, individual molecules occupy the lattice points. Various combinations of dipole-dipole, dispersion, and H-bonding forces account for a wide range of physical properties:

- Dispersion forces in nonpolar substances lead to melting points that generally increase with molar mass (see Table 12.5).
- Among polar molecules, dipole-dipole forces and, where possible, H bonding occur.
- Most molecular solids have much higher melting points than atomic solids (noble gases) but much lower melting points than other types of solids.

Methane crystallizes in a face-centered cubic structure with the center of each carbon as the lattice point (Figure 12.32).

Ionic Solids Ionic compounds arrange their ions in **ionic solids**; cations are surrounded by as many anions as possible, and vice versa, to maximize attractions, with the smaller of the ions (usually the cation) lying in the spaces (holes) formed by the packing of the larger (usually the anion). The unit cell is the smallest portion that maintains the composition; that is, *the unit cell has the same cation/anion ratio as the empirical formula*. As a result of cation-anion contact, the interparticle forces (ionic bonds) are *much* stronger than the van der Waals forces in atomic or molecular solids:

- The properties of ionic solids are a direct consequence of the *fixed ion positions* and *very strong attractive forces*, which create a high lattice energy. Thus, ionic solids typically have high melting points and low electrical conductivities.
- When a large quantity of heat is supplied and the ions gain enough kinetic energy to break free of their positions, the solid melts and the mobile ions conduct a current.
- Ionic compounds are hard because only a strong external force can change the relative positions of the huge number of ions attracting one another. If enough force is applied to move them, ions of like charge are brought near each other, and their repulsions crack the crystal (see Figure 9.10).

Ionic solids often adopt cubic closest packed crystal structures. Let's consider two examples with a 1/1 ratio of ions and then two with a 2/1 (or 1/2) ratio:

1. The *sodium chloride structure* is found in many ionic compounds, including most alkali (Group 1) halides and hydrides, alkaline earth (Group 2) oxides and sulfides, and several transition metal oxides and sulfides. To visualize this structure, imagine Cl[−] anions and Na⁺ cations in separate, face-centered cubic arrays. Now picture the two arrays penetrating each other, the smaller Na⁺ ions ending up in the holes between the larger Cl[−] ions (Figure 12.33A). Thus, each Na⁺ is surrounded by six Cl[−], and vice versa (coordination number = 6). Figure 12.33B is a space-filling depiction of the unit cell: four Cl[−] [(8 × $\frac{1}{8}$) + (6 × $\frac{1}{2}$) = 4 Cl[−]] and four Na⁺ [(12 × $\frac{1}{4}$) + 1 in the center = 4 Na⁺] give a 1/1 ion ratio.

2. The *zinc blende (ZnS) structure* can be pictured as two face-centered cubic arrays, one of Zn²⁺ ions (gray) and the other of S^{2−} ions (yellow), penetrating each other such that each ion is tetrahedrally surrounded by four of the other ions (coordination number = 4) (Figure 12.34). There are four [(8 × $\frac{1}{8}$) + (6 × $\frac{1}{2}$) = 4] S^{2−} ions and four Zn²⁺ ions for a 1/1 ion ratio. Many other compounds, including AgI, CdS, and the copper(I) halides, adopt the zinc blende structure.

Figure 12.33 The sodium chloride structure. **A**, Expanded view. **B**, Space-filling depiction of the NaCl unit cell.

Figure 12.34 The zinc blende structure. **A**, Expanded view (with bonds shown for clarity). **B**, The unit cell is expanded a bit to show interior ions.

3. The *fluorite* (CaF_2) structure is common among salts with a 1/2 cation/anion ratio that have relatively large cations and small anions, such as SrF_2 and BaCl_2 . In CaF_2 , the unit cell is a face-centered cubic array of Ca^{2+} ions with F^- ions occupying *all* eight available holes (Figure 12.35). This results in a $\text{Ca}^{2+}/\text{F}^-$ ratio of 4/8, or 1/2.

Figure 12.35 The fluorite structure. **A**, Expanded view (with bonds shown for clarity). **B**, The unit cell is expanded a bit to show interior ions.

4. The *antifluorite* structure is common in compounds with a 2/1 cation/anion ratio and a relatively large anion (such as K_2S). The ion arrangement is the opposite of that in the fluorite structure: the cations occupy all eight holes formed by the cubic closest packing of the anions.

Metallic Solids Most metallic elements crystallize in one of the two closest packed structures (Figure 12.36). In contrast to the weak dispersion forces in atomic solids, powerful metallic bonding forces hold atoms together in **metallic solids**:

- The properties of metals—high electrical and thermal conductivity, luster, and malleability—result from their delocalized electrons (Section 9.6).

Figure 12.36 Crystal structures of metals. **A**, Copper adopts cubic closest packing. **B**, Magnesium adopts hexagonal closest packing.

- Melting points and hardnesses are related to the packing efficiency and number of valence electrons. For example, Group 2 metals are harder and melt higher than Group 1 metals (see Figure 9.27), because the Group 2 metals have twice as many delocalized valence electrons.

Network Covalent Solids Strong covalent bonds link the atoms together in a **network covalent solid**; thus, separate particles are not present. These substances adopt a variety of crystal structures depending on the details of their bonding.

As a consequence of strong bonding, all network covalent solids have extremely high melting and boiling points, but their conductivity and hardness vary. Two examples with the same composition but strikingly different properties are the two common crystalline forms of elemental carbon, graphite and diamond:

- *Graphite* occurs as stacked flat sheets of hexagonal carbon rings with a strong σ -bond framework and delocalized π bonds, reminiscent of benzene; the arrangement looks like chicken wire or honeycomb. Whereas the π -bonding electrons of benzene are delocalized over one ring, those of graphite are delocalized over the entire sheet. Thus, graphite conducts electricity well—it is a common electrode material—but only in the plane of the sheets. The sheets interact via dispersion forces, and impurities, such as O_2 , between the sheets allow them to slide past each other, which explains why graphite is soft and used as a lubricant.
- *Diamond* adopts a face-centered cubic unit cell, with each C tetrahedrally bonded to four others in an endless array. Throughout the crystal, strong single bonds make diamond the hardest natural substance known. Like most network covalent solids, diamond does not conduct electricity because the bonding electrons are localized.

These properties are compared in Table 12.6.

Table 12.6 | Comparison of the Properties of Diamond and Graphite

Property	Graphite		Diamond	
Density (g/cm^3)	2.27		3.51	
Hardness	<1 (very soft)		10 (hardest)	
Melting point (K)	4100		4100	
Color	Shiny black		Colorless transparent	
Electrical conductivity	High (along sheet)		None	
$\Delta H_{\text{rxn}}^\circ$ for combustion (kJ/mol)	−393.5		−395.4	
ΔH_f° (kJ/mol)	0 (standard state)		1.90	

The most important network covalent solids are the *silicates*, which consist of extended arrays of covalently bonded silicon and oxygen atoms. Quartz (SiO_2) is a common example. We'll discuss silicates, which form the structure of clays, rocks, and many minerals, when we consider the chemistry of silicon in Chapter 14.

Amorphous Solids

Amorphous solids are noncrystalline. Many have small, somewhat ordered regions interspersed among large, disordered regions. Charcoal, rubber, and glass are examples.

The process that forms quartz glass is typical of many amorphous solids. Crystalline quartz (SiO_2), which adopts cubic closest packing, is melted and the viscous liquid is cooled rapidly to prevent it from recrystallizing. The chains of Si and O atoms cannot orient themselves quickly enough, so they solidify in a distorted jumble containing gaps and misaligned rows (Figure 12.37). The absence of regularity confers some properties of a liquid; in fact, glasses are sometimes referred to as *supercooled liquids*.

Bonding in Solids: Molecular Orbital Band Theory

Chapter 9 introduced a qualitative model of metallic bonding, with metal ions submerged in a “sea” of delocalized valence electrons. Molecular orbital (MO) theory offers a more quantitative, and therefore more useful, model called **band theory**. We’ll focus on bonding in metals and the resulting conductivity of metals, metalloids, and nonmetals.

Formation of Valence and Conduction Bands Recall from Section 11.3 that, when two atoms form a diatomic molecule, their atomic orbitals (AOs) combine to form an equal number of molecular orbitals (MOs). Figure 12.38 shows the formation of MOs in lithium. To form Li_2 , four valence orbitals (one $2s$ and three $2p$) of each Li atom combine to form eight MOs, four bonding and four antibonding. The order of MOs shows mixing of the $2s$ and $2p$ AOs (Figure 11.21B). Two more Li atoms form Li_4 , a slightly larger aggregate, with 16 delocalized MOs. As more Li atoms join the cluster, more MOs are created, and their energy levels lie closer and closer together. Extending this process to 7 g (1 mol) of lithium results in 6×10^{23} Li atoms (Li_{N_A}) combining to form an extremely large number ($4 \times \text{Avogadro's number}$) of delocalized MOs. *The energies of the MOs are so close that they form a continuum, or band, of MOs.*

The lower energy MOs are occupied by the $2s^1$ valence electrons and make up the **valence band**. The empty MOs that are higher in energy make up the **conduction band**. In Li metal, the valence band is derived from the $2s$ AOs, and the conduction band is derived from $2s$ and mostly $2p$ AOs. In Li_2 , two valence electrons fill the lowest energy bonding MO and leave the antibonding MO empty. In Li metal, 1 mol of valence electrons fills the valence band and leaves the conduction band empty.

How Band Theory Explains Metallic Properties The key to understanding the properties of metals is that *the valence and conduction bands are contiguous*; that is, the highest level of one touches the lowest of the other. This means that, given an infinitesimal quantity of energy, electrons jump from the filled valence band to the unfilled conduction band: the electrons are completely delocalized and free to move.

- **Electrical conductivity.** Metals conduct electricity so well because an applied field easily excites the highest energy valence electrons into empty conduction orbitals, allowing them to move through the sample.

Figure 12.37 Crystalline and amorphous silicon dioxide. **A**, Cristobalite, a crystalline form of silica (SiO_2), shows cubic closest packing. **B**, Quartz glass is amorphous with a generally disordered structure.

Figure 12.38 The band of molecular orbitals in lithium metal.

- *Luster.* With so many closely spaced levels available, electrons absorb and release photons of many frequencies as they move between the valence and conduction bands.
- *Malleability.* Under an applied force, layers of positive metal ions move past each other, always protected from mutual repulsions by the delocalized electrons.
- *Thermal conductivity.* When a metal wire is heated, the highest energy electrons are excited and their extra energy is transferred as kinetic energy along the wire's length.

Conductivity of Solids and the Size of the Energy Gap Like metal atoms, large numbers of nonmetal and metalloid atoms can form bands of MOs. Band theory explains differences in electrical conductivity and the effect of temperature among these three classes of substances in terms of the presence of an energy gap between their valence and conduction bands (Figure 12.39):

1. *Conductors (metals).* The valence and conduction bands of a **conductor** have *no energy gap* between them, so electrons flow when a tiny electrical potential difference is applied. When the temperature is raised, greater random motion of the atoms hinders electron movement: conductivity *decreases* when a metal is heated.
2. *Semiconductors (metalloids).* In a **semiconductor**, a *small energy gap* exists between the valence and conduction bands. Thermally excited electrons can cross the gap, allowing a small current to flow: in contrast to a conductor, conductivity *increases* when a semiconductor is heated.
3. *Insulators (nonmetals).* In an **insulator**, a *large energy gap* exists between the bands: no current is observed even when the substance is heated.

Figure 12.39 Electrical conductivity in a conductor, semiconductor, and insulator.

Another type of electrical conductivity, called **superconductivity**, has been the focus of intensive research for the past few decades. When metals conduct at ordinary temperatures, moving electrons collide with vibrating atoms; the reduction in their flow appears as resistive heating and represents a loss of up to 20% of electrical energy as heat.

For many years, to conduct with no energy loss—to superconduct—required minimizing atom movement by cooling with liquid helium (bp = 4 K). Then, in 1986, certain ionic oxides were prepared that superconduct near the boiling point of liquid nitrogen (bp = 77 K), which is significantly less expensive than liquid helium. Like metal conductors, oxide superconductors, such as $\text{YBa}_2\text{Cu}_3\text{O}_7$, have no gap between bands. In 1989, oxides with Bi and Tl instead of Y and Ba were synthesized and found to superconduct at 125 K; and, in 1993, an oxide with Hg, Ba, and Ca, in addition to Cu and O, superconducted at 133 K. Scientists continue to search for substances that superconduct at even higher temperatures and in 2020, a substance composed of H, C and S was found to be superconducting at room temperature under an extremely high pressure. Research in the field continues due to the fascinating possibilities of uses for superconductors. They are part of electromagnets that levitate superfast trains (maglev trains) and that are used in MRI medical imaging machines. Superconductors could transmit electricity with no loss of energy and be part of ultrasmall microchips for ultrafast computers. More research is needed to understand how superconductors work and to unlock their potential.

› Summary of Section 12.6

- › Particles in crystalline solids lie at points that form a structure of repeating unit cells.
- › The three types of unit cells of the cubic system are simple, body-centered, and face-centered. The highest packing efficiency occurs with cubic (face-centered) and hexagonal closest packing.
- › Bond angles and distances in a crystal are determined with x-ray diffraction analysis and scanning tunneling microscopy. These data are used to determine atomic radii.
- › Atomic solids (Group 18) adopt cubic closest packing, with atoms held together by weak dispersion forces.
- › Molecular solids have molecules at the lattice points and often adopt cubic closest packing. Combinations of intermolecular forces (dispersion, dipole-dipole, and H bonding) result in physical properties that vary greatly.
- › Ionic solids crystallize with one ion filling holes in the cubic closest packed array of the other. High melting points and hardness and low conductivity arise from strong ionic attractions.
- › Most metals have a closest packed structure. Their physical properties result from the high packing efficiency and the presence of delocalized electrons.
- › Atoms of network covalent solids are covalently bonded throughout the sample, so these substances have very high melting and boiling points.
- › Amorphous solids have little regularity in their structure.
- › Band theory proposes that atomic orbitals of many atoms combine to form a continuum, or band, of molecular orbitals. Metals are electrical conductors because electrons move freely from the filled (valence) band to the empty (conduction) band. Insulators have a large energy gap between the two portions, and semiconductors have a small gap, which can be bridged by heating.

12.7 ADVANCED MATERIALS

In the last few decades, the exciting field of materials science has applied concepts from solid-state chemistry, physics, and engineering. Objects that were once considered futuristic fantasies have become realities: powerful, ultrafast computers smaller than a cell phone; cars powered by sunlight and made of nonmetallic parts stronger than steel and lighter than aluminum; ultrasmall machines constructed by manipulating individual atoms and molecules. In this section, we briefly discuss some of these remarkable materials.

Electronic Materials

The ideal of a perfectly ordered crystal is attainable only if the crystal is grown very slowly under carefully controlled conditions. When crystals form more rapidly, **crystal defects** inevitably result. Planes of particles are misaligned, particles are out of place or missing entirely, and foreign particles replace those that belong in the lattice. Although defects usually weaken a substance, they can be introduced intentionally to improve materials, giving them increased strength, hardness, or conductivity. Purposely created crystal defects are utilized in modern electronic materials.

Doped Semiconductors By controlling the number of valence electrons through the creation of specific types of crystal defects, chemists and engineers can greatly increase the conductivity of a semiconductor. For example, pure silicon (Group 14) conducts poorly at room temperature because an energy gap separates its filled valence band from its conduction band (Figure 12.40A). Silicon's conductivity can be greatly enhanced by **doping**, intentionally adding small amounts of other elements to increase or decrease the number of valence electrons in the bands.

- *Doping to create an n-type semiconductor: increasing the number of valence electrons.* When Si is doped with phosphorus (or another Group 15 element), P atoms replace Si atoms in some of the lattice sites. Since P has one more valence electron than Si, this additional electron must enter an empty orbital in the conduction band,

Figure 12.40 Crystal structures and band representations of doped semiconductors. **A**, Pure silicon has an energy gap between its valence and conduction bands, which keeps conductivity low at room temperature. **B**, Doping silicon with phosphorus (orange) adds additional valence electrons. **C**, Doping silicon with gallium (orange) removes electrons from the valence band and introduces positive holes.

Figure 12.41 The p-n junction. Placing a p-type semiconductor adjacent to an n-type creates a p-n junction.

Traffic signals in the United States are being converted to LEDs.

Source: Rawf8/iStock/Getty Images

thus bridging the energy gap and increasing conductivity. Such doping creates an *n-type semiconductor*, so called because extra *negative* charges (electrons) are present (Figure 12.40B).

- *Doping to create a p-type semiconductor: decreasing the number of valence electrons.* When Si is doped with gallium (or another Group 13 element), Ga atoms replace Si atoms in some sites (Figure 12.40C). Since Ga has one fewer valence electron than Si, some of the orbitals in the valence band are empty, which creates a positive site. Si electrons can migrate to these empty orbitals, thereby increasing conductivity. Such doping creates a *p-type semiconductor*, so called because the empty orbitals act as positive holes.

In contact with each other, an n-type and a p-type semiconductor form a *p-n junction*. When the negative terminal of a battery is connected to the n-type portion and the positive terminal to the p-type portion, electrons (yellow, *negative spheres*) flow freely in the n-to-p direction, which has the simultaneous effect of moving holes (white, *positive spheres*) in the p-to-n direction (Figure 12.41A). No current flows if the terminals are reversed (Figure 12.41B). Such unidirectional current flow makes a p-n junction act as a *rectifier*, a device that converts alternating current into direct current. A p-n junction in a modern integrated circuit can be made smaller than a square 10 μm on a side.

A modern computer chip the size of a nickel may incorporate millions of p-n junctions in the form of *transistors*. One of the most common types, an n-p-n transistor, is made by sandwiching a p-type portion between two n-type portions to form adjacent p-n junctions. The current flowing through one junction controls the current flowing through the other and results in an amplified signal.

One of the more common types of *solar cell* is, in essence, a p-n junction with an n-type surface exposed to a light source. Light provides the energy to free electrons from the n-type region and accelerate them through an external circuit into the p-type region, thus producing a current.

Another application of p-n junctions is the light-emitting diode (LED). The electrical energy that results when electrons from the n-type portion fall into holes in the p-type portion of the junction is converted to optical energy, with photons of energy equal to the band gap being emitted. The wavelength of the light emitted is determined by the semiconductor used. For example, some red LEDs are made of GaP, whereas some green LEDs are made of GaN. As was discussed in Chapter 6, replacing inefficient incandescent lightbulbs (such as those in traffic signals, *see photo*) with more energy-efficient LEDs can drastically reduce electricity usage.

Liquid Crystals

Incorporated in the membrane of every cell in your body and in the display of every electronic device are **liquid crystals**. These materials flow like liquids but, like crystalline solids, pack with a high degree of order at the molecular level.

Ordering of the Particles Let's examine how particles are ordered in the three physical states and how this affects their properties. Both gases and liquids are *isotropic*—their physical properties are the same in every direction within the phase. For example, the viscosity of a gas or a liquid is the same regardless of direction. Glasses and other amorphous solids are also isotropic because they have no regular lattice structure.

In contrast, crystalline solids have a high degree of order among their particles. The properties of a crystal *do* depend on direction, so a crystal is *anisotropic*. The facets in a cut diamond, for instance, arise because the crystal cracks in one direction more easily than in another. Liquid crystals are anisotropic with respect to several physical properties, including electrical and optical properties, which differ with direction through the phase.

Molecular Characteristics Liquid crystal phases consist of individual molecules with two characteristics: (1) a long, cylindrical shape and (2) a structure that fosters intermolecular attractions but inhibits perfect crystalline packing. Molecules that form liquid crystal phases have rodlike shapes and certain groups—in the cases shown in Figure 12.42, flat, benzene-like ring systems—that keep the molecules extended and make it possible for them to arrange themselves in an orderly fashion. Many of these molecules also have polarity associated with the long molecular axis. A strong electric field can orient these polar molecules like compass needles in a magnetic field.

The viscosity of a liquid crystal phase is lowest in the direction parallel to the long axis. Like moistened microscope slides, it is easier for the molecules to slide along each other (because the total attractive force remains the same), than it is for them to pull apart from each other sideways. As a result, the molecules tend to align while the phase flows.

Controlling Conditions to Form Phases Liquid crystal phases can arise in two general ways, and, sometimes, either way can occur in the same substance:

1. *Thermotropic phases* develop as a result of a change in temperature. As a crystalline solid is heated, the molecules leave their lattice sites, but the intermolecular interactions are still strong enough to keep the molecules aligned with each other

Figure 12.42 Structures of two typical molecules that form liquid crystal phases. Note the long, extended shapes and the regions of high (red) and low (blue) electron density.

along their long axes. Further heating provides enough kinetic energy for the molecules to become disordered, as in a normal liquid. Pure substances exhibit liquid crystal behavior over a relatively small temperature range, usually $<1^{\circ}\text{C}$ to as much as 10°C , but mixing phases of two or more substances can greatly extend this range. For this reason, the liquid crystal phases used within display devices, as well as those within cell membranes, consist of mixtures of molecules.

2. *Lyotropic phases* occur in solution as the result of changes in concentration, but the conditions for forming such a phase vary for different substances. For example, when purified, some biomolecules that exist in cell membranes form lyotropic phases in water at the temperature that occurs within the organism. At the other extreme, Kevlar, a fiber used in bulletproof vests and high-performance sports equipment, forms a lyotropic phase in concentrated H_2SO_4 solution.

In some cases, a substance that forms a given liquid crystal phase under one set of conditions forms other phases under different conditions. Thus, a given thermotropic liquid crystal substance can pass from disordered liquid through a series of distinct liquid crystal phases to an ordered crystal through a decrease in temperature. A lyotropic substance can undergo similar changes through an increase in concentration.

Types of Order in Liquid Crystal Phases Molecules that form liquid crystal phases can exhibit various types of order. Three common types are nematic, cholesteric, and smectic:

1. In a *nematic phase*, the molecules lie in the same direction but their ends are not aligned, much like a school of fish swimming in synchrony (Figure 12.43A). The nematic phase is the least ordered type of liquid crystal phases.
2. In a *cholesteric phase*, which is somewhat more ordered, the molecules lie in layers that each exhibit nematic-type ordering. Rather than lying in parallel fashion, however, each layer is rotated by a fixed angle with respect to the next layer to give a helical (corkscrew) arrangement. A cholesteric phase is often called a *twisted nematic phase* (Figure 12.43B).
3. In a *smectic phase*, which is the most ordered, the molecules lie parallel to each other, with their ends aligned, in layers that are stacked directly over each other (Figure 12.43C). The long molecular axis has a well-defined angle (shown in the figure as 90°) with respect to the plane of the layer. The molecules in Figure 12.42 form nematic or smectic phases.

Applications of Liquid Crystals The ability to control the orientation of the molecules in a liquid crystal allows us to produce materials with high strength or unique optical properties:

1. *High-strength applications* involve the use of extremely long molecules called *polymers*. While in a thermotropic liquid crystal phase and during their flow through the processing equipment, these molecules become highly aligned, like the fibers in

Figure 12.43 The three common types of ordering in liquid crystal phases.

wood. Cooling solidifies them into fibers, rods, and sheets that can be shaped into materials with superior mechanical properties. Sporting equipment, supersonic aircraft parts, and the sails used in the America's Cup races are fabricated from these polymeric materials. (We discuss the structure and physical behavior of polymers later in this section and their synthesis in Chapter 15.)

2. *Optical applications* include the liquid crystal displays (LCDs) used in countless devices, such as watches, calculators, cell phones, and tablets. All depend on *changes in molecular orientation in an electric field*. Figure 12.44 shows a small portion of a wristwatch LCD. Layers of nematic phases are sandwiched between thin glass plates that incorporate transparent electrodes. The long molecular axes lie parallel to the plane of the plates. The distance between plates (6–8 μm) allows the molecular axes within each succeeding layer to twist just enough for the molecular orientation at the bottom plate to be 90° from that at the top plate. Above and below this “sandwich” are thin polarizing filters that allow light waves oriented in only one direction to pass through. The filters are placed in a “crossed” arrangement so that light passing through the top filter must twist 90° to pass through the bottom filter. This whole grouping of filters, plates, and liquid crystal phase lies on a mirror.

A current generated by the watch battery controls the orientation of the molecules. With the current on in one region of the display, the molecules become oriented *toward* the field, and thus block the light from passing through to the bottom filter, so that region appears dark. With the current off in another region, light passes through the molecules and bottom filter to the mirror and back again, so that region appears bright.

Cholesteric liquid crystals are used in applications that involve color changes with temperature. The twisted molecular orientation “unwinds” with heating, and the extent of the unwinding determines the color. Liquid crystal thermometers include a mixture of substances to widen their range of temperatures. Newer uses include “mapping” the area of a tumor, detecting faulty connections in electronic circuit boards, and nondestructive testing of materials under stress.

Ceramic Materials

First developed by Stone Age people, **ceramics** are nonmetallic, nonpolymeric solids hardened by high temperature. Clay ceramics consist of silicate microcrystals suspended in a glassy cementing medium. In “firing” a ceramic pot, for example, a kiln heats the object, made of an aluminosilicate clay, such as kaolinite, to 1500°C and the clay loses water:

During the heating process, the structure rearranges to an extended network of Si-centered and Al-centered tetrahedra of O atoms (Section 14.6).

Bricks, porcelain, glazes, and other clay ceramics are hard and resistant to heat and chemicals. Today's high-tech ceramics have these characteristics in addition to superior electrical and magnetic properties (Table 12.7). As just one example, consider

Table 12.7 | Some Uses of Modern Ceramics and Ceramic Mixtures

Ceramic	Applications
SiC, Si ₃ N ₄ , TiB ₂ , Al ₂ O ₃	Whiskers (fibers) to strengthen Al and other ceramics
Si ₃ N ₄	Car engine parts, turbine rotors for “turbo” cars, electronic sensor units
Si ₃ N ₄ , BN, Al ₂ O ₃	Support or layering materials (as insulators) in electronic microchips
SiC, Si ₃ N ₄ , TiB ₂ , ZrO ₂ , Al ₂ O ₃ , BN	Cutting tools, edge sharpeners (as coatings and whole devices), scissors, surgical tools, industrial “diamond”
BN, SiC	Armor-plating reinforcement fibers (as in Kevlar composites)
ZrO ₂ , Al ₂ O ₃	Surgical implants (hip and knee joints)

Figure 12.44 A liquid crystal display (LCD). A close-up of the “2” on a wristwatch LCD reveals two polarizers sandwiching two glass plates, which sandwich a liquid crystal (LC) layer, all lying on a mirror. When light waves enter the first polarizer, waves oriented in one direction emerge to enter the LC layer. Enlarging a dark region (*top blow-up*) shows the LC molecules aligned, keeping light waves from passing through; thus, the viewer sees no light. Enlarging a bright region (*bottom blow-up*) shows the LC molecules rotating the plane of the light waves, which can then pass through and reach the viewer.

the unusual electrical behavior of certain zinc oxide (ZnO) composites. Ordinarily a semiconductor, ZnO can be doped so that it becomes a conductor. Imbedding particles of the doped oxide into an insulating ceramic produces a variable resistor: at low voltage, the material conducts poorly, but, at high voltage, it conducts well. The changeover voltage can be “preset” by controlling the size of the ZnO particles and the thickness of the insulating medium.

Ceramic Structures and Uses Among the important modern ceramics are silicon carbide (SiC) and nitride (Si_3N_4), boron nitride (BN), and the superconducting oxides. Their structures are shown in Figure 12.45.

1. *Silicon carbide* has a diamond-like structure (see Figure 12.45A). Network covalent bonding gives this material great strength. It is made into thin fibers, called *whiskers*, to reinforce other ceramics and prevent cracking in a composite structure, much like steel rods reinforcing concrete.

2. *Silicon nitride* is virtually inert chemically, retains its strength and wear resistance for extended periods above 1000°C , is dense and hard, and acts as an electrical insulator. Many automakers are testing it in high-efficiency car and truck engines because of its low weight, tolerance of high operating temperatures, and little need for lubrication.

3. *BN ceramics* exist in two structures, analogous to the common crystalline forms of carbon. In the graphite-like form, BN has extraordinary properties as an electrical insulator. At high temperature and very high pressure (1800°C and 8.5×10^4 atm), BN converts to a diamond-like structure (see Figure 12.45B), which is extremely hard and durable. Both forms are virtually invisible to radar.

4. *Superconducting oxides* often contain copper in an unusual oxidation state. In $\text{YBa}_2\text{Cu}_3\text{O}_7$ (see Figure 12.45C), for instance, assuming oxidation states of +3 for Y, +2 for Ba, and -2 for O, the three Cu atoms have a total oxidation state of +7. This is allocated as $\text{Cu(II)}_2\text{Cu(III)}$, with one Cu in the unusual +3 state. X-ray diffraction analysis indicates that a distortion in the structure makes four of the oxide ions unusually close to the Y^{3+} ion, which aligns the Cu ions into chains within the crystal. It is thought that a specific half-filled $3d$ orbital in Cu oriented toward a neighboring O^{2-} ion may be associated with superconductivity.

Polymeric Materials

A **polymer** (Greek, “many parts”) is an extremely large molecule, or **macromolecule**, consisting of a covalently linked chain of smaller molecules, called **monomers** (Greek, “one part”). The monomer is the *repeat unit* of the polymer, and a polymer may have hundreds to hundreds of thousands of repeat units. Many types of monomers give polymers the complete repertoire of intermolecular forces.

- *Synthetic* polymers are created in the laboratory.
- *Natural* polymers (or *biopolymers*) are created within organisms.

In this section, we examine the physical nature of synthetic polymers and explore the role of intermolecular forces in their properties and uses. In Chapter 15, we'll examine the types of monomers, the preparation of synthetic polymers, and the monomers, structures, and functions of some biopolymers.

Dimensions of a Polymer Chain Polymers differ from smaller molecules in terms of molar mass, chain length, shape, and size. We'll discuss these, using polyethylene, by far the most common synthetic polymer, as an example.

1. *Polymer mass.* The molar mass of a polymer chain ($\mathcal{M}_{\text{polymer}}$ in g/mol, often referred to as the *molecular weight*) depends on the molar mass of the repeat unit ($\mathcal{M}_{\text{repeat}}$) and the **degree of polymerization** (n), the number of repeat units in the chain:

$$\mathcal{M}_{\text{polymer}} = \mathcal{M}_{\text{repeat}} \times n$$

For example, the molar mass of the ethylene repeat unit ($\text{—CH}_2\text{—CH}_2\text{—}$) is 28 g/mol. If an individual polyethylene chain in a plastic grocery bag has a degree of polymerization of 7100, the molar mass of that chain is

$$\mathcal{M}_{\text{polymer}} = \mathcal{M}_{\text{repeat}} \times n = (28 \text{ g/mol})(7.1 \times 10^3) = 2.0 \times 10^5 \text{ g/mol}$$

Table 12.8 shows some other examples.

Table 12.8 | Molar Masses of Some Common Polymers

Name	$\mathcal{M}_{\text{polymer}}$ (g/mol)	n	Uses
Acrylates	2×10^5	2×10^3	Rugs, carpets
Polyamide (nylons)	1.5×10^4	1.2×10^2	Tires, fishing line
Polycarbonate	1×10^5	4×10^2	Compact discs
Polyethylene	3×10^5	1×10^4	Grocery bags
Polyethylene (ultrahigh molecular weight)	5×10^6	2×10^5	Hip joints
Poly(ethylene terephthalate)	2×10^4	1×10^2	Soda bottles
Polystyrene	3×10^5	3×10^3	Packing, coffee cups
Poly(vinyl chloride)	1×10^5	1.5×10^3	Plumbing

However, even though the monomer repeat unit in any given chain has the same molar mass, the degree of polymerization often varies considerably from chain to chain. Thus, *a sample of a synthetic polymer has a distribution of chain lengths and molar masses*. Polymer chemists use various definitions of the *average* molar mass, and a common one is the *number-average molar mass*, $\mathcal{M}_n$:

$$\mathcal{M}_n = \frac{\text{total mass of all chains}}{\text{number of moles of chains}}$$

If the number-average molar mass of the polyethylene in grocery bags is, for example, 1.6×10^5 g/mol, the chains may vary in molar mass from about 7.0×10^4 to 3.0×10^5 g/mol.

2. *Polymer chain length.* The long axis of a polymer chain is called its *backbone*. The length of an *extended* backbone is simply the number of repeat units (degree of

Figure 12.46 The random-coil shape of a polymer chain. Note the random coiling of the chain's carbon atoms (*black*). Sections of several nearby chains (*red, green, and yellow*) are entangled with this chain, kept near one another by dispersion forces. In reality, entangling chains fill any gaps shown here.

polymerization, n) times the length of each repeat unit (l_0). For instance, the length of an ethylene repeat unit is about 250 pm, so the extended length of our grocery-bag polyethylene chain is

$$\text{Length of extended chain} = n \times l_0 = (7.1 \times 10^3)(2.5 \times 10^2 \text{ pm}) = 1.8 \times 10^6 \text{ pm}$$

Comparing this length with the thickness of the chain, which is about 40 pm, shows the threadlike nature of the extended chain (length about 50,000 times width).

3. Coiled shape and size. A polymer molecule, however, whether pure or in solution, doesn't exist as an extended chain. In principle, the shape of the molecule arises from free rotation around all the single bonds. Thus, as each repeat unit rotates randomly, the chain continuously changes direction, turning back on itself many times and eventually arriving at the **random coil** shape that most polymers adopt (Figure 12.46). In reality, rotation is not completely free because intermolecular forces between chain portions, between different chains, and/or between chain and solvent have significant effects on the actual shape of a polymer chain.

The size of the coiled chain is expressed by its **radius of gyration**, R_g , the average distance from the center of mass of the molecule to the outer edge of the coil (see Figure 12.46). Even though R_g is reported as a single value for a given polymer, it represents an average value for many chains. The mathematical expression for the radius of gyration includes the length of each repeat unit and the degree of polymerization:*

$$R_g = \sqrt{\frac{nl_0^2}{6}}$$

As expected, the radius of gyration increases with the degree of polymerization, and thus with the molar mass as well. Light-scattering measurements correlate with these calculated results, so for many polymers the radius of gyration can be determined experimentally.

*The mathematical derivation of R_g is beyond the scope of this text, but it is analogous to the two-dimensional "walk of the drunken sailor." With each step, the sailor stumbles in random directions and, given enough time, ends up very close to the starting position. The radius of gyration quantifies how far the end of the polymer chain (the sailor) has gone from the origin.

Figure 12.47 The semi-crystallinity of a polymer chain. Several crystalline regions (darker color) have randomly coiled regions between them. Crystalline regions from nearby chains (red and yellow) align with those in the main chain.

For our grocery-bag polyethylene chain, we have

$$R_g = \sqrt{\frac{nl_0^2}{6}} = \sqrt{\frac{(7.1 \times 10^3)(2.5 \times 10^2 \text{ pm})^2}{6}} = 8.6 \times 10^3 \text{ pm}$$

Doubling the radius gives a diameter of 1.7×10^4 pm for the coiled chain, less than one-hundredth the length of the extended chain!

Polymer Crystallinity A sample of a given polymer is not just a disorderly jumble of chains. If the molecular structure allows neighboring chains to pack together and if the chemical groups lead to favorable dipole-dipole, H bonding, and/or dispersion forces, portions of the chains can align regularly and exhibit crystallinity.

However, the crystallinity of a polymer is very different from the crystal structures we discussed earlier. In those structures, the orderly array extends over many atoms or molecules, and the unit cell includes at least one atom or molecule. In contrast, the orderly regions of a polymer rarely involve even one whole molecule (Figure 12.47). At best, a polymer is *semicrystalline*, because parts of the molecule align with parts of neighboring molecules (or with other parts of the same chain) while most of the chain remains as a random coil.

Viscosity of Pure and Dissolved Polymers Some of the most important uses of polymers arise from their ability to change the viscosity of a solvent in which they are dissolved and to undergo temperature-dependent changes in their own viscosity.

1. *Dissolved polymers.* When an appreciable amount of polymer (approximately 5–15 mass %) dissolves, the viscosity of the solution is much higher than that of the pure solvent. In fact, polymers are added to increase the viscosity of many common materials, such as motor oil, paint, and salad dressing. As the random coil of a polymer moves through a solution, solvent molecules are attracted to it through intermolecular forces (Figure 12.48). Thus, as the solution flows, the polymer coil drags along solvent molecules that are interacting with other solvent molecules and other coils, and flow is reduced. Increasing the polymer concentration increases the viscosity because coils are more likely to become entangled.

Viscosity is a property of a particular polymer-solvent pair at a given temperature. The size (radius of gyration) of a random coil in solution increases with molar mass, and so does the viscosity. To improve polymer manufacture, chemists have developed

Figure 12.48 The viscosity of a polymer in aqueous solution. A section of a poly(ethylene oxide) chain (*left panel*) forms H bonds between the lone pairs of the chain's O atoms and the H atoms of water molecules. A polymer chain (*blue and red coiled rod, center panel*) forms many H bonds with water molecules that allow the chain to interact with other chains. As the concentration of polymer increases (*three right panels*), the viscosity of the solution increases.

equations to predict the viscosity of polymers of different molar masses in a variety of solvents (see Problem 12.146).

2. Pure polymers. Intermolecular forces also play a major role in the flow of a pure polymer. At temperatures high enough to melt them, many polymers exist as viscous liquids, flowing more like honey than water. The forces between the chains, as well as the entangling of chains, hinder the flow. As the temperature decreases, the intermolecular attractions exert a greater effect, and the eventual result is a rigid solid. If the chains don't crystallize, the resulting material is called a *polymer glass*. The transition from a liquid to a glass occurs over a narrow temperature range (10–20°C) for a given polymer; the temperature at the midpoint of the range is called the *glass transition temperature*, T_g . Like window glass, many polymer glasses are transparent, including polystyrene in drinking cups and polycarbonate in eyeglass lenses.

Plasticity of Polymers The flow-related properties of polymers give rise to their familiar **plastic** mechanical behavior. The word *plastic* refers to a material that, when deformed, retains its new shape; in contrast, when an *elastic* object is deformed, it returns to its original shape. Many polymers can be deformed (stretched, bent, twisted) when warm and retain their deformed shape when cooled. In this way, they are made into milk bottles, car parts, and countless other everyday objects.

Molecular Architecture of Polymers A polymer's architecture—its overall spatial layout and molecular structure—is crucial to its properties. In addition to linear chains, more complex architectures arise through branching and crosslinking:

1. Branches are smaller chains appended to a polymer backbone. As the number of branches increases, the chains cannot pack as well, so the degree of crystallinity decreases and the polymer is less rigid. A small amount of branching occurs as a side

reaction in the preparation of high-density polyethylene (HDPE). It is still largely linear and rigid enough for use in milk containers. In contrast, much more branching is intentionally induced to prepare low-density polyethylene (LDPE). The chains cannot pack well, so crystallinity is low. This polymer is used in flexible, transparent food storage bags.

Dendrimers are prepared from monomers with three or more attachment points, so each monomer forms branches. In essence, then, dendrimers have no backbone and consist only of branches. As a dendrimer grows, it has a constantly increasing number of branches and an incredibly large number of end groups at its outer edge. Chemists use dendrimers to bind one polymer to another to create films and fibers and to deliver drugs in medical applications.

2. **Crosslinks** can be thought of as branches that link one chain to another. The extent of crosslinking leads to remarkable differences in properties. A small degree of crosslinking often yields a *thermoplastic* polymer, one that still flows at high temperatures. A solid thermoplastic polymer can be melted and then cooled to have a different shape upon returning to the solid phase. This property allows this type of polymer to be recycled and makes it a good choice for use in 3-D printing. But, as the extent of crosslinking increases, a thermoplastic polymer is transformed into a *thermoset* polymer, one that can no longer flow because it has become a single network; once a thermoset polymer is shaped, it cannot be melted and remolded. Below their glass transition temperatures, some thermosets are extremely rigid and strong, making them ideal as matrix materials in high-strength composites (*see photo*).

Above their glass transition temperatures, many thermosets become **elastomers**, polymers that can be stretched and immediately spring back to their initial shapes when released, like a trampoline or a rubber band. When you stretch a rubber band, individual polymer chains flow for only a short distance before the connectivity of the network returns them to their original positions. Table 12.9 is a list of some elastomers.

Table 12.9 | Some Common Elastomers

Name	T_g (°C)	Uses
Poly(dimethyl siloxane)	−123	Breast implants
Polybutadiene	−106	Rubber bands
Polyisoprene	−65	Surgical gloves
Polychloroprene (neoprene)	−43	Footwear, medical tubing

Impact of Monomer Sequence Differences in monomer sequences influence polymer properties as well. A *homopolymer* consists of one type of monomer (A—A—A—A—A—...), whereas a **copolymer** consists of two or more types. The simplest copolymer is called an *AB block copolymer* because a chain (block) of monomer A and a chain of monomer B are linked at one point:

If the intermolecular forces between the A and B portions of the chain are weaker than those between different regions within each portion, the A and B portions form their own random coils. This ability makes AB block copolymers ideal *adhesives* for joining two polymer surfaces covalently. An ABA block copolymer has A chains linked at each end of a B chain:

Some of these block copolymers act as *thermoplastic elastomers*, materials shaped at high temperature that become elastomers at room temperature; many are used in the modern footwear industry.

Silicone polymers are described in Chapter 14, and organic reactions that form polymer chains from monomers are examined in Chapter 15.

Nanotechnology: Designing Materials Atom by Atom

Nanotechnology is the science and engineering of nanoscale systems, whose sizes range from 1 to 100 nm. (Recall that 1 nm is 10^{-9} m—about one-billionth the width of your dorm-room desk or one-millionth the width of your pen tip. A nanometer is to a meter as a marble is to Earth!) Nanotechnology joins scientists from physics, materials science, chemistry, biology, environmental science, medicine, and many branches of engineering.

Nanoscale materials behave neither like atoms, which are smaller (about 1×10^{-1} nm), nor like crystals, which are larger (at least 1×10^5 nm). The different behavior is due to a surface area that is similar to their interior volume—for example, a 5-nm particle has about half of its atoms on its surface. Cut a piece of ordinary aluminum foil into pieces just large enough to see with a light microscope and they still behave like the original piece. But, if you could cut the original piece into 20–30-nm pieces, they would explode. Indeed, aluminum nanoparticles are used in fireworks and propellants.

As so often happens in science, a technological advance allowed this new field to blossom. Nanotechnologists can use the scanning tunneling microscope (see Tools of the Laboratory in Section 12.6) and the similar scanning probe and atomic force microscopes to examine the chemical and physical properties of nanostructures and build them up, in many cases, atom by atom.

Two features of nanoscale engineering occur routinely in nature:

1. *Self-assembly* is the ability of smaller, simpler parts to organize themselves into a larger, more complex whole. On the molecular scale, *self-assembly* refers to atoms or small molecules aggregating through intermolecular forces. Oppositely charged regions on two such particles make contact to form a larger particle, which in turn aggregates with another to form a still larger one.
2. *Controlled orientation* is the positioning of two molecules near each other long enough for intermolecular forces to result in a change, often a bond breaking or forming. All enzymes function this way.

Because this field is changing so fast, we can only provide a glimpse of a few exciting research directions in nanotechnology.

Nanoscale Optical Materials *Quantum dots* are nanoparticles of a semiconducting material, such as gallium arsenide (GaAs) or gallium selenide (GaSe), that are smaller than 10 nm. Rather than having a band of energy levels, the dot has discrete energy levels, much like a single atom. As in atoms, the energy levels can be studied with spectroscopy; unlike atoms, quantum dots can be modified chemically. When high-energy (short-wavelength) UV light irradiates a suspension of quantum dots, they become excited and emit radiation of lower energy (longer wavelength). Most importantly, the emitted wavelengths depend on the size of the dots: the larger the particles, the longer the wavelength emitted. Thus, the color of the emitted light can be “tuned” by varying the dimensions of the nanoparticles (Figure 12.49). One use for quantum dots is the imaging of specific cells. The dot is encapsulated in a coating and then bonded to a particular protein used by a target organ. The cells in the target incorporate the protein, along with its attached quantum dot, and the location of the protein is viewed spectroscopically. Quantum dots are brighter than the dyes traditionally used for this purpose. Quantum dots are also being used in the screen display of some television models (called QLED TVs) and are being investigated for use in the new field of quantum computing.

Figure 12.49 The colors of quantum dots. The smaller the dots, the shorter the emitted wavelengths. The diameters of the dots increase from 2 nm on the far left to 7 nm on the far right.

Nanostructured Materials *Nanostructuring*, the construction of bulk materials from nanoscale building blocks, increases strength, ductility, plasticity, and many other properties. The resulting *nanocomposites* behave as liquid magnets, ductile cements, conducting elastomers, and many other unique materials.

One example mimics a familiar natural material. Bones are natural nanocomposites of hydroxyapatite (a type of calcium phosphate) and other minerals. Synthetic nanocrystalline hydroxyapatite has weight-bearing properties identical to bone and can be formed into a framework into which natural bone tissue can grow to heal a fracture. Another material, called a *ferrofluid*, consists of magnetic nanoparticles (usually magnetite, Fe_3O_4) dispersed in a viscous fluid. When placed in a magnetic field, the particles align to conform to the shape of the field (Figure 12.50). Ferrofluids find uses in automobile shock absorbers, magnetic plastics, audio speakers, computer hard drives, high-vacuum valves, and many other devices.

High-Surface-Area Materials Carbon nanotubes have remarkable mechanical and electrical properties. But a possible future application for them is in storing H_2 gas for hydrogen-powered vehicles. Currently, H_2 is stored in metal cylinders at high pressures (>70 atm). Porous solids, such as carbon nanotubes, can store the same amount of gas at much lower pressures because they have surface areas of $4500 \text{ m}^2/\text{g}$ —about four football fields per gram of material! Thus, a medium-sized container of nanotubes could store a large amount of H_2 fuel under conditions safe enough for a family car. Other high-surface-area materials being developed are porous membranes for water purification or batteries and multilayer films that incorporate photosynthetic molecules for high-efficiency solar cells.

Nanomedicine In the new field of nanomedicine, researchers are investigating ways to utilize nanomaterials in the detection and treatment of illnesses and diseases such as diabetes, cancer, and various infectious diseases. For example, a molecule-specific biosensor that uses color changes in gold nanoparticles to detect as little as 10^{-14} mol of DNA has been developed. Such biosensors could circulate freely in the bloodstream to measure levels of specific disease-related molecules, deliver drugs to individual cells, and even alter individual genes. Other research has shown that light-activated nanoparticles can kill cancer cells. The use of nanotechnology in medicine is expected to have a significant impact as it advances.

Figure 12.50 The magnetic behavior of a ferrofluid. Nanoparticles of magnetite (Fe_3O_4) dispersed in a viscous fluid under the influence of a magnetic field.

› Summary of Section 12.7

- › Doping increases the conductivity of semiconductors and is essential to modern electronic materials. Doping silicon with Group 15 atoms introduces negative sites (creating an n-type semiconductor) by adding valence electrons to the conduction band, whereas doping with Group 13 atoms adds positive holes (for a p-type semiconductor) by emptying some orbitals in the valence band. Placing these two types of semiconductors in contact with one another forms a p-n junction. Sandwiching a p-type portion between two n-type portions forms a transistor.
- › Liquid crystal phases flow like liquids but have molecules ordered like crystalline solids. Typically, the molecules have rodlike shapes, and their intermolecular forces keep them aligned. Thermotropic phases are prepared by heating the solid; lyotropic phases form when the solvent concentration is varied. The nematic, cholesteric, and smectic phases of liquid crystals differ in their molecular order. Liquid crystal applications depend on controlling the orientation of the molecules.
- › Ceramics are very resistant to heat and chemicals. Most are network covalent solids formed at high temperature from simple reactants. They add lightweight strength to other materials.
- › Polymers are extremely large molecules that adopt the shape of a random coil, as a result of intermolecular forces. A polymer sample has an average molar mass because it consists of chains with a range of lengths. The high viscosity of a polymer arises from attractions between chains or, in the case of a dissolved polymer, between chains and solvent. By varying the degrees of branching, crosslinking, and ordering (crystallinity), chemists tailor polymers with specific properties.
- › Nanotechnology employs nanoscale systems with sizes of 1–100 nm in a variety of applications.

CHAPTER REVIEW GUIDE

Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

Understand These Concepts

1. The distinction between bonding and intermolecular forces on the basis of Coulomb's law and the meaning of the van der Waals radius of an atom (§12.1)
2. The types and relative strengths of intermolecular forces acting in a substance (dipole-dipole, H bonding, dispersion), the impact of H bonding on physical properties, and the meaning of polarizability (§12.1)
3. How the interplay between kinetic and potential energy underlies the properties of the three states of matter and their phase changes (§12.2)
4. The processes involved, both within a phase and during a phase change, when heat is added or removed from a pure substance (§12.3)
5. The meaning of vapor pressure and how phase changes are dynamic equilibrium processes (§12.3)
6. How temperature and intermolecular forces influence vapor pressure (§12.3)
7. The relation between vapor pressure and boiling point (§12.3)
8. How a phase diagram shows the phases of a substance at differing conditions of pressure and temperature (§12.3)
9. The meanings of surface tension, capillarity, and viscosity and how intermolecular forces influence their magnitudes (§12.4)
10. How the important macroscopic properties of water arise from atomic and molecular properties (§12.5)
11. The structure of a crystal lattice and the characteristics of the three types of cubic unit cells (§12.6)
12. How packing of spheres gives rise to the hexagonal and cubic unit cells (§12.6)

13. Types of crystalline solids and how their intermolecular forces give rise to their properties (§12.6)
14. How band theory accounts for the properties of metals and the relative conductivities of metals, nonmetals, and metalloids (§12.6)
15. The structures, properties, and functions of modern materials (doped semiconductors, liquid crystals, ceramics, polymers, and nanostructures) (§12.7)

Master These Skills

1. Determining whether a substance can form H bonds and drawing the H-bonded structures (SP 12.1)
2. Predicting the types and relative strength of the bonding and intermolecular forces acting within a substance from its structure (SP 12.2)
3. Calculating the overall enthalpy change when heat is gained or lost by a pure substance (§12.3 and SP 12.3)
4. Using the Clausius-Clapeyron equation to examine the relationship between vapor pressure and temperature (SP 12.4)
5. Using a phase diagram to predict the phase changes of a substance (§12.3 and SP 12.5)
6. Finding the number of particles per unit cell and the coordination number of a crystalline solid (§12.6 and SP 12.6)
7. Calculating atomic radius from the density and/or crystal structure of an element (SPs 12.7, 12.8)

Key Terms

Page numbers appear in parentheses.

amorphous solid (493)	cubic closest packing (496)	insulator (506)	radius of gyration (R_g) (514)
atomic solid (502)	degree of polymerization (n) (513)	intermolecular forces (468)	random coil (514)
band theory (505)		ion-dipole force (469)	scanning tunneling microscopy (500)
body-centered cubic unit cell (494)	deposition (477)	ionic solid (502)	semiconductor (506)
boiling point (484)	dipole-dipole force (469)	lattice (493)	simple cubic unit cell (493)
branch (516)	dispersion (London) force (472)	liquid crystal (508)	sublimation (476)
capillarity (489)	doping (507)	melting (fusion) (476)	superconductivity (506)
ceramic (511)	elastomer (517)	melting point (485)	surface tension (488)
Clausius-Clapeyron equation (483)	face-centered cubic unit cell (495)	metallic solid (503)	triple point (486)
condensation (476)	freezing (476)	molecular solid (502)	unit cell (493)
conduction band (505)	heat of fusion ($\Delta H_{\text{fus}}^\circ$) (476)	monomer (513)	valence band (505)
conductor (506)	heat of sublimation ($\Delta H_{\text{subl}}^\circ$) (476)	nanotechnology (518)	van der Waals radius (468)
coordination number (493)	heat of vaporization ($\Delta H_{\text{vap}}^\circ$) (476)	network covalent solid (504)	vapor pressure (482)
copolymer (517)	heating-cooling curve (478)	packing efficiency (496)	vaporization (476)
critical point (486)	hexagonal closest packing (496)	phase (475)	viscosity (489)
crosslink (517)	hydrogen bond (H bond) (470)	phase change (476)	x-ray diffraction analysis (500)
crystal defect (507)		phase diagram (485)	
crystalline solid (493)		plastic (516)	
		polarizability (472)	
		polymer (macromolecule) (513)	

Key Equations and Relationships

Page number appears in parentheses.

12.1 Using the vapor pressure at one temperature to find the vapor pressure at another temperature (two-point form of the Clausius-Clapeyron equation) (483):

$$\ln \frac{P_2}{P_1} = \frac{\Delta H_{\text{vap}}}{R} \left(\frac{1}{T_1} - \frac{1}{T_2} \right)$$

CHAPTER PRACTICE TEST

The answers to the Practice Test problems are shown below and the full solutions can be found in the e-book.

- What is the strongest intermolecular force in a sample of PH_3 ?
(a) hydrogen bonds (b) dipole-dipole forces
(c) dispersion forces (d) ionic forces
- Which of the following can form hydrogen bonds?
(a) CH_3CN (b) HI (c) CH_3COOH (d) CHF_3
(e) $\text{H}_3\text{C}-\text{O}-\text{CH}_3$
- Which two of the following molecules have only dispersion intermolecular forces?
(a) CH_3OH (b) CO_2 (c) H_2S (d) N_2 (e) HBr
- Consider the following graph of vapor pressure versus temperature for two liquids.

Which of the following statements is true?

- Liquid A has stronger intermolecular forces and a higher boiling point than liquid B.
- Liquid B has stronger intermolecular forces and a higher boiling point than liquid A.
- Liquid A has stronger intermolecular forces and a lower boiling point than liquid B.
- Liquid B has stronger intermolecular forces and a lower boiling point than liquid A.

5. Which of the following is an indication of strong intermolecular forces in a liquid?

- Very low boiling point
- Very low surface tension
- Very low viscosity
- Very low vapor pressure
- All of these
- None of these

6. The atomic radius of aluminum is 143 pm and has a face-centered cubic unit cell. Calculate the density of aluminum.

- 2.72 g/cm³
- 3.67 g/cm³
- 4.96 g/cm³
- 2.24 g/cm³

7. The enthalpy of vaporization for CCl_4 is 29.82 kJ/mol. The vapor pressure of CCl_4 is 454 torr at 60.°C. Calculate the vapor pressure at 25°C.

- 189 torr
- 213 torr
- 512 torr
- 98 torr
- 128 torr

8. Which of the following solids is classified incorrectly?

- Cu: atomic solid
- CsBr: ionic solid
- SiO_2 (quartz): network covalent solid
- CH_4 : molecular solid

9. Calculate the amount of heat needed to convert 50.0 of ice at -10.0°C to liquid water at 10.0°C. $\Delta H_{\text{fus}}^\circ = 6.01 \text{ kJ/mol}$;

- mp = 0.0°C; $C_{\text{m(water, s)}} = 37.6 \text{ J/mol}\cdot^\circ\text{C}$; $C_{\text{m(water, l)}} = 75.3 \text{ J/mol}\cdot^\circ\text{C}$.
- 188 kJ
 - 31.5 kJ
 - 19.8 kJ
 - 25.4 kJ
 - 52.8 kJ

10. Which of the following is a semiconductor?

- copper
- chlorine
- selenium
- antimony
- sodium

Answers: 1. b; 2. c; 3. b, d; 4. b; 5. d; 6. a; 7. e; 8. a; 9. c; 10. d

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

12.1A

(c) No H bonding (H is not bonded to O in this molecule)

12.1B (a) No H bonding (H is not bonded to O in this molecule)

12.2A (a) Both molecules are polar (tetrahedral molecular geometry). Dipole-dipole and dispersion forces are present for both; CH_3Br has the higher boiling point because it has the larger molar mass.

(b) H bonding in $\text{CH}_3\text{CH}_2\text{CH}_2\text{OH}$, dipole-dipole and dispersion in both; $\text{CH}_3\text{CH}_2\text{CH}_2\text{OH}$ has the higher boiling point due to the H bonding.

(c) Both are nonpolar molecules. Dispersion forces; C_3H_8 has the higher boiling point because it has the larger molar mass.

12.2B (a) Dispersion and dipole-dipole forces in both, H bonding in $\text{CH}_3\text{CH}_2\text{OH}$; CH_3CHO has the lower boiling point, since it does not have H bonding.

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS (continued)

(b) SO_2 molecules, with a bent molecular geometry, are polar and have dispersion and dipole-dipole forces; CO_2 , which is a nonpolar linear molecule, has only dispersion forces. With the weaker forces, CO_2 has the lower boiling point.

(c) Dispersion and dipole-dipole forces in both molecules; H bonding in $\text{H}_2\text{N}-\text{C}(\text{O})\text{CH}_2\text{CH}_3$; $(\text{CH}_3)_2\text{N}-\text{CH}(\text{O})$ has the lower

boiling point, since it does not have H bonding.

12.3A The scenes represent solid water at -7.00°C melting to liquid water at 16.0°C , so heat is absorbed by the system (q is positive). There are three stages:

Stage 1, increasing the temperature of ice to the melting point: $\text{H}_2\text{O}(s) [-7.00^\circ\text{C}] \rightarrow \text{H}_2\text{O}(s) [0.00^\circ\text{C}]$:

$$q = n \times C_{m(\text{water}, s)} \times \Delta T = (2.25 \text{ mol})(37.6 \text{ J/mol} \cdot ^\circ\text{C}) [0^\circ\text{C} - (-7.00^\circ\text{C})] = 592 \text{ J} = 0.592 \text{ kJ}$$

Stage 2, melting the ice: $\text{H}_2\text{O}(s) [0.00^\circ\text{C}] \rightarrow \text{H}_2\text{O}(l) [0.00^\circ\text{C}]$:
 $q = n(\Delta H_{\text{fus}}^\circ) = (2.25 \text{ mol})(6.01 \text{ kJ/mol}) = 13.5 \text{ kJ}$

Stage 3, increasing the temperature of the water:

$\text{H}_2\text{O}(l) [0.00^\circ\text{C}] \rightarrow \text{H}_2\text{O}(l) [16.0^\circ\text{C}]$:

$$q = n \times C_{m(\text{water}, l)} \times \Delta T = (2.25 \text{ mol})(75.3 \text{ J/mol} \cdot ^\circ\text{C})(16.0^\circ\text{C} - 0^\circ\text{C}) = 2711 \text{ J} = 2.71 \text{ kJ}$$

$$\text{Total heat (kJ)} = 0.592 \text{ kJ} + 13.5 \text{ kJ} + 2.71 \text{ kJ} = 16.8 \text{ kJ}$$

12.3B The scenes represent gaseous bromine at 73.5°C condensing to liquid bromine at 23.8°C , so heat is released by the system (q is negative). First convert mass to moles:

$$\text{Amount (mol) Br}_2 = 47.94 \text{ g Br}_2 \times \frac{1 \text{ mol Br}_2}{159.8 \text{ g Br}_2} = 0.3000 \text{ mol Br}_2$$

There are three stages:

Stage 1, cooling the gas: $\text{Br}_2(g) [73.5^\circ\text{C}] \rightarrow \text{Br}_2(g) [59.5^\circ\text{C}]$:

$$q = n \times C_{m(\text{Br}_2, g)} \times \Delta T \\ = (0.3000 \text{ mol})(36.0 \text{ J/mol} \cdot ^\circ\text{C})(59.5^\circ\text{C} - 73.5^\circ\text{C}) \\ = -151 \text{ J} = -0.151 \text{ kJ}$$

Stage 2, condensing the gas to liquid at the boiling point:

$\text{Br}_2(g) [59.5^\circ\text{C}] \rightarrow \text{Br}_2(l) [59.5^\circ\text{C}]$:

$$q = n(-\Delta H_{\text{vap}}^\circ) = (0.3000 \text{ mol})(-29.6 \text{ kJ/mol}) = -8.88 \text{ kJ}$$

Stage 3, cooling the liquid: $\text{Br}_2(l) [59.5^\circ\text{C}] \rightarrow \text{Br}_2(l) [23.8^\circ\text{C}]$:

$$q = n \times C_{m(\text{Br}_2, l)} \times \Delta T = (0.3000 \text{ mol})(75.7 \text{ J/mol} \cdot ^\circ\text{C})(23.8^\circ\text{C} - 59.5^\circ\text{C}) \\ = -811 \text{ J} = -0.811 \text{ kJ}$$

$$\text{Total heat (kJ)} = -0.151 \text{ kJ} + (-8.88 \text{ kJ}) + (-0.811 \text{ kJ}) \\ = -9.84 \text{ kJ}$$

$$\begin{aligned} \mathbf{12.4A} \quad \ln \frac{P_2}{P_1} &= \frac{\Delta H_{\text{vap}}}{R} \left(\frac{1}{T_1} - \frac{1}{T_2} \right) \\ \ln \frac{P_2}{P_1} &= \left(\frac{40.65 \times 10^3 \text{ J/mol}}{8.314 \text{ J/mol} \cdot \text{K}} \right) \\ &\quad \times \left(\frac{1}{273.15 + 34.1 \text{ K}} - \frac{1}{273.15 + 85.5 \text{ K}} \right) \\ \ln \frac{P_2}{P_1} &= (4.89 \times 10^3 \text{ K})(4.66 \times 10^{-4} \text{ K}^{-1}) = 2.28 \\ \frac{P_2}{P_1} &= 9.8 \\ \frac{P_2}{40.1 \text{ torr}} &= 9.8; \quad P_2 = 40.1 \text{ torr} \times 9.8 = 390 \text{ torr} \end{aligned}$$

$$\begin{aligned} \mathbf{12.4B} \quad \ln \frac{P_2}{P_1} &= \frac{\Delta H_{\text{vap}}}{R} \left(\frac{1}{T_1} - \frac{1}{T_2} \right) \\ \ln \frac{10.00 \text{ kPa}}{24.50 \text{ kPa}} &= \frac{\Delta H_{\text{vap}}}{8.314 \text{ J/K} \cdot \text{mol}} \\ &\quad \times \left(\frac{1}{273.15 + 20.2 \text{ K}} - \frac{1}{273.15 + 0.95 \text{ K}} \right) \\ -0.8961 &= \frac{\Delta H_{\text{vap}}}{8.314 \text{ J/K} \cdot \text{mol}} \times (-0.0002394 \text{ K}^{-1}) \\ \Delta H_{\text{vap}} &= 3.11 \times 10^4 \text{ J/mol} = 31.1 \text{ kJ/mol} \end{aligned}$$

12.5A At the starting conditions (3×10^2 bar and 2000 K ; point c), the carbon sample is in the form of graphite. As the sample is heated at constant pressure, it melts at around 4500 K , then vaporizes at around 5000 K .

12.5B At the starting conditions (4600 K and 10^4 bar; point d), the carbon sample is in the form of graphite. As the sample is compressed at constant temperature, it melts at around 4×10^4 bar and then solidifies to diamond at around 2×10^5 bar.

12.6A (a) PbS: Pb^{2+} ions/unit cell = S^{2-} ions/unit cell = $(8 \times \frac{1}{8}) + (6 \times \frac{1}{2}) = 4 \text{ Pb}^{2+}$ and 4 S^{2-} ions; coordination number of each ion is 6.

(b) W: Atoms/unit cell = $(8 \times \frac{1}{8}) + 1 = 2$; coordination number is 8.

(c) Al: Atoms/unit cell = $(8 \times \frac{1}{8}) + (6 \times \frac{1}{2}) = 4$; coordination number is 12.

12.6B (a) K: Atoms/unit cell = $(8 \times \frac{1}{8}) + 1 = 2$; coordination number is 8.

(b) Pt: Atoms/unit cell = $(8 \times \frac{1}{8}) + (6 \times \frac{1}{2}) = 4$; coordination number is 12.

(c) CsCl: Cs^+ ions/unit cell = $(8 \times \frac{1}{8}) = 1$; Cl^- ions/unit cell = 1; coordination number of each ion is 8.

12.7A The packing efficiency in the face-centered cubic cell is 74%.

$$\begin{aligned} V \text{ of Co atom} &= \frac{4}{3} \pi r^3 = \frac{4}{3} (3.14) (125 \text{ pm})^3 \\ &= \frac{8.18 \times 10^6 \text{ pm}^3}{\text{atom}} \\ V \text{ of 1 mol of Co atoms (cm}^3\text{)} &= \frac{8.18 \times 10^6 \text{ pm}^3}{\text{atom}} \times \frac{6.022 \times 10^{23} \text{ atoms}}{\text{mol atoms}} \times \frac{1 \text{ cm}^3}{10^{30} \text{ pm}^3} \\ &= 4.93 \text{ cm}^3/\text{mol atoms} \end{aligned}$$

$$\begin{aligned} V \text{ of 1 mol of Co metal (cm}^3\text{)} &= \frac{4.93 \text{ cm}^3/\text{mol atoms}}{0.74} \\ &= 6.66 \text{ cm}^3/\text{mol Co metal} \end{aligned}$$

$$d \text{ of Co metal} = \frac{58.93 \text{ g}}{\text{mol}} \times \frac{1 \text{ mol}}{6.66 \text{ cm}^3} = 8.85 \text{ g/cm}^3$$

12.7B The packing efficiency in the body-centered cubic cell is 68%.

$$\begin{aligned} \text{Avogadro's no.} &= \frac{55.85 \text{ g Fe}}{1 \text{ mol Fe}} \times \frac{1 \text{ cm}^3}{7.874 \text{ g Fe}} \times 0.68 \\ &\quad \times \frac{1 \text{ Fe atom}}{8.38 \times 10^{-24} \text{ cm}^3} \\ &= 5.8 \times 10^{23} \text{ Fe atoms/mol Fe} \end{aligned}$$

12.8A From Figure 12.30,

$$A \text{ (nm)} = \frac{4r}{\sqrt{3}} = \frac{4(126 \text{ pm})}{\sqrt{3}} = 291 \text{ pm} \times \frac{1 \text{ nm}}{1000 \text{ pm}} = 0.291 \text{ nm}$$

12.8B $A = \sqrt{8}r$

$$r = A/\sqrt{8} = 0.405 \text{ nm}/\sqrt{8} = 0.143 \text{ nm} = 143 \text{ pm}$$

PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

Types of Intermolecular Forces

(Sample Problems 12.1 and 12.2)

Concept Review Questions

12.1 Why are covalent bonds typically much stronger than intermolecular forces?

12.2 (a) Name the type of force depicted in each scene below.
(b) Rank the forces in order of increasing strength.

12.3 Oxygen and selenium are members of Group 16. Water forms H bonds, but H_2Se does not. Explain.

12.4 In solid I_2 , is the distance between the two I nuclei of one I_2 molecule longer or shorter than the distance between two I nuclei of adjacent I_2 molecules? Explain.

12.5 Polar molecules exhibit dipole-dipole forces. Do they also exhibit dispersion forces? Explain.

12.6 Distinguish between *polarizability* and *polarity*. How does each influence intermolecular forces?

12.7 How can one nonpolar molecule induce a dipole in a nearby nonpolar molecule?

Skill-Building Exercises (grouped in similar pairs)

12.8 What is the strongest interparticle force in each substance?

(a) CH_3OH (b) CCl_4 (c) Cl_2

12.9 What is the strongest interparticle force in each substance?

(a) H_3PO_4 (b) SO_2 (c) MgCl_2

12.10 What is the strongest interparticle force in each substance?

(a) CH_3Cl (b) CH_3CH_3 (c) NH_3

12.11 What is the strongest interparticle force in each substance?

(a) Kr (b) BrF (c) H_2SO_4

12.12 Which member of each pair of compounds forms intermolecular H bonds? Draw the H-bonded structures in each case:

(a) CH_3CHCH_3 or CH_3SCH_3 (b) HF or HBr
OH

12.13 Which member of each pair of compounds forms intermolecular H bonds? Draw the H-bonded structures in each case:

(a) $(\text{CH}_3)_2\text{NH}$ or $(\text{CH}_3)_3\text{N}$ (b) $\text{HOCH}_2\text{CH}_2\text{OH}$ or $\text{FCH}_2\text{CH}_2\text{F}$

12.14 Which forces oppose vaporization of each substance?

(a) Hexane (b) Water (c) SiCl_4

12.15 Which forces oppose vaporization of each substance?

(a) Br_2 (b) SbH_3 (c) CH_3NH_2

12.16 Which species in each pair has the greater polarizability? Explain.

(a) Ne or Ar (b) $\text{CH}_2=\text{CH}_2$ or CH_3-CH_3 (c) H_2O or H_2Se

12.17 Which species in each pair has the greater polarizability? Explain.

(a) HI or HCl (b) CH_3CH_3 or $\text{CH}_3\text{CH}_2\text{CH}_3$ (c) CCl_4 or CF_4

12.18 Which liquid in each pair has the *higher* vapor pressure at a given temperature? Explain.

(a) C_2H_6 or C_4H_{10} (b) $\text{CH}_3\text{CH}_2\text{OH}$ or $\text{CH}_3\text{CH}_2\text{F}$
(c) NH_3 or PH_3

12.19 Which liquid in each pair has the *lower* vapor pressure at a given temperature? Explain.

(a) $\text{HOCH}_2\text{CH}_2\text{OH}$ or $\text{CH}_3\text{CH}_2\text{CH}_2\text{OH}$
(b) CH_3COOH or $(\text{CH}_3)_2\text{C}=\text{O}$ (c) HF or HCl

12.20 Which substance has the *lower* boiling point? Explain.

(a) LiCl or HCl (b) NH_3 or PH_3 (c) Xe or I₂

12.21 Which substance has the *higher* boiling point? Explain.

(a) $\text{CH}_3\text{CH}_2\text{OH}$ or $\text{CH}_3\text{CH}_2\text{CH}_3$ (b) NO or N₂
(c) H_2S or H_2Te

12.22 Which substance has the *lower* boiling point? Explain.

(a) $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_3$ or $\text{CH}_2=\text{CH}_2$ (b) NaBr or PBr₃
 $\text{CH}_2=\text{CH}_2$

(c) H_2O or HBr

12.23 Which substance has the *higher* boiling point? Explain.

(a) CH_3OH or CH_3CH_3 (b) FNO or ClNO

(c) $\text{F}-\text{C}=\text{C}-\text{F}$ or $\text{H}-\text{C}=\text{C}-\text{H}$
 $\text{H} \quad \text{H} \quad \text{F} \quad \text{H}$

Problems in Context

12.24 For pairs of molecules in the gas phase, average H-bond dissociation energies are 17 kJ/mol for NH_3 , 22 kJ/mol for H_2O , and 29 kJ/mol for HF. Explain this increase in H-bond strength.

12.25 Dispersion forces are the only intermolecular forces present in motor oil, yet it has a high boiling point. Explain.

12.26 Why does the antifreeze ingredient ethylene glycol ($\text{HOCH}_2\text{CH}_2\text{OH}$; $M = 62.07 \text{ g/mol}$) have a boiling point of 197.6°C , whereas propanol ($\text{CH}_3\text{CH}_2\text{CH}_2\text{OH}$; $M = 60.09 \text{ g/mol}$), a compound with a similar molar mass, has a boiling point of only 97.4°C ?

An Overview of Physical States and Phase Changes

Concept Review Questions

12.27 How does the energy of attraction between particles compare with their energy of motion in a gas and in a solid? As part of your answer, identify two macroscopic properties that differ between a gas and a solid.

12.28 (a) Why are gases more easily compressed than liquids?
(b) Why do liquids have a greater ability to flow than solids?

12.29 What type of forces, intramolecular or intermolecular,
(a) Prevent ice cubes from adopting the shape of their container?
(b) Are overcome when ice melts?
(c) Are overcome when liquid water is vaporized?
(d) Are overcome when gaseous water is converted to hydrogen gas and oxygen gas?

12.30 (a) Why is the heat of fusion (ΔH_{fus}) of a substance smaller than its heat of vaporization (ΔH_{vap})?
(b) Why is the heat of sublimation (ΔH_{subl}) of a substance greater than its ΔH_{vap} ?
(c) At a given temperature and pressure, how does the magnitude of the heat of vaporization of a substance compare with that of its heat of condensation?

Skill-Building Exercises (grouped in similar pairs)

12.31 Which forces are intramolecular and which intermolecular?
(a) Those preventing oil from evaporating at room temperature
(b) Those preventing butter from melting in a refrigerator
(c) Those allowing silver to tarnish
(d) Those preventing O_2 in air from forming O atoms

12.32 Which forces are intramolecular and which intermolecular?
(a) Those allowing fog to form on a cool, humid evening
(b) Those allowing water to form when H_2 is sparked
(c) Those allowing liquid benzene to crystallize when cooled
(d) Those responsible for the low boiling point of hexane

12.33 Name the phase change in each of these events: (a) Dew appears on a lawn in the morning. (b) Icicles change into liquid water. (c) Wet clothes dry on a summer day.

12.34 Name the phase change in each of these events: (a) A diamond film forms on a surface from gaseous carbon atoms in a vacuum. (b) Mothballs in a bureau drawer disappear over time. (c) Molten iron from a blast furnace is cast into ingots (“pigs”).

Problems in Context

12.35 Liquid propane, a widely used fuel, is produced by compressing gaseous propane. During the process, approximately 15 kJ of energy is released for each mole of gas liquefied. Where does this energy come from?

12.36 Many heat-sensitive and oxygen-sensitive solids, such as camphor, are purified by warming under vacuum. The solid vaporizes directly, and the vapor crystallizes on a cool surface. What phase changes are involved in this method?

Quantitative Aspects of Phase Changes

(Sample Problems 12.3–12.5)

Concept Review Questions

12.37 Describe the changes (if any) in potential energy and in kinetic energy among the molecules when gaseous PCl_3 condenses to a liquid at a fixed temperature.

12.38 When benzene is at its melting point, two processes occur simultaneously and balance each other. Describe these processes on the macroscopic and molecular levels.

12.39 Liquid hexane (bp = 69°C) is placed in a closed container at room temperature. At first, the pressure of the vapor phase increases, but, after a short time, it stops changing. Why?

12.40 Explain the effect of strong intermolecular forces on each of these parameters: (a) critical temperature; (b) boiling point; (c) vapor pressure; (d) heat of vaporization.

12.41 Match each numbered point in the phase diagram for compound Q with the correct molecular scene below:

12.42 A liquid is in equilibrium with its vapor in a closed vessel at a fixed temperature. The vessel is connected by a stopcock to an evacuated vessel. When the stopcock is opened, will the final pressure of the vapor be different from the initial value if (a) some liquid remains; (b) all the liquid is first removed? Explain.

12.43 The phase diagram for substance A has a solid-liquid line with a positive slope, and that for substance B has a solid-liquid line with a negative slope. What macroscopic property can distinguish A from B?

12.44 Why does water vapor at 100°C cause a more severe burn than liquid water at 100°C ?

Skill-Building Exercises (grouped in similar pairs)

12.45 From the data below, calculate the total heat (in J) needed to convert 22.00 g of ice at -6.00°C to liquid water at 0.500°C :

mp at 1 atm:	0.0°C	$\Delta H_{\text{fus}}^\circ$:	6.01 kJ/mol
c_{liquid}° :	$4.18 \text{ J/g}\cdot^\circ\text{C}$	c_{solid}° :	$2.09 \text{ J/g}\cdot^\circ\text{C}$

12.46 From the data below, calculate the total heat (in J) needed to convert 0.333 mol of gaseous ethanol at 300°C and 1 atm to liquid ethanol at 25.0°C and 1 atm:

bp at 1 atm: 78.24°C $\Delta H_{\text{vap}}^\circ$: 38.56 kJ/mol
 c_{gas} : 1.43 J/g·°C c_{liquid} : 2.438 J/g·°C

12.47 A liquid has a $\Delta H_{\text{vap}}^\circ$ of 35.5 kJ/mol and a boiling point of 122°C at 1.00 atm. What is its vapor pressure at 113°C?

12.48 Diethyl ether has a $\Delta H_{\text{vap}}^\circ$ of 26.52 kJ/mol and a vapor pressure of 0.703 atm at 25.0°C. What is its vapor pressure at 95.0°C?

12.49 What is the $\Delta H_{\text{vap}}^\circ$ of a liquid that has a vapor pressure of 621 torr at 85.2°C and a boiling point of 95.6°C at 1 atm?

12.50 Methane (CH_4) has a boiling point of -161.5°C at 1 atm and a vapor pressure of 42.8 atm at -100°C . What is the heat of vaporization of CH_4 ?

12.51 Use these data to draw a qualitative phase diagram for ethylene (C_2H_4). Is $\text{C}_2\text{H}_4(\text{s})$ more or less dense than $\text{C}_2\text{H}_4(\text{l})$?

bp at 1 atm: -103.7°C
 mp at 1 atm: -169.16°C
 Critical point: 9.9°C and 50.5 atm
 Triple point: -169.17°C and 1.20×10^{-3} atm

12.52 Use these data to draw a qualitative phase diagram for H_2 . Does H_2 sublime at 0.05 atm? Explain.

mp at 1 atm: 13.84 K
 bp at 1 atm: 20.12 K
 Triple point: 13.95 K and 0.07 atm
 Critical point: 32.8 K and 12.7 atm
 Vapor pressure of solid at 10 K: 0.001 atm

12.53 The phase diagram for sulfur is shown below.

(a) Give a set of conditions under which it is possible to sublime the rhombic form of solid sulfur.

(b) Describe the phase changes that a sample of sulfur undergoes at 1 atm when it is heated from 90°C to 450°C .

12.54 The phase diagram for xenon is shown below.

(a) What phase is xenon in at room temperature and pressure?

(b) Describe the phase changes that a sample of xenon undergoes at -115°C as it is compressed from 0.5 atm to 25 atm. (The critical pressure of xenon is 58 atm.)

Problems in Context

12.55 Sulfur dioxide is produced in enormous amounts for sulfuric acid production. It melts at -73°C and boils at -10°C . Its $\Delta H_{\text{fus}}^\circ$ is 8.619 kJ/mol, and its $\Delta H_{\text{vap}}^\circ$ is 25.73 kJ/mol. The specific heat capacities of the liquid and gas are 0.995 J/g·K and 0.622 J/g·K, respectively. How much heat is required to convert 2.500 kg of solid SO_2 at the melting point to a gas at 60°C ?

12.56 Butane is a common fuel used in cigarette lighters and camping stoves. Normally supplied in metal containers under pressure, the fuel exists as a mixture of liquid and gas, so high temperatures may cause the container to explode. At 25.0°C , the vapor pressure of butane is 2.3 atm. What is the pressure in the container at 135°C ($\Delta H_{\text{vap}}^\circ = 22.4$ kJ/mol)?

12.57 Use Figure 12.19 to answer the following:

(a) Carbon dioxide is sold in steel cylinders under a pressure of approximately 20 atm. Is there liquid CO_2 in the cylinder at room temperature ($\sim 20^\circ\text{C}$)? At 40°C ? At -40°C ? At -120°C ?

(b) Carbon dioxide is also sold as solid chunks, called *dry ice*, in insulated containers. If the chunks are warmed by leaving them in an open container at room temperature, will they melt?

(c) If a container is nearly filled with dry ice and then sealed and warmed to room temperature, will the dry ice melt?

(d) If dry ice is compressed at a temperature below its triple point, will it melt?

Properties of the Liquid State

Concept Review Questions

12.58 Before the phenomenon of surface tension was understood, physicists described the surface of water as being covered with a "skin." What causes this skinlike phenomenon?

12.59 Small, equal-sized drops of oil, water, and mercury lie on a waxed floor. How does each liquid behave? Explain.

12.60 Why does an aqueous solution of ethanol ($\text{CH}_3\text{CH}_2\text{OH}$) have a lower surface tension than water?

12.61 Why are units of energy per area (J/m^2) used for surface tension values?

12.62 Does the *strength* of the intermolecular forces in a liquid change as the liquid is heated? Explain. Why does a liquid's viscosity decrease with rising temperature?

Skill-Building Exercises (grouped in similar pairs)

12.63 Rank the following in order of *increasing* surface tension at a given temperature, and explain your ranking:

- (a) $\text{CH}_3\text{CH}_2\text{CH}_2\text{OH}$ (b) $\text{HOCH}_2\text{CH}(\text{OH})\text{CH}_2\text{OH}$
 (c) $\text{HOCH}_2\text{CH}_2\text{OH}$

12.64 Rank the following in order of *decreasing* surface tension at a given temperature, and explain your ranking:

- (a) CH_3OH (b) CH_3CH_3 (c) $\text{H}_2\text{C}=\text{O}$

12.65 Rank the compounds in Problem 12.63 in order of *decreasing* viscosity at a given temperature; explain your ranking.

12.66 Rank the compounds in Problem 12.64 in order of *increasing* viscosity at a given temperature; explain your ranking.

Problems in Context

12.67 Soil vapor extraction (SVE) is used to remove volatile organic pollutants, such as chlorinated solvents, from soil at hazardous waste sites. Vent wells are drilled, and a vacuum pump is applied to the subsurface. (a) How does this method remove pollutants? (b) Why does heating combined with SVE speed the process?

12.68 Use Figure 12.11 to answer the following: (a) Does it take more heat to melt 12.0 g of CH_4 or 12.0 g of Hg ? (b) Does it take more heat to vaporize 12.0 g of CH_4 or 12.0 g of Hg ? (c) What is the principal intermolecular force in each sample?

12.69 Pentanol ($\text{C}_5\text{H}_{11}\text{OH}$; $\mathcal{M} = 88.15 \text{ g/mol}$) has nearly the same molar mass as hexane (C_6H_{14} ; $\mathcal{M} = 86.17 \text{ g/mol}$) but is more than 12 times as viscous at 20°C . Explain.

The Uniqueness of Water**Concept Review Questions**

12.70 For what types of substances is water a good solvent? For what types is it a poor solvent? Explain.

12.71 A water molecule can engage in as many as four H bonds. Explain.

12.72 Warm-blooded animals have a narrow range of body temperature because their bodies have a high water content. Explain.

12.73 What property of water keeps plant debris on the surface of lakes and ponds? What is the ecological significance of this?

12.74 A drooping plant can be made to stand upright by watering the ground around it. Explain.

12.75 Describe the molecular basis of the property of water responsible for the presence of ice on the surface of a frozen lake.

12.76 Describe in molecular terms what occurs when ice melts.

The Solid State: Structure, Properties, and Bonding

(Sample Problems 12.6–12.8)

Concept Review Questions

12.77 What is the difference between an amorphous solid and a crystalline solid on the macroscopic and molecular levels? Give an example of each.

12.78 How are a solid's unit cell and crystal structure related?

12.79 For structures consisting of identical atoms, how many atoms are contained in a simple cubic, a body-centered cubic, and a face-centered cubic unit cell? Explain how you obtained the values.

12.80 An element has a crystal structure in which the width of the cubic unit cell equals the diameter of an atom. What type of unit cell does it have?

12.81 What specific difference in the positioning of spheres gives a crystal structure based on the face-centered cubic unit cell less empty space than one based on the body-centered cubic unit cell?

12.82 Both solid Kr and solid Cu consist of individual atoms. Why do their physical properties differ so much?

12.83 What is the energy gap in band theory? Compare its size in superconductors, conductors, semiconductors, and insulators.

12.84 Predict the effect (if any) of an increase in temperature on the electrical conductivity of (a) a conductor; (b) a semiconductor; (c) an insulator.

12.85 Besides the type of unit cell, what information is needed to find the density of a solid consisting of identical atoms?

Skill-Building Exercises (grouped in similar pairs)

12.86 What type of unit cell does each metal use in its crystal lattice? (The number of atoms per unit cell is given in parentheses.)

- (a) Ni (4) (b) Cr (2) (c) Ca (4)

12.87 What is the number of atoms per unit cell for each metal?

- (a) Polonium, Po (b) Manganese, Mn (c) Silver, Ag

12.88 Calcium crystallizes in a cubic closest packed structure. If the atomic radius of calcium is 197 pm, find the density of the solid.

12.89 Chromium adopts the body-centered cubic unit cell in its crystal structure. If the density of chromium is 7.14 g/cm^3 , find its atomic radius.

12.90 When cadmium oxide reacts to form cadmium selenide, a change in unit cell occurs, as depicted below:

(a) What is the change in unit cell?

(b) Does the coordination number of cadmium change? Explain.

12.91 As molten iron cools to 1674 K, it adopts one type of cubic unit cell; then, as the temperature drops below 1181 K, it changes to another, as depicted below:

- (a) What is the change in unit cell?
 (b) Which crystal structure has the greater packing efficiency?

12.92 Potassium adopts the body-centered cubic unit cell in its crystal structure. If the atomic radius of potassium is 227 pm, find the edge length of the unit cell.

12.93 Lead adopts the face-centered cubic unit cell in its crystal structure. If the edge length of the unit cell is 495 pm, find the atomic radius of lead.

12.94 Of the five major types of crystalline solid, which does each of the following form, and why: (a) Ni; (b) F₂; (c) CH₃OH; (d) Sn; (e) Si; (f) Xe?

12.95 Of the five major types of crystalline solid, which does each of the following form, and why: (a) SiC; (b) Na₂SO₄; (c) SF₆; (d) cholesterol (C₂₇H₄₅OH); (e) KCl; (f) BN?

12.96 Zinc oxide adopts the zinc blende crystal structure (Figure P12.96). How many Zn²⁺ ions are in the ZnO unit cell?

12.97 Calcium sulfide adopts the sodium chloride crystal structure (Figure P12.97). How many S²⁻ ions are in the CaS unit cell?

Figure P12.96

Figure P12.97

12.98 Zinc selenide (ZnSe) crystallizes in the zinc blende structure (see Figure P12.96) and has a density of 5.42 g/cm³.

- (a) How many Zn and Se ions are in each unit cell?
 (b) What is the mass of a unit cell?
 (c) What is the volume of a unit cell?
 (d) What is the edge length of a unit cell?

12.99 An element crystallizes in a face-centered cubic lattice, and it has a density of 1.45 g/cm³. The edge of its unit cell is 4.52×10^{-8} cm.

- (a) How many atoms are in each unit cell?
 (b) What is the volume of a unit cell?
 (c) What is the mass of a unit cell?
 (d) Calculate an approximate atomic mass for the element.

12.100 Classify each of the following as a conductor, an insulator, or a semiconductor: (a) phosphorus; (b) mercury; (c) germanium.

12.101 Classify each of the following as a conductor, an insulator, or a semiconductor: (a) carbon (graphite); (b) sulfur; (c) platinum.

12.102 Predict the effect (if any) of an increase in temperature on the electrical conductivity of (a) antimony; (b) tellurium; (c) bismuth.

12.103 Predict the effect (if any) of a decrease in temperature on the electrical conductivity of (a) silicon; (b) lead; (c) germanium.

Problems in Context

12.104 Polonium, the Period 6 member of Group 16, is a rare radioactive metal that is the only element with a crystal structure based on the simple cubic unit cell. If its density is 9.142 g/cm³, calculate an approximate atomic radius for polonium.

12.105 The coinage metals—copper, silver, and gold—crystallize in a cubic closest packed structure. Use the density of copper (8.95 g/cm³) and its molar mass (63.55 g/mol) to calculate an approximate atomic radius for copper.

12.106 One of the most important enzymes in the world—nitrogenase, the plant protein that catalyzes nitrogen fixation—contains active clusters of iron, sulfur, and molybdenum atoms. Crystalline molybdenum (Mo) has a body-centered cubic unit cell (d of Mo = 10.28 g/cm³). (a) Determine the edge length of the unit cell. (b) Calculate the atomic radius of Mo.

12.107 Tantalum (Ta; d = 16.634 g/cm³ and $\mathcal{M}$ = 180.9479 g/mol) has a body-centered cubic structure with a unit-cell edge length of 3.3058 Å. Use these data to calculate Avogadro's number.

Advanced Materials

Concept Review Questions

12.108 In the process of doping a semiconductor, certain impurities are added to increase the electrical conductivity. Explain this process for an n-type and a p-type semiconductor.

12.109 State two molecular characteristics of substances that typically form liquid crystals. How is each related to function?

12.110 Distinguish between isotropic and anisotropic substances. To which category do liquid crystals belong?

12.111 How are the properties of high-tech ceramics the same as those of traditional clay ceramics, and how are they different? Refer to specific substances in your answer.

12.112 Why is the average molar mass of a polymer sample different from the molar mass of an individual chain?

12.113 How does the random coil shape relate to the radius of gyration of a polymer chain?

12.114 What factor(s) influence(s) the viscosity of a polymer solution? What factor(s) influence(s) the viscosity of a molten polymer? What is a polymer glass?

12.115 Use an example to show how branching and crosslinking can affect the physical behavior of a polymer.

Skill-Building Exercises (grouped in similar pairs)

12.116 Silicon and germanium are both semiconducting elements from Group 14 that can be doped to improve their conductivity. Would each of the following form an n-type or a p-type semiconductor: (a) Ge doped with P; (b) Si doped with In?

12.117 Would each of the following form an n-type or a p-type semiconductor: (a) Ge doped with As; (b) Si doped with B?

12.118 The repeat unit of the polystyrene of a coffee cup has the formula C₆H₅CHCH₂. If the molar mass of the polymer is 3.5×10^5 g/mol, what is the degree of polymerization?

12.119 The monomer of poly(vinyl chloride) has the formula C₂H₃Cl. If there are 1565 repeat units in a single chain of the polymer, what is the molecular mass (in amu) of that chain?

12.120 The polypropylene (repeat unit CH₃CHCH₂) in a plastic toy has a molar mass of 2.8×10^5 g/mol, and the length of a repeat unit is 0.252 pm. Calculate the radius of gyration.

12.121 The polymer that is used to make 2-L soda bottles [poly(ethylene terephthalate)] has a repeat unit with molecular formula C₁₀H₈O₄ and a length of 1.075 nm. Calculate the radius of gyration of a chain with a molar mass of 2.30×10^4 g/mol.

Comprehensive Problems

12.122 A 0.75-L bottle is cleaned, dried, and closed in a room where the air is 22°C and has 44% relative humidity (that is, the water vapor in the air is 0.44 of the equilibrium vapor pressure at 22°C). The bottle is then taken outside and stored at 0.0°C.

- (a) What mass of liquid water condenses inside the bottle?
 (b) Would liquid water condense at 10°C? (See Table 5.2.)
